
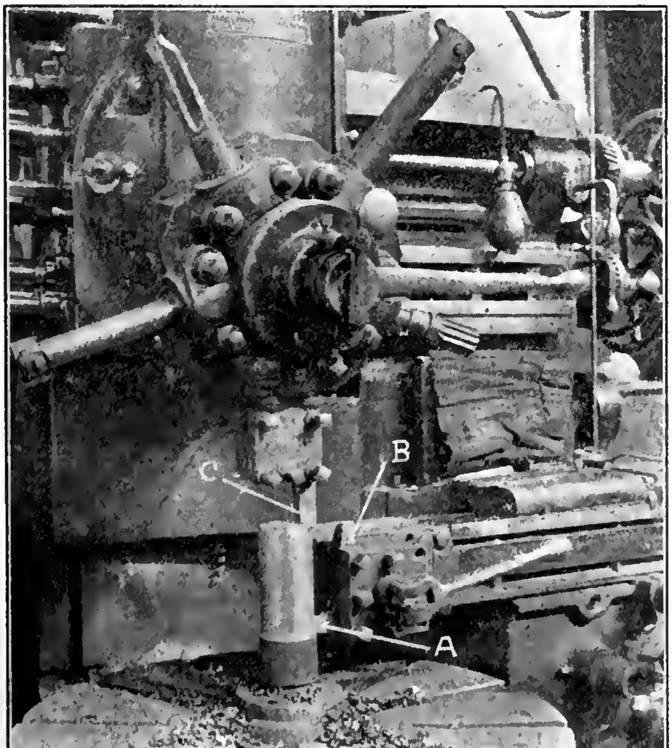

FIG. 1. ROUGH TURNING SHELL FORGING ON "BULLARD" VERTICAL TURRET LATHE.

Rapid travel now takes the tool A up to the base of the shell, when a quarter-

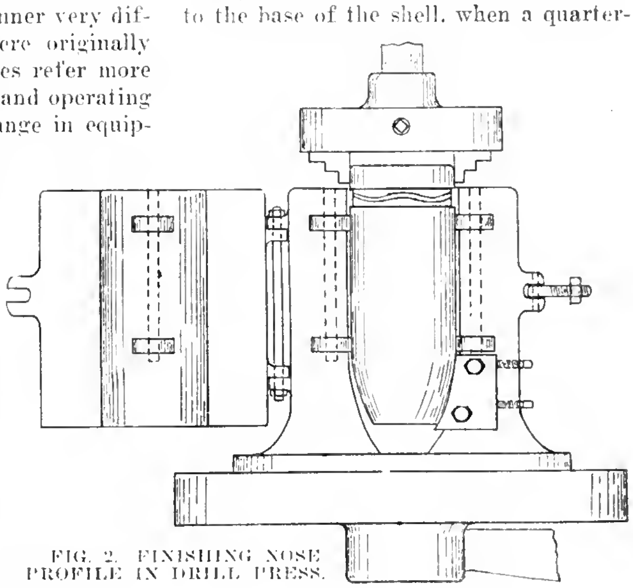

FIG. 2. FINISHING NOSE PROFILE IN DRILL PRESS.

turn of the tool box brings tool B into position, when a finish cut is taken across the groove. The operation of rough turning is now completed, the groove being machined afterward.

The method adopted for waving is quite a departure from recognized practice, although the variety of methods already in use by shell makers are quite numerous. A helical spring and ball thrust bearing on the tail end of the spindle maintain the spindle in its normal position. The shell is gripped base end in the chuck, a pipe centre truing up nose from the inside. A rapid movement of the tailstock spindle is obtained by hand lever. The pipe centre slides inside of spindle and is backed by a helical spring. The undercutting tool in front of the work is of the solid type which is fed straight in to the proper depth and then moved sideways. This tool is operated first, the sidewise movement of the carriage being controlled by stops. A wedge like plate is interposed between the left hand stop and the end of the carriage. This plate may be swung round on its hinge and allows of accurate adjustment being made when setting the tool.

Reversed Waving

As soon as the undercut is machined, the tool is withdrawn, the carriage held

towards one side against the stop, and with the spindle reversed, a hand lever is pressed which forces a roller between the end of the front spindle bearing and a cam plate on the back of the chuck. The springs A and B are now in action, and the shell is moved sideways in front of the waving tool which is back of the shell, and which is fed in by hand in the usual manner.

This method of waving provides a very smooth running machine which turns out smooth waves with no chattering, and runs at a high speed. The use of springs instead of weights is preferable because of the absence of inertia and momentum which cause greater wear on the cam.

The idea of holding the tool steady with the carriage in a stationary position against a stop eliminates all chatter such as sometimes occurs on reversal with reciprocating carriages on tool holders.

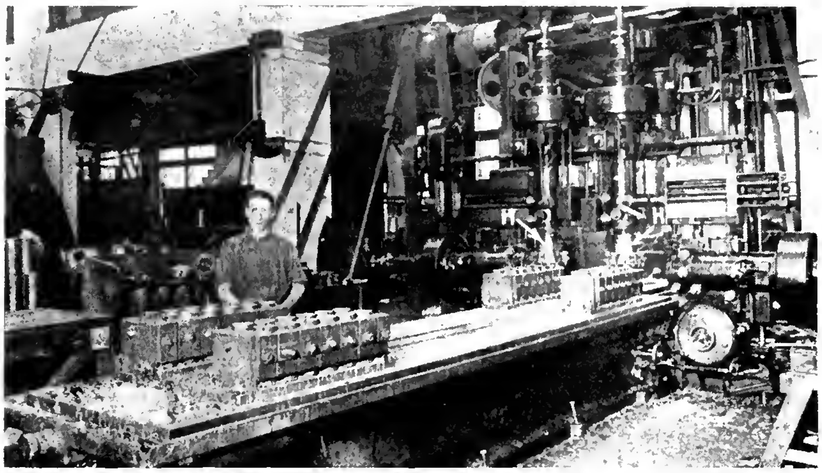

FIG. 3. ROUGH MACHINING BASES IN HORIZONTAL MILLING MACHINE.

Machines

It has been the experience of many shell makers that the limiting factor of grinding success is the necessity of truing up the curved portion of the wheel A skilled operator using a piece of carborundum crystal has been known to get almost sixty shells ground without bringing the truing up device into play and using the diamond. Average operators run about half, but the occasional loss of diamonds is an objectionable feature. This firm, like others, has accordingly discarded the grinder for the nose profile, retaining it for the cylindrical portion only. After nosing, the shell is rough turned to profile with a flat forming tool, and then ground on the parallel portion, after which it is chucked by the base in a drilling machine, nose down, and forced down into a fixture which has three pairs of guiding rollers, and is provided with a flat forming tool for finish scraping the nose to shape. One pair of the rollers is hinged on a gate which opens to allow the shell to enter and leave the fixture. The action of the fixture is identically that of a huge pencil sharpener (see Fig. 2).

A large 4-spindle "Ingersoll" milling machine has been employed for rough machining the bases, and until recently it operated with the two vertical heads only; the side heads remaining idle as shown in photograph, Fig. 3. As will be noticed here, the shells are held in fixtures each holding 12 shells, and arranged in pairs at each end of the table so that in machining a lot of 24 shells, the table had to travel sufficiently far to pass six shells across the cutter.

A Striking Comparison

Reference to Fig. 4 will show clearly how the machine was utilized to its full capacity. The fixtures at either end of the table were redesigned so as to each hold four groups of seven shells each. These are arranged so that the cutter heads come into action on their own group of shells simultaneously, the vertical heads projecting in advance of the side heads.

The difference in the methods of clamping the work in Figs. 3 and 4 call for special mention. In Fig. 3 the original fixtures had 24 nuts which had to be loosened and tightened each travel of the table. The present fixtures require 12 set screws only to be adjusted.

With a table travel of six shell diameters plus clearance, this machine formerly completed 24 pieces. With a table travel of four shell diameters without clearance this machine now completes 28 shells. Neglecting clearance spaces in fixtures this represents an increase in rate of output of approximately 75 per cent.

Machine Tools Extraordinary

If any self-respecting machine tool builder were to be told that a gas engine frame with a few fixtures added made a first class boring machine, he would have serious doubts regarding the sanity of his informant. Fig. 5 is a sketch of such a machine in actual use. It was constructed after trials with a converted bolt cutter proved successful. The cylinder A forms a substantial support for the cutter spindle B, a suitable bearing being mounted at each end. In the crankshaft supports is mounted a yoke C, the upper and lower portions of which support two fixed slide rods D. One end of these slide rods is fastened to the cylinder head, and the other end extends to the end of the bedplate where a yoke E is mounted, in the centre of which is mounted the feed gear.

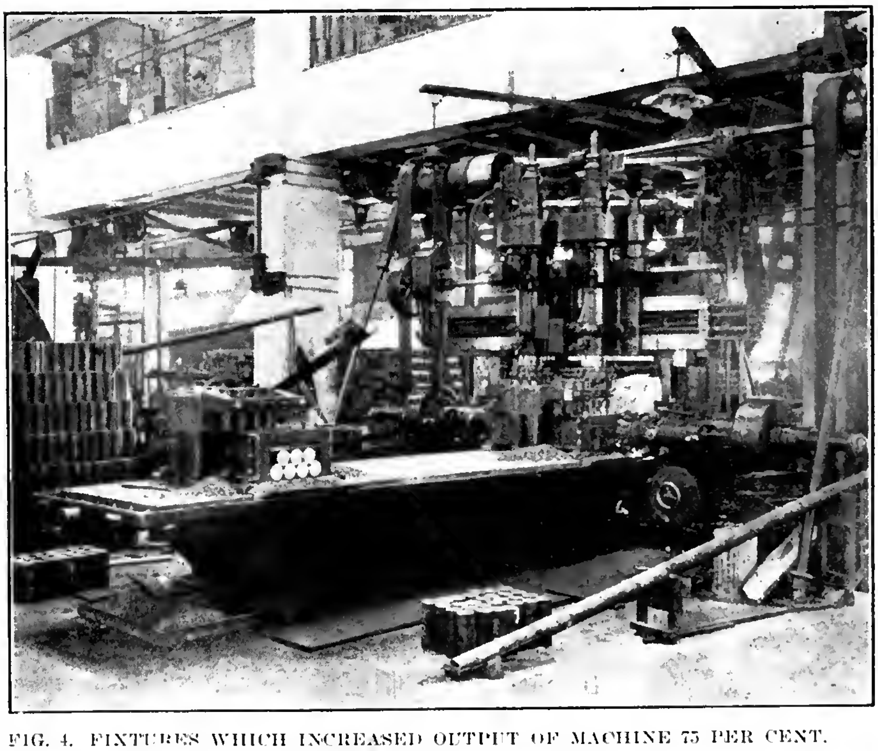

FIG. 4. FIXTURES WHICH INCREASED OUTPUT OF MACHINE 75 PER CENT.

Between the cylinder head and the yoke C a sliding chuck G, is mounted on the slide rods. Rapid traverse of this chuck along the slide rods is obtained by means of a link and handwheel H.

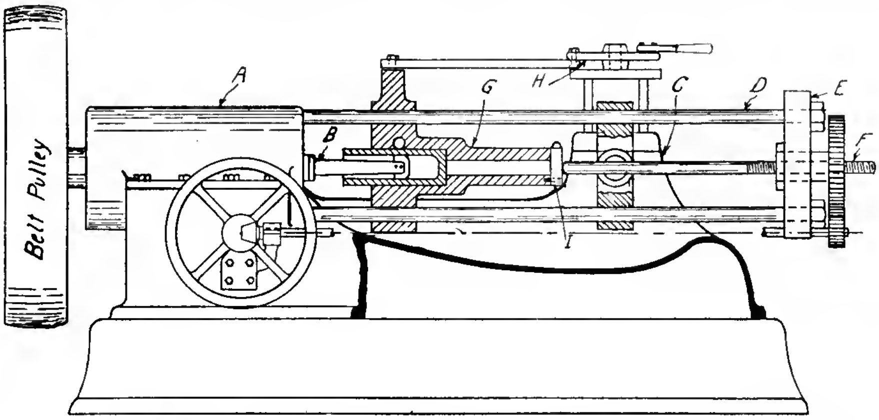

FIG. 5. SHELL BORING MACHINE BUILT FROM GASOLINE ENGINE PARTS.

The chuck G, is made a close fit for the shell which is tightened by one blow of a hammer on a taper pin. When the chuck G, is moved away from the cutter bar B to let the shell into position, the plate I is swung clear, allowing the body of the chuck to telescope over feed spindle F.

The shell is now slipped over the cutter bar B, the chuck G, moved over the shell and taper pin tightened. Plate I is swung back into line with spindle F, and boring commenced, on completion of which the operations are reversed, the shell remaining on the cutter bar while the chuck is drawn away.

Experiments with cutters have shown the feasibility of doing this operation with one cutter only, the extra output more than off-setting upkeep of cutters. Owing to the lack of a large enough pulley, this machine takes 56 seconds per shell for boring to gauge, but when properly equipped and operated, it is expected to surpass even that satisfactory performance.

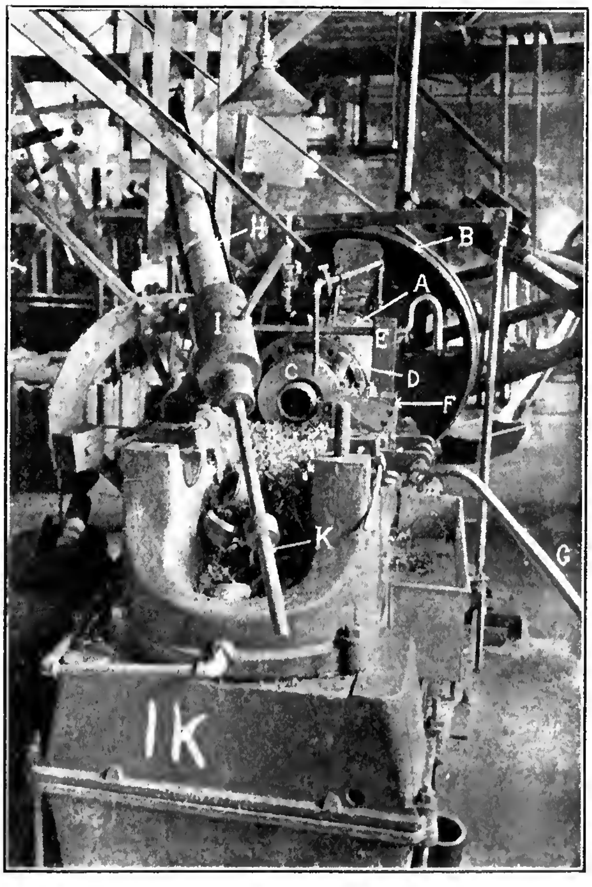

FIG. 6. TRANSFORMED GAS ENGINE DOING DUTY AS CUTTING-OFF MACHINE

Another example of all precedent being thrown aside is illustrated in Fig. 6, which shows a cutting off machine built from a gasoline engine bed and cylinder on somewhat the same lines as the boring machine just described. The hollow spindle extends through the cylinder casting A, being suitably mounted on bearings at each end. The rear end carries the large belt pulley B, while chuck C is mounted on the front end of the spindle. Chuck C is solid, and is bored an easy fit for the rough forgings, which are instantly fastened in position by a blow on the large end of the massive taper pin D. In practice the pin D is stopped in a horizontal position, so as to be conveniently operated by hammer E, which has a head at either end, one for tightening, and one for slackening.

A cross slide is fitted with a tool box F, which carries the tool proper, and is operated by elevating the hand lever G. Shells are received via the chute H, the lowest shell being contained in loader I, which is hinged so as to swing into line in front of the chuck. During this movement the shells in the chute are held back by retainer J. Rod K is used to eject the shell from the loader I into the chuck, the collar on the rod locating the shell. A smart blow or two with the hammer E securely wedges the shell afte which cutting off is merely a matter of belt power and tool strength, both of which are ample, accomplishing the complete operation in an incredibly short space of time.

Each additional shell pushes the preceding one ahead of it until they drop out of the back end of the spindle where a chute with a registering device conveys them to their destination.

Trucks Eliminated

The mention of chutes brings forward what is perhaps the most interesting of the many interesting features in this plant. The duties of the chute system which has been installed here, are passive rather than active, yet its influence on the output in proportion to its cost, is perhaps, greater than any other portion of the plant.

Persons familiar with machine shops, know that a considerable amount of each man's time is spent lifting a job off a truck and putting it back when finished. In the case of shells, this time is apt to be unduly prolonged either through fatigue, or lack of interest, etc. If it is possible to avoid this slackness, and arrange a system whereby the shell is slipped right under the man's hand, where he can reach it without exertion, and which only requires the shell to be lifted to the height of the man's shoulder to start it on the next stage of its journey, then an amount of unproductive energy is conserved, and the time required, which formerly was an actual loss to employer and employee, is now spent in doing productive work, which under the bonus system in force at this factory, means just so much more money for the workman at the end of the pay.

The adoption of the system rendered necessary the establishment of inspection benches at certain points, where the work is received from a preceding group of machines, and is distributed through individual chutes to several machines in another group, which perform the necessary work, and if immediate inspection is required, return it by another series of chutes to the inspection bench. Where corrections have to be made, a "returns" chute is provided to each machine, making three chutes on occasion between inspection bench and each machine of a group.

Should inspection not be required, the operator does not return the shell to the inspection bench, but instead, sends it on by a chute to the machine which is to do the succeeding operation. In this manner the shells travel individually as each stage is completed.

Full advantage has been taken of the many time saving possi-

bilities of such a system, the adoption of which made it possible to immediately locate the cause of any slowing down in production. The whole plant now became one vast unit with each machine, or group of machines, as the case might be, having its output strictly limited to the number of shells sent on to it from the previous group. A choking or overflowing of the chutes indicates where a hold-up is taking place. and enables additional facilities to be provided as the minimum output is shifted around from one operation to another.

A considerable amount of time and labor was also saved by providing each chute with a counter which had suitable symbols marked on it, indicating nature of operation, etc. These counters were simply and cheaply made by using Veeder cyclometers with a large disc mounted on the spindle. The counter is mounted on the chute so that as the shell passes underneath, it revolves the disc a certain amount so that each shell keeps tally for itself. In the case of shells which are returned to a machine for correction, the shell is put in the chute ahead of the counter so as not to register twice.

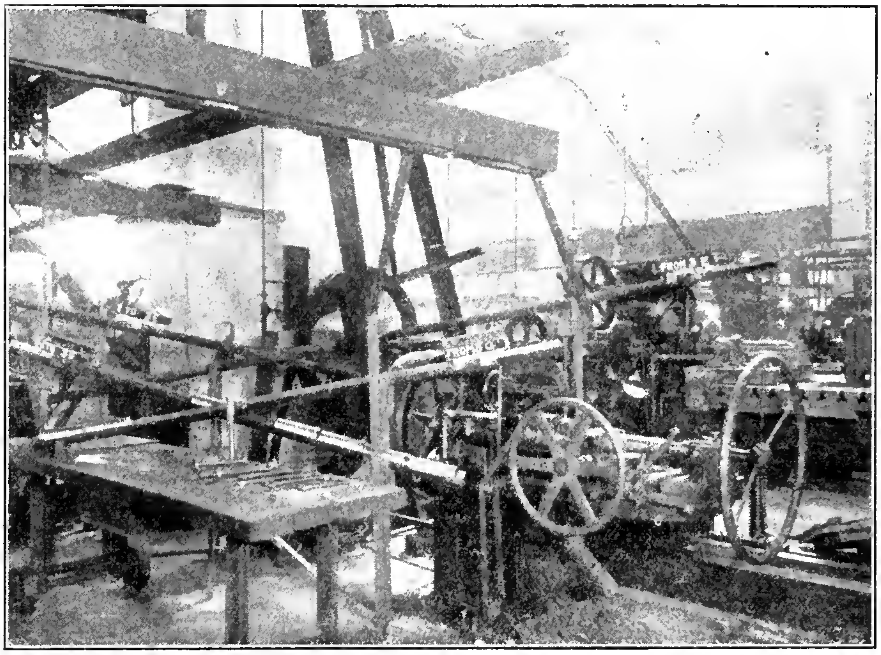

FIG. 7. CHUTE SYSTEM BETWEEN INSPECTION BENCH AND MACHINES.

Fig. 7 shows an inspection bench with chutes serving three boring machines, the small machine in the right foreground being a converted bolt cutter, which has rendered excellent service in shell boring. The counters can be seen on the upper end of each chute at the machines. Fig. 8 gives a good idea of the labor saved in carrying shells from the banding press to the band turning machines. These machines are small turret lathes fitted with automatic collet chuck coupled up by link motion to the turret slide. The movement of the turret tightens the chuck and takes a rough cut off the band at one operation.

Finishing and sizing tools are mounted on small cross slide. With copper of average softness, one of these machines can finish a band complete in 27 seconds.

A great amount of labor in handling, counting and trucking shells is thus dispensed with, and records are kept up to the hour or minute if desired.

Premium and Bonus Systems

The greatly increased output in this plant is largely due to the efforts and ability of the company's executives in providing labor saving devices, improving machining methods, rebuilding machines, developing chute systems, and otherwise keeping up every detail of the work to the last notch of efficiency. Such efforts by the company would have yielded much less gratifying returns had it neglected that all important factor of modern commercial success, i.e., the human element.

Some concerns have attained considerable prominence, and achieved large financial success while maintaining an attitude of decided indifference towards employees' earnings. The possession of valuable patent rights and large profits accruing therefrom have in a few individual instances enabled the employers

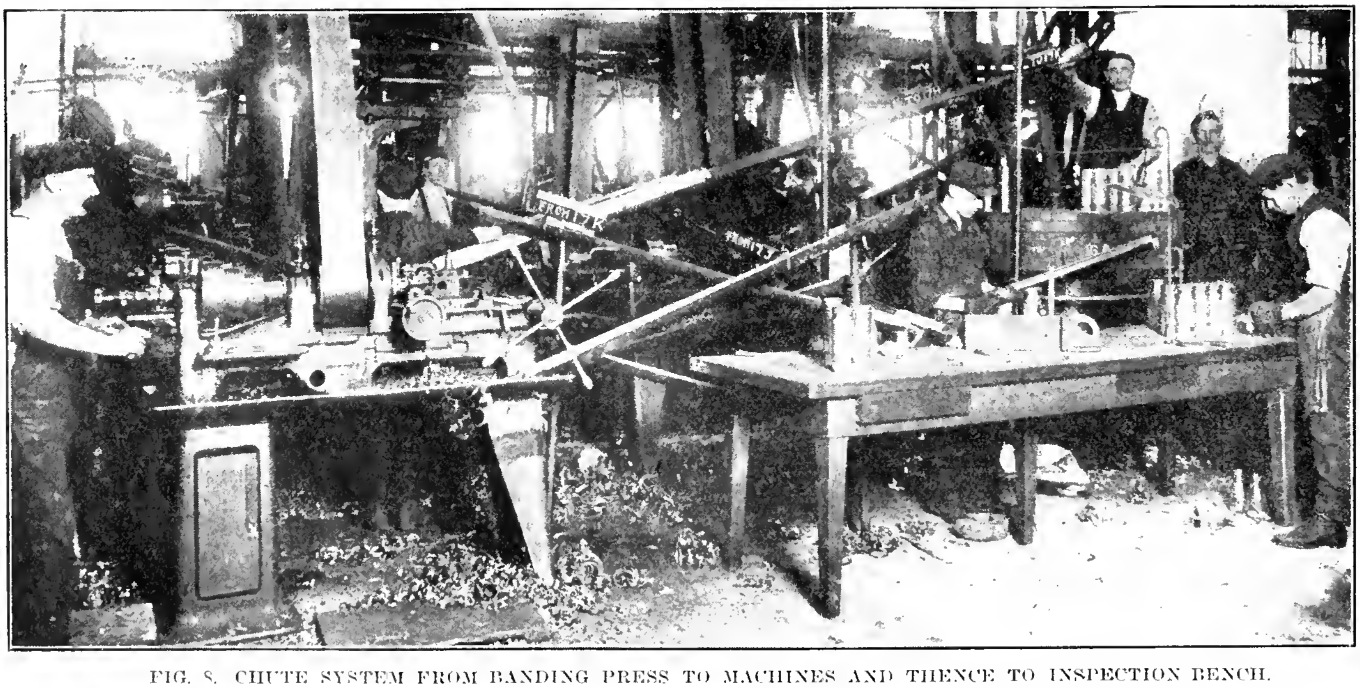

FIG. 8. CHUTE SYSTEM FROM BANDING PRESS TO MACHINES AND THENCE TO INSPECTION BENCH.

to ignore altogether the just claims of the actual producers.

The capable manner in which this concern approached the problem of securing the men's whole-hearted co-operation has met with all the success to which it is entitled. It is safe to say that the attitude and enthusiasm of the men toward the work being done, is only equalled by the sincerity of their regard for the frank, open-handed manner in which the company has dealt with them.

This desirable condition is due to the adoption and faithful carrying out of a combined premium and bonus system. All of the men who are engaged on machining, hardening, loading, etc., or producing in any form, are paid on the premium system. After careful study, a time limit was established for a certain operation, and except when a new method, process, tool, or other improvement is introduced, this limit is never changed. When the fortnightly earnings are made up on the basis of the number of hours worked, each man receives a premium payment equal to the value of half of the time saved over the limits set for the different operations. In this way every producer automatically becomes a partner in the business, the firm supplying machinery, work, material, power, etc., and sharing equally with each employee the profits which are directly due to his own individual effort.

A Factor of Success

The "human element" is always present in such affairs, and however great the success of the present instance, other cases might result in failure if this factor were not properly regarded. The chief point of this regard is a liberal basis for time limits. If a certain time limit yields a satisfactory cost for a certain operation, then the employer should constantly remember the all important fact that every dollar extra which a man earns as premium, also represents a dollar less cost to the company.

In addition to this premium system, a bonus system has been put into effect which applies to all non-productive labor. This covers tool-makers, stock-keepers, laborers, etc., and also the entire office force. This bonus is distributed on a percentage basis, and is based on the average daily output over a fortnightly pay roll period.

A bulletin board in a prominent position is kept posted with the latest output figures and the corresponding bonus, thus maintaining a state of active expectation which reflects itself in a steadily increasing output at less cost to the firm, and accompanied by proportionately higher wages for the men.

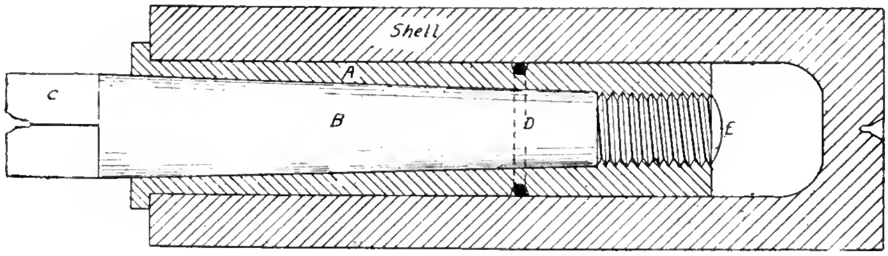
EXPANDING MANDREL FOR TURNING SHELLS

By J. A. Moffat

THE accompanying sketch illustrates an expanding mandrel used in turning shells where the bore is parallel. The sleeve A is turned about .010 smaller than the bore of the shell and is split in the centre to allow it to expand when the taper plug B is screwed in.

A round steel spring D holds the two pieces of the sleeve together. The end C of the plug fits into a square driver fastened to the face-plate of the lathe. The screw E is made standard pitch, which prevents the plug from pulling out when the sleeve expands.

In practice two mandrels are used. While one shell is being turned, its predecessor is being removed from the mandrel and another put in its place and made ready.



EXPANDING MANDREL FOR TURNING SHELLS.

MOLYBDENITE SAMPLES FROM NORTHERN QUE.

G. R. E. KENNEDY, of Sherbrooke, has returned from a trip into Northern Quebec, with some 50 lbs. of molybdenite specimens which have been sent to the Assay office for analysis. They were obtained by him and J. D. Kennedy, who investigated and successfully relocated claims formerly taken up and prospected by Capt. K. E. Kennedy, who had to abandon them on going to the front.

Remarkable rich samples were secured with nothing but a prospector's pick, in a granite and pegmatite formation, of which there is a large area, and covered by their claims.

There are only a few places in Canada where this somewhat rare mineral, molybdenite (sulphite of molybdenum) is found, and the world's production is very limited.

It is used in the manufacture of high speed steels armor plates, rifle and big gun barrels, etc., to which around 10 per cent. imparts the quality of taking a great heat without loss of temper. It is now in great demand by Great Britain and France. Before the war, it was worth around $400 per ton, for 90 per cent. concentrates. Late quotations are $3,300 up. It is substituted for and superior to tungsten.

The Kennedy Claims are splendidly situated for shipping and can be worked to great advantage by tunnel, which, with the fine showing of ore, give the property all the earmarks of a very valuable mine, despite the usual pockety nature of the few known deposits of molybdenum.

STEEL MAKING IN ELECTRIC FURNACES

THE making of steel in electric furnaces was the subject of several interesting addresses given before the Montreal Metallurgical Association at a meeting held on October 13 under the chairmanship of Dr. Alfred Stansfield. Attention was drawn to the fact that the making of steel by this process is about to be practised in Montreal. The meeting was opened by Dr. Stansfield, who spoke of the commercial possibilities of the electric furnace in steel foundries.

The chairman was followed by Mr. Davey, of the Canadian Brake-Shoe Co., who gave a detailed account of the furnaces in use at the Sherbrooke steel foundries of that company. These furnaces are four in number, each of 5,000 pounds metal capacity.

G. C. McKenzie, of Ottawa, representing the Mines Branch of the Department of Mines, told of the electric furnaces for making steel at Welland and Toronto. He referred also to the Moffatt-Irving process for the production of steel directly from Canadian ore, and explained that this process was about to be tested by the Government.

Mr. Evans, of Belleville, described the Evans-Stansfield process for making cold steel electrically from titaniferous magnetite ore.

A short account of steel making at the Longueuil plant of the Armstrong-Whitworth Co., which will shortly introduce the Heroult furnace for that purpose, was given by C. Bristol, and Mr. Green, of the same company, had with him some materials which he melted in the electric furnace in the McGill metallurgical laboratory. At the end of the meeting he poured the molten steel into two ingots .

Sheet Metal Elbows: Their Development and Laying Off

By J. W. Ross

In order to thoroughly understand the principles involved in the development of cylindrical and other forms, such as are met in sheet metal work, a considerable knowledge of geometry is desirable. Through the medium of these articles, the author places practical examples at the disposal of our readers, and the knowledge to be gained by a close and persistent study of the principles and methods employed will well repay the time spent.

THE fabrication of elbows forms a considerable part of sheet iron workers' practice. The various forms, cylindrical, oval and rectangular, will be herewith described, and the patterns developed for both heavy and light plate.

For the purpose of students' home practice, the measurements will be given in inches, so that the developments may be made on stiff paper. The patterns may be perforated at the located "rivet holes," by a punch similar to a tram conductor's transfer punch, which may be purchased at any 15-cent store. this punches a round hole. The patterns can then be connected together by common paper fasteners. This is good practice for the student in laying out the rivet holes, which will give him the necessary confidence when laying out on the plate.

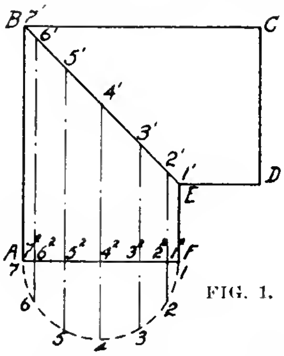


FIG. 1.

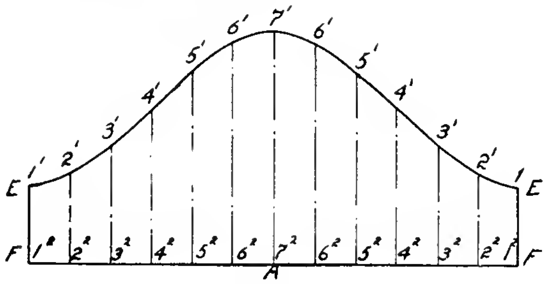

FIG. 2.

Cylindrical Elbows

Fig. 1 shows an ordinary two-piece 90-degree elbow which will be developed by the parallel line method.

Measure off AF, Fig. 1, equal to 1½ inches, at right angles to AF, draw AB and FE, making AB equal to 2¼ inches, and FE ¾ inch. BC is drawn parallel to AF, and equal in length to AB. CD is parallel to BA, and equal in length to AF. DE is drawn at right angles to CD and EF, and of the same length as EF. Connect the mitre line BE, which is at 45 degrees, to the lines BA and BC. Bisect AF, and with 4^2 as centre and 4^2 A as radius, describe the semi-circle A 4F, showing the half section view of the elbow. Divide this view into a suitable number of equal parts, in this case 6 parts are chosen. Each point is numbered in consecutive order. From these points draw lines parallel to the lines AB and EF, up to their insections with the mitre line BE, which are numberged in relation to the points on the half plan view.

As the elbow is made in two courses and of equal diameters, it will readily be seen that the mitre line as stated forms an angle of 45° degrees, therefore it will only be necessary to lay out one course, from which afterwards the other may be marked.

The neutral circumference of the elbow, or the stretchout as it is more generally termed, equals the neutral diameter multiplied by either 3 1/7 or 3.14, which equals $1.5 \times 3.14 = 4.71$ inches, or slightly under 4¾ inches. Measure off FAF, Fig. 2, equal to 4¾ inches. Bisect at 7^2 and erect the perpendicular 7^27^1. Divide 1^2 to 7^2 into the same number of equal spaces, as in Fig. 1 on the plan view; also divide 7^21^2 similarly, thus making 12 spaces in all. Erect perpendiculars on these points, which are, of course, at right angles to the line FAF, and parallel to the centre line AB. Set the dividers to the distance 7^27^1, Fig. 1; transfer this over to the corresponding number in Fig. 2. It will be noted the seam is located on the line 1^21^1, Fig. 1.

Reset the dividers in each case to the distances 6^26^1, 5^25^1, 4^24^1, 3^23^1, 2^22^1, 1^21^1, Fig. 1, and transfer over each distance to its allocated line in Fig. 2.

A smooth even curve drawn through these located points will define the mitre line, which is also the rivet line. Laps are to be added to the rivet mitre line, and also the rivet lines 1^21^1, Fig. 2, for the vertical seam.

As both courses are the same size, the connection at the mitre line, after the plate is rolled up, will necessitate one of the courses to be slightly opened out with a machine suitable for that purpose, or, in default, with a hammer, so that one course will fit over the other.

In tinsmith work suitable seaming allowances are made according to the style of seaming. Fig. 2 shows the pattern without any allowance for laps.

60-Degree Elbow

Fig. 3 shows the elevation and half-sectional views of a two-course cylindrical 60-degree elbow. Draw the line GLO, make OL equal to 1 1/16 inches, and the neutral diameter of the elbow GL equal to 1½ inches. With centre O and radius G, describe the arc GI. With the same radius and G as centre describe another arc to intersect arc GI at I. Connect I to O by a straight line.

The angle formed by GO and IO is 60 degrees. Bisect the arc GI at M, and through this point draw a straight line from O, extending to H. At right angles to GL draw the lines GH and LK to intersect the mitre line HK. Connect H to I and K to J. If carefully constructed the course GHKL will be equal to HIJK. Bisect GL at 4^0 and draw in the half-sectional view G4L. Divide this semi-circle into any number of equal parts, according to the exigencies of the work. Project these located points to the mitre line, as explained in Fig. 1.

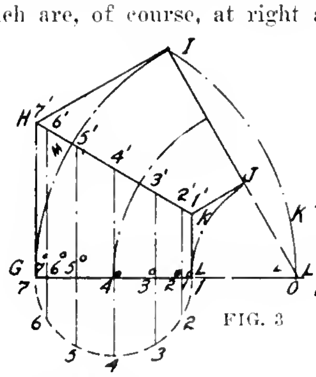

FIG. 3

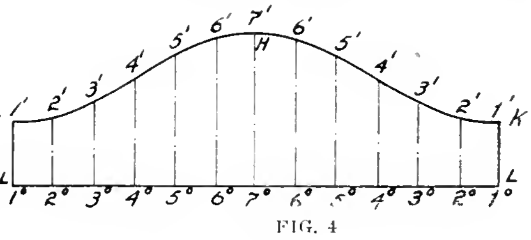

FIG. 4

The stretchout LGL, Fig. 4, equals 1½ times 3.14, which equals 4.71 inches, or slightly less than 4¾ inches. Bisect this line LGL at 7^0 and erect the perpendicular 7^07^1, thus locating the centre line

of the templet, and also defining the seam lines 1^01^1 and 1^01^1. Divide 1^07^0 and 7^07^0 each into the same number of equal spaces, as in Fig. 3. Erect perpendiculars parallel to the centre line 7^07^1 through the points thus located, also numbering each perpendicular in relation to the construction lines, as 1^01^1, 2^02^1, etc., in Fig. 3. Transfer all the distances 7^07^1, 6^06^1, 5^05^1, etc., in Fig. 3, over to their corresponding ordinates in Fig. 4. An even drawn curve through these points locates the rivet line or seaming line. Laps to be added accordingly.

Elbow With Gore

Fig. 5 illustrates a two-course 90-degree elbow, with the section BKC cut away to clear an obstruction, the gore BCH being fitted to the resultant opening. Fig. 9 shows the templet for the gore, and Fig. 6 for each of the courses.

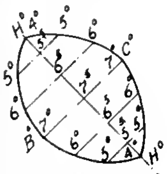

FIG. 9

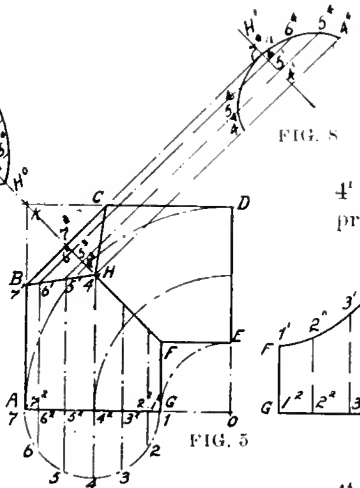

FIG. 8

FIG. 5

Measure off on the line AGO, Fig. 5, AG equal to 1½ inches and GO to ¾-inch. With O as centre and OA as radius, strike the quadrant AD. With OG as radius and O as centre, strike the quadrant GE. Connect D to E, which is in line with O and at right angles to AG. Bisect the quadrant AD, and through this point draw a straight line from O to K, thus locating the mitre line. Draw KA at right angles to AG, and KD parallel to AG. Locate the points B, C by measuring ⅞-inch from the point K. Connect B to C, thus defining the portion cut away.

With 4^2 as centre, draw in the half-sectional view 7, 4, 1. Erect the perpendicular 4^24^1 on the line AG. The point H where the line intersects the mitre line KF will also locate the termination of the gore. Connect B to H and H to C, which makes BH and CH the mitre lines between the gore and the courses. Divide the half-sectional view into a number of suitable equal spaces, as shown. Project the points 6 and 5 to their intersection with BH, also the points 3 and 2 to the mitre line HF.

The stretchout GAG, Fig. 6, equals 3.14 times the neutral diameter 7 1, which equals $3.14 \times 1\frac{1}{2}$ = slightly less than 4¾ inches.

Measure off GAG, Fig. 6, equal to 4¾ inches. Divide this into 12 equal spaces, erect perpendiculars and number in relation to their corresponding lines in Fig. 5. Set the dividers to the various distances, 7^27^1, 6^26^1, 5^25^1, 4^24^1, 3^23^1, 2^22^1, 1^21^1, in Fig. 5, and transfer these over to their allocated lines on Fig. 6. An evenly-drawn curve through these points locates the mitre or rivet line. Fig. 6 illustrates the templet, to which must be added laps according to requirements, whether for seaming or riveting.

The gore BCH will now be dealt with. It is here necessary to have a cross sectional view through the plane $H7^3$, Fig. 5, to obtain the true length or stretchout of the gore, which is foreshortened in the elevation view shown in Fig. 5.

The cross sectional view is shown in Fig. 8.

The construction of such is as follows: From the points 7^1, 6^1, 5^1, 4^1 draw parallel lines to BC, and project to the points 7^4, 6^4, 5^4,

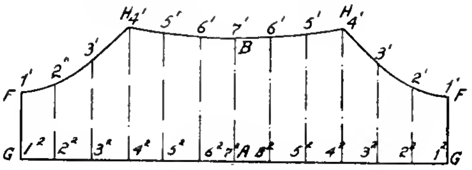

FIG. 6

4^4, Fig. 8. Draw in the line H^1F^1 parallel to KH, and right angles to the projection lines, 7^17^4, 6^16^4, etc. Now with distance equal 4^24 in plan view, Fig. 5, measure off the distances 4.4^4 in Fig. 8. Similarly with distances 5^25 and 6^26, Fig. 5, transfer to $5{,}5^4$ and $6{,}6^4$, Fig. 8. Draw an even curve through these points. This shows the true length of the gore through 7^3H, Fig. 5. The mitre line FK is extended to H^0H^0. On this is laid off the true length of the gore which has just been computed.

The exact length of the distances 7^4 to 6^4, 6^1 to 5^4, and 5^4 to 4^4, measured along the curve, is transferred to Fig. 9, as 7^5 to 6^5, 6^5 to 5^5, and 5^5 to 4^0. Lines are drawn through these points at right angles to the line H^0H^0. The distances on the gore BCH, 7^37^1, 6^36^1, and 5^35^1, Fig. 5, are transferred and measured in Fig. 9, as 7^57^0, 6^56^0, 5^55^0. A curve drawn through these points completes the pattern, with the exception of the laps. This curve locates the rivet lines, and all the points of intersection on the templets, Figs. 6 and 9, may be used for the pitch of the rivet centres through which the holes may be punched—by the punch already referred to, so as to facilitate the fitting up of the paper models—and in the case of plates for riveting together by.

TEMPERING REAMERS AND TAPS

A GOOD way to harden a long reamer without warping is to suspend the reamer and tongs by a twisted string. When the reamer is heated properly, hold it over the tub perpendicularly by the string in one hand, and keep it from turning with the other. When ready let go and allow it to revolve rapidly and dip at the same instant. Reamers or taps hardened in this way will remain straight. This idea is worth testing, not with a bit of twisted string, but with a proper mechanical rotor, the speed of which could be varied in the experiments. There are many small cutting tools which cannot be hardened and kept to their required form. A good many twist drills are not very straight after tempering.—Ex.

PREVENTING CORROSION IN BOILERS

IT IS extremely doubtful whether the suspension of zinc slabs in a boiler will prevent scale, says the Electrical World. Scale is due to the presence in the feed water of substances like the sulphates and carbonates of lime and magnesia. When the water is heated, these substances are precipitated and are baked on the plates and tubes. The action of zinc in a boiler is galvanic and is intended primarily to prevent corrosion of the metal parts of the boiler. To prevent scale formation, it would have to change the nature of the sulphates and carbonates or else keep them from coming in contact with the boiler, neither of which it is able to do.

It is true that in the course of the galvanic action set up by the use of zinc, hydrogen is set free at the water surface of the plates and tubes, and the liberation of hydrogen in this way, if rapid enough, might prevent scale from adhering; but it is scarcely to be believed that the feeble galvanic action set up by the use of zinc slabs could produce hydrogen at a sufficient rate to keep all sediment and precipitates from collecting on the surfaces on the metal.

Steel Piston Rod Tests.—An American steel concern has announced the results of a series of tests on piston rods made of the steel it manufactures. The steel showed a tensile strength of 123,775 lbs. per square inch, an elastic limit of 82,600 lbs., with an elongation of 24 per cent. in 2 in., and a reduction of area of 53 per cent. In a revolution testing machine, 984,933 revolutions were required to break the test pieces at a stress of 30,000 lb. per square inch. This steel, which contains manganese, is produced in an electric furnace.

Papers Read at the Recent Foundrymen's Convention

Selected from the more important subjects presented for discussion before the Annual Convention of the American Foundrymen's Association and the American Institute of Metals at Atlantic City, N.J., during September, 1915. The papers cover a wide field of foundry and allied activity, the nature of the results and the completeness of the reports making them of particular interest to all who desire to keep in touch with metallurgical progress.

THE CONVERTER IN STEEL CASTINGS MANUFACTURE

By C. S. Koch*

A WRITER of a paper on the manufacture of steel castings, some four or five years ago, started with the following words: "This subject has already been discussed so thoroughly before this association, that not many points remain uncovered." Since then there have been numerous additional papers. Consequently, it has been difficult for the writer to dig up something not yet touched upon, which would still be of general interest. There have been refinements in many ways, but they are generally too detailed to go into. If one looks over the Transactions of the Association, he will find a large amount of good matter on the converter. He will find papers on its construction, its lining, its manipulation, and its chemistry, and all the details pertaining thereto, all of which is of interest to those who are in close touch with the subject. However, little is found in regard to the various factors which have tended to make the converter a successful means for making steel in many cases and equally as disastrous in as many more; little material is available giving reasons why the converter is still being run in some foundries after 10 or 15 years, and why it was run six months or less in others. The writer proposes to discuss this subject.

Is the Converter Practical?

If, say 10 or 12 years ago, the following question were asked, "Is the converter a practical means for making steel for castings?", the total number of replies in the affirmative would have been less than 10. That is, replies from men whose experience would justify their endeavoring to answer the question. The number of negative replies would have been almost too great to record. The proportion would have been about nine negatives out of 10 answers. If the same question were asked to-day from the same class of individuals, the trend of replies would be just about the reverse. The converter process has about as large a proportion of adherents to-day as it had adverse critics 10 years ago.

Up until about 1905, the failures greatly exceeded the successes. For the next five years, the number each way was nearly equally divided and of late years, the successes have been, probably, in excess of the failures. But we must not lose sight of the fact that news of a success is published, while that of a failure is squelched. In the early days, the failures were not due, as we might suppose, to the crudity of the process, but rather, as a rule, to the fact that in a great number of cases the converter was being employed for purposes for which it was not adapted and was being wrongly applied. Better results have been obtained in recent years because the users have exhibited better judgment in the selection of the particular lines into which they have entered.

This can be demonstrated by an analysis of the history of the converter foundries of the United States. In making this analysis, trade conditions must be taken into consideration as they vary from one locality to another.

The conclusions from this examination seem to show that the following statements are approximately true:

1.—The application of the converter to the manufacture of a general line of railroad car castings has not, to date, been a success.

2.—The use of the converter in conjunction with an open-hearth furnace has not generally met with success. That is, the open-hearth foundries, which have endeavored to add the converter to their equipment, have nearly always given up this process after a short trial.

3.—Iron foundries which have endeavored to add the converter to their equipment, except in favored conditions, have been unsuccessful.

4.—Various manufacturing companies, having a fair consumption of steel castings, have not by any means been satisfied with the results of making a small tonnage for their own use.

Why Success Was Achieved

On the other hand, the resume of the history will show the companies that have been successful, and in almost every case it will be found that these companies have employed the following methods:

1.—They have made steel by no other process.

2.—They have adhered, as a rule, to a maximum metal line, or perhaps, we might say, weight of casting. This weight has varied somewhat in different localities, as competition and a few other conditions have varied.

Now all these causes for failure and success can be argued pro and con and exceptions can be cited. Nevertheless, if anyone is considering the application of the converter to the steel foundry business, he would do well to give due weight to the foregoing, because the statements given are not the result of theoretical considerations, but of a detailed analysis of the history of the converter business for the past 15 years.

It will be noted that in the writer's opinion, the reason for successful operation has been careful consideration of the maximum weight and the question naturally arises, what is this? It will vary in different localities, but is more or less dependent on the proximity, activity and attitude of open-hearth steel foundries.

Generally speaking, converter steel costs more than open-hearth steel. Consequently other things being equal, such plants can underbid the converter plant on all such castings as they can properly run. Therefore, if a converter foundry is in a locality where open-hearth competition is keen, the maximum weight of the castings which it ordinarily can take at a profit will be less than in the case where such competition is remote or less active. In considering this competition, there is another element that should not be overlooked. The manufacturer of large, heavy castings naturally has a lower average overhead per ton, and unfortunately in many cases, this small overhead expense is spread equally over the large and small work. In bidding, this naturally puts the converter plant at a disadvantage, with the logical tendency of restricting the converter plant to castings which the open-hearth cannot run; that is, restricting it to smaller and smaller castings.

Effect of Increased Skill in Molding

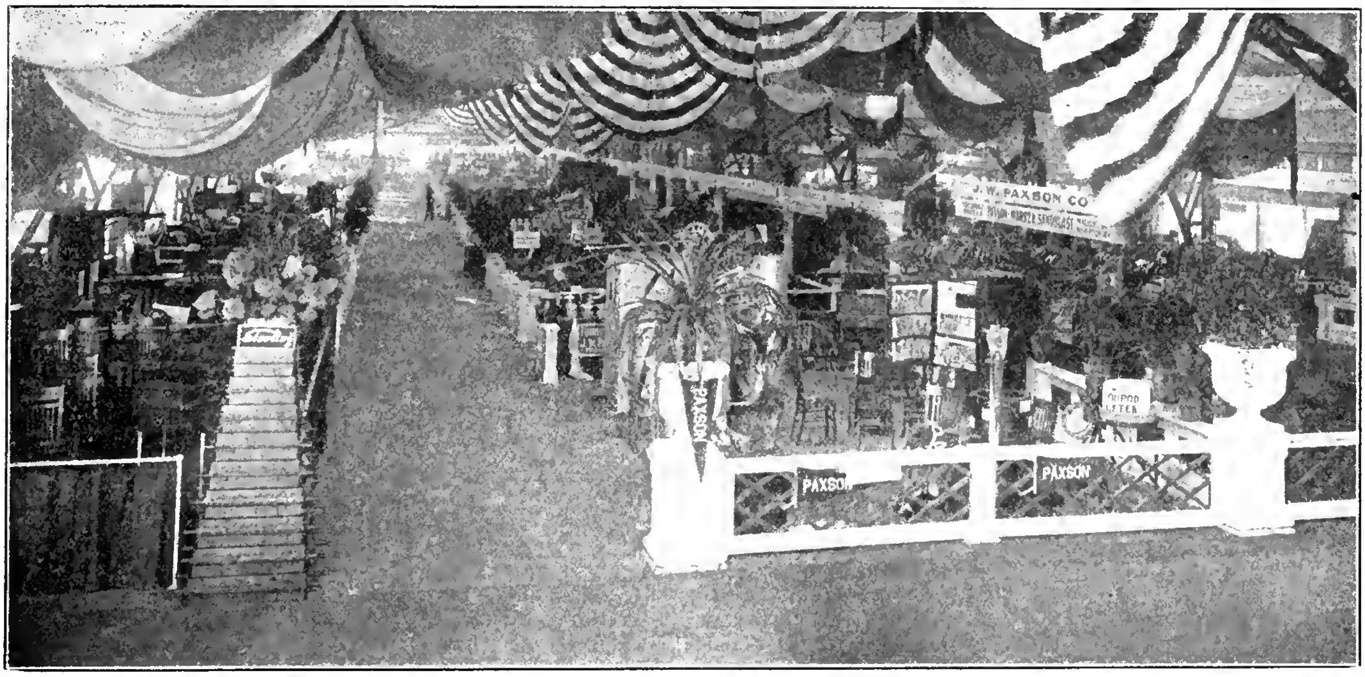
Again, the tendency in some localities is for the manufacturers of large castings to encroach more and more on the field of the converter shop owing to increased skill in molding. It is believed by the writer that owing to various conditions, greater skill in molding difficult, medium-size castings was formerly possessed by the converter plant. During every dull period, in their desire for work, the manufacturers of large castings have gone after more difficult jobs. This has developed their skill and given them confidence.

We have already stated that in the past, success was more or less dependent on restrictions to small work, and these latter considerations show that in the

*Fort Pitt Steel Casting Co., McKeesport, Pa.

future the converter plant will be compelled to carry this restriction further. There are, however, modifying features that should be given weight. There are converter plants strewn all over the country, located in districts where ordinary competition from the cheaper metal does not exist. These reap profits not possible to others. For example, the plant may be at such a distance from outside competition that the buyer is willing to pay a price sufficiently high to enable the converter plant to take the work with a reasonable profit. Proximity to user is always a valuable feature.

Most all conveiter plants, even the successful ones, handle some large work. This is obtained on the basis outlined previously, but it would not be safe to bank too much on this as being a particularly lucrative part of your business. From all of the foregoing it must not be concluded that the amount of work to be done by a converter plant is to grow less. On the contrary, new uses for steel are being found, which will give the industry more work than formerly. It is an adjustment of classes that will follow.

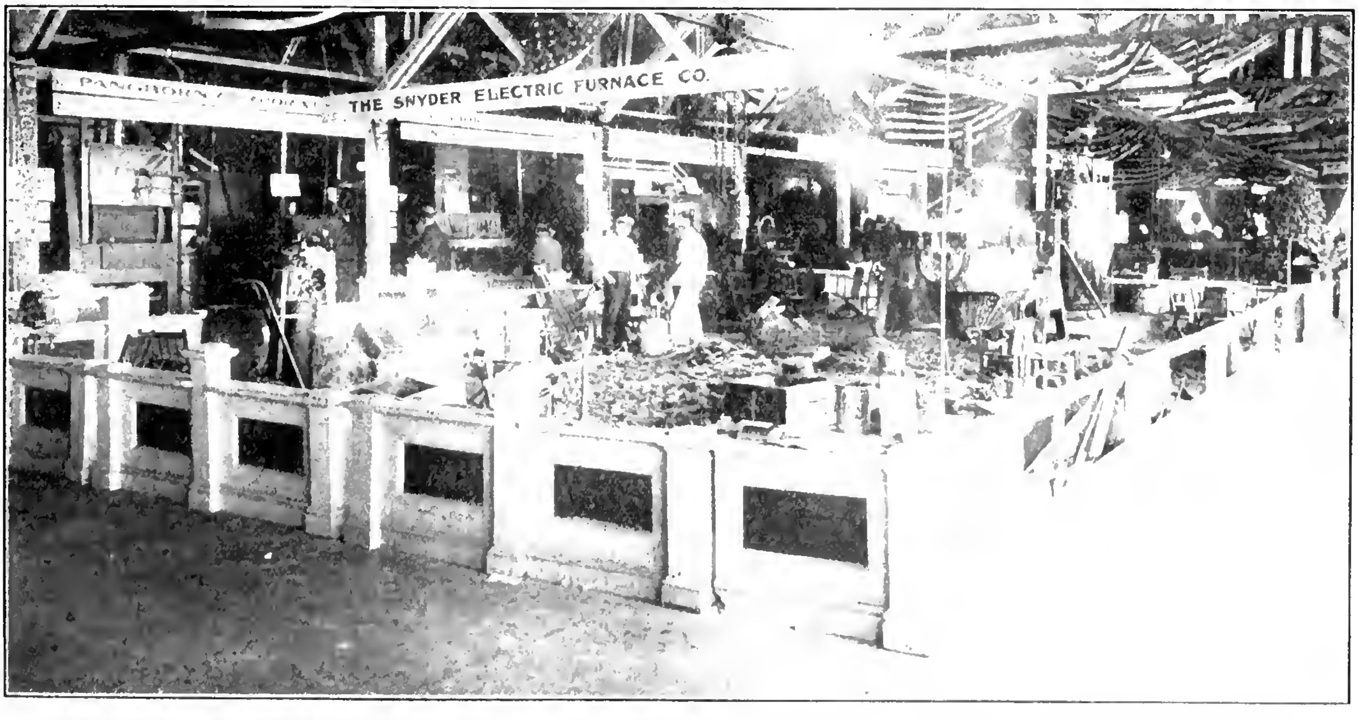


GENERAL VIEW IN ANNEX, FOUNDRY AND MACHINE CO. EXHIBITION, ATLANTIC CITY, N.J.

Shop Practice

To return more particularly to the application of the converter, there are a few fundamental principles of operation that it may be well to mention. These, again, are not theoretical considerations, but are brought to mind by a study of what has been accomplished and **not accomplished** by the converter plants of this country:

The points I wish to make are as follows:



MACHINERY HALL EXTENSION, FROM LOWER END, FOUNDRY AND MACHINE CO. EXHIBITION, ATLANTIC CITY, N.J.

1.—Unusually good cupola practice is essential.

2.—The speed of the cupola should be regulated to the speed of the converter, that is, neither too slow nor too fast.

3.—Proper crane facilities are necessary.

The writer has endeavored to learn the causes, (a) of complete failures, (b) of the cases in which there was perhaps no real failure, but in which there was a discontinuance in the use of the converter, and (c) of mediocre success. As far as the steel-making end was concerned, these could be attributed to a bad combination of the three operations listed.

Holding the cupola back in any way whatever, to wait for the crane or the converter is not good practice, especially when the economical operation of the converter requires the use of a burden of perhaps 40 per cent. steel scrap. It should not be necessary to say much on this subject to foundrymen, but strange to say many converter foundries can be adversely criticized on this point. Quality and temperature of iron should be considered and if a large number of heats are to be taken off, the time element is essential. As is well known, a 2-ton converter will produce steel at the rate of two tons every 20 to 25 minutes. If 12 heats are produced daily, an unnecessary delay of only five minutes per heat will aggregate one hour. It is well not to be obliged to start pouring any earlier in the day than is necessary on account of fumes and heat, but at the end of the day overtime is not only costly, but has many other disadvantages. Consequently, quick operation, at a uniform rate, is helpful, and this can be obtained only by a well-run cupola that is not too slow for the converter, and by proper crane facilities, arranged to remove the steel from the converter as soon as it is blown and to immediately refill the converter with iron. The crane should not be busy pouring off, when it is wanted at the converter. A wait means holding back the cupola, which means not only loss in time, but bad iron later in the day. That the ideal relationship of cupola, converter and crane is not present in many foundries is not the fault of the foreman or superintendent, but is due to original faulty design.

Temperature of the Steel

Furthermore, the temperature of steel should be uniform from heat to heat and should be adapted to the class of work turned out and arrangement of the shop. The need of some shops is for steel much hotter than others. This is logical and correct and one might say that each shop has its own particular ideal temperature. This should not be higher than necessary, as heat is costly. Most shops do not seem to aim at any particular temperature. The result is changed temperature conditions daily. This puts the foreman at a disadvantage in guiding his molding practice.

If the ideal shop temperature is eventually attained, there still remains a difficulty. The steel will be too hot for some castings and too cold for others, and will burn in badly on some and not run others. To avoid this and many other foundry difficulties, the policy of the company should be toward a narrow range of sizes. It will be argued that this cannot be done in a jobbing shop, which must take whatever comes. The only answer to this is that such a statement is like many others emanating from foundrymen. We are in a rut and not until we get out, and break away from antiquated, preconceived principles, will we attain the highest degree of success. Establish your class and range of sizes and adhere to it. You will loose some work to the other fellow and at the same time take some from him. In time your plant will be operating on work for which it is best adapted, and your competitor will be doing likewise. You will have made the first step in specialization. In conclusion, let me say that the first step to take in the practical application of the converter to the steel foundry is to specialize, being sure that it is on that class of work to which the converter is best adapted.

GRAY IRON CASTINGS DEFECTS—THEIR CAUSES AND REMEDIES

By Herbert M. Ramp*

A COMPREHENSIVE discussion of the causes of defects common to gray iron castings and remedies for overcoming them would encompass the consideration of practically every foundry operation, but unfortunately the time at our disposal will permit only of a brief review of this interesting and complex problem. A discussion of the losses incurred by defective castings is one of the first things a man hears when he enters a foundry and it usually is the last thing that comes to his notice when he leaves it. Unfortunately, more attention is given to the losses incurred by defective castings than to making improvements that will eliminate practices that cause them. More consideration is given the pounds of bad castings a molder produces than to his output of good work. Also, more importance is attached to the bad castings reported than to the cost of productive labor per ton. The reason for this is not hard to find. The one is a tangible, direct loss that stares the foundryman in the face every day, while the others are intangible factors that can be corrected by the exercise of gray matter and the installation of proper equipment.

It is estimated that defects common to gray iron castings are the direct cause of the rejection, or loss, of at least 5 per cent. of the iron castings produced. Some patterns may have a better record, although many, also, will show a higher percentage of loss. This estimate on the average, however, is low. If this loss were eliminated many foundries struggling for existence today could not make a profit on their operations. The reduction of the defective output is a problem of great importance and should command the earnest attention of every foundryman.

Ninety per cent. of all defects can be attributed to two causes, namely, incompetency and carelessness. However, since it is exceedingly difficult to obtain competent and careful labor, the operations involved in making castings to-day must be so safeguarded and simplified that a lesser degree of experience, intelligence and care is necessary to the successful operation of the casting plant than heretofore. Classifying casting losses in the order of their causes, it will be found that 50 per cent. can be attributed to the sand and its treatment, 20 per cent. to the cores, 10 per cent. to the patterns, five per cent. to equipment and five per cent. to the iron.

What constitutes defects in gray iron castings is another question of great importance. The standard of excellence for the different classes of castings varies and consumers using castings of a similar nature for the same purpose, frequently will have widely varying requirements. In other words, castings that will be accepted by one company will be rejected by another, and the line differentiating sound from defective castings is drawn at different points. In this respect every consumer is a law unto himself, and there really is no standard for casting quality. Each consumer fixes what he considers a standard for his own requirements which he believes is adequate to his needs.

Sand as a Cause for Defectives

No effort will be made to enumerate the many causes leading to the production of defective castings as the list will be entirely too long and, furthermore, in many instances the causes are so obvious that further comment is unnecessary. However, some practices are common to many shops which cause needless expense, and these are repeated day after day in one form or another without an intelligent effort being made to correct them. The sand, and its treatment, is probably one of the most prolific causes of defects, and to it can be attributed more losses than to all other causes combined. In three cases out of four, the sand is the cause of dirty castings: it causes the mold to cut and the castings to scab and blow. If a casting blows, it is generally attributed to the cores, the

*Elmwood Casting Co., Cincinnati, Ohio.

sand or its treatment, and its repetition is guarded against. However, the cause of the cut, scab or buckle is not investigated carefully, notwithstanding the fact that the losses thereby incurred are deadly to profits. It is the small defect that causes the foundryman to stop and wonder if the casting will pass the machine shop, but finally after it has been cleaned and shipped, it is returned with a caustic letter of complaint. It might be pointed out in this connection that the little foxes spoil the grapes. A casting that is defective beyond question usually points out its own remedy, but the casting which is questionably defective is the most elusive. The remedy is not sought as earnestly or intelligently as that causing the larger defect, neither discovers a scabbed casting, he usually tells the molder to be more careful, or advises him that the mold was too hard or too wet, or whatever his judgment dictates, but how often does he examine the facing and the sand? How often does he employ every possible resource to secure better sand or to make mixtures of sand for his work that are more satisfactory? How often does the foundryman show the molder how to ram the mold, to vent or finish it? How many foremen to-day believe that they discharge their duty by merely telling the men in their employ what is patent to any one who has walked through a foundry a few times in place of personally instructing them how to avoid their troubles and to do their work right? tion of the supervising force. The molder next must be instructed in its use and if defects develop in his work, he must be taught, regardless of the fact that he may have pounded sand for 40 years. It is futile to attempt to formulate fixed rules covering supervision and instruction, since every foundryman has individual ideas on this subject. However, not many realize that the cause of defective castings might be eliminated if they would start at the sand bin and see to it that the best possible sand is obtained and that the proper instructions are given regarding its use. Too frequently, also, this instruction partakes of the form of criticism, when the molder is called to the scrap pile where his defective castings

MACHINERY HALL, LOWER END, FOUNDRY AND MACHINE CO. EXHIBITION, ATLANTIC CITY, N.J.

are the molders instructed as carefully to prevent the causes of small defects as of those which are more apparent.

The foundryman usually becomes provoked and exceedingly angry when a molder has a run-out or breaks a casting hot. He views this in the light of exceedingly poor workmanship, but he considers in an entirely different spirit a casting that is slightly scabbed or dirty. The casting that is almost good enough offers the most difficult problem and the cause of its defect, as a rule, cannot be determined readily.

Scabs, Cuts and Buckles

Scabs, cuts and buckles come and go. They vary with the temperament of the man who wields the rammer and the vent wire and blossom forth with the use of too much water, too much finishing, too little venting and the use of improper sand. When the foundryman

Poor or misused sand is the cause of more defective castings than any other factor. It has a decided influence on the cost of the product and may be the means of establishing a reputation for high grade or poor castings. It is the foundation upon which the entire foundry structure is built. Suitable sand means better and cheaper castings, lower losses and an easier shop to operate successfully. It is one of the great fundamentals of a happy business.

Preparation and Use of the Sand

Next in importance are the instructions regarding the preparations and use of the sand after its careful selection, consistent with its cost. However, cheap sand frequently is the most expensive raw material that a foundry can buy. The sand must be mixed and tempered for the particular work for which it is required and this must have the atten-

are pointed out to him in no uncertain terms. In other words, in most instances, what should be well-intended instruction, is mere denunciation. Anyone can find fault, but a man must study his business if he wants to place himself in a position where he may be able to correct bad practice. The average molder does not lose a casting on purpose. He feels regretful over its failure, but the average molder does not always know the underlying cause of defects, nor how they may be overcome. He needs help, not hell, which he usually receives. He must be taught the rudiments of the business over and over again, since the conditions of the trade are changing constantly. This is the remedy that must be applied by the supervising force before the defective losses can be reduced. If the same energy is expended in instruction as in

condemnation, far more satisfactory results will be achieved.

Dirt Another Cause of Defects

Dirt ranks as the second of the prolific causes of defective castings. From a molding standpoint, the casting may be perfect, yet it is dirty in the rough, or it may display dirt spots in the finishing operations. The number of excuses attributed as the causes for dirty castings is legion, yet only two can be assigned for this defect. Either the iron does not lie quiet in the mold, or against the cores, or dirt has been permitted to enter the mold with the iron, or it was in the mold at the time when the metal was poured. Occasionally the blacking may wash; again the gates will cut, but more often the dirt can be attributed to the same cause as that of the scab or buckle, namely, improper sand, or its improper treatment. A casting will not be clean when the iron does not lie quietly in the mold. The metal may not boil or agitate sufficiently to cause a scab, yet its effect is apparent on the finished casting. If the slag which accumulates on top of the iron is permitted to enter the mold, the casting, of course, will be dirty and this is true also if the gates cut or scab, or if the gates or runners are improperly constructed, or are defective in any way. It is possible to make a perfect mold, yet if the gates are improperly made, the casting will be dirty and will prove defective. Here again the remedy is care and supervision.

Sources of Dirt

An excuse generally offered for defectives is dirty iron. This is the bulwark behind which the molder hides and is the shield which he employs to cover his shortcomings. First of all, it might be well to direct attention to the fact that iron and dirt are enemies and have nothing in common. The dirt referred to is the foreign substance that occurs or forms on the upper side of finished castings. Iron and dirt have no affinity and are of widely different specific gravities. Ninety per cent. of the so-called dirt in castings is composed of silica, alumina and magnesia and none of these is mixed with iron mechanically. They will not remain in solution by any known process, but they may unite to some extent chemically, in this event changing the chemical composition of the iron. This, of course, could be readily determined. However, the natures of these elements are not similar, repelling each other, which is indicated when such substance rises to the surface of the metal in the ladle. Some of the different oxides contain iron, being formed while the iron is in a liquid state and subjected to the action of the oxygen in the air. These oxides also are classed as dirt. However, this dirt, the same as any other refuse that rises to the surface of the metal in the ladle, must be skimmed-off before pouring and does not form a part of the iron. Oxides cannot, form, however, after the casting is poured.

Dirty Iron.

Iron is unlike most of the non-ferrous metals, in that it will form only a comparatively few combinations with the exception of those produced in the blast furnace. It repels all but a few elements that are taken up in almost constant proportions and these only at extreme temperatures. Regardless of the composition or the character of the iron, if it is melted and poured fairly hot, it will be clean. The sulphur may be 0.05 or 0.20 per cent. the manganese may be 0.20 or 2 per cent., the phosphorus may be 0.10 or 1.25 per cent., but none of these varying contents of these elements will make iron dirty in the castings. The iron may be too hard, too soft, too open; it may shrink, crack, draw or warp, but dirt is not its inheritance, nor its progeny.

During the past 25 years, the author has had direct charge of the mixing and melting of more than 500,000 tons of iron, but he has yet to find dirty iron in the sense assigned for it by the molder. Why does a molder make nine castings good and one bad? Why does a molder make a clean record for 30 days and then lose everything he makes? If a molder can produce 20 good castings why is he unable to make 21 or 200? These are the questions put up to the foundryman every day and he has yet to give a convincing answer. First of all, there are no standards or set regulations governing foundry work. The sand may be wet down more one day than another and this makes different the ramming, venting and finishing problem if the castings are to be good. The iron may be colder and duller one day than another, and this would necessitate the use of gates of different size, or different pouring arrangements and the cores may be swelled out of shape, which would require different methods of securing. The flasks may be worn out and finally give way and a hundred other conditions may arise which never are the same on subsequent days.

Inexplicable Foundry Problems

Little has been done in most shops to remove the many causes of defective castings, except in foundries specializing in a particular class of work. No effort has been made to catalog the ills of the foundry and no one has attempted to place the foundry business on a level with the machine shop. If this were done, many and marvelous changes would be made. The patterns, core boxes and flasks would be inspected daily, the sand would be prepared by machinery and the different grades and ingredients would be carefully measured; different rules would be laid down covering the pouring temperature of the metal, as well as the methods of gating. The foundryman would have a voice in the design of the patterns and he also would have the patterns made, not the cheapest way, but the most satisfactory way for foundry use. Every possible pattern would be mounted on a molding machine instead of placing so much dependence upon the skill of the individual operator. Either by lectures, by a school course, or through technical papers, would be imparted to the molders the knowledge gleaned by the employers as the result of the development of the business. Premiums would be paid for high grade service and efficiency.

The foregoing and many more factors would contribute as remedies for defective casting losses. Unfortunately, these needs cost money and the trail has to be blazed; some must be pioneers in elevating foundry practice to a class where definite standards exist and where definite practice will produce definite results.

The Personal Equation

In a large measure the personal equation will have to be limited and particular jobs will have to be so safeguarded that if Tom Jones lays off a day, his substitute won't make 50 per cent. scrap; that if Mike Murphy has been out the night before, he won't spoil his day's work; or, if a molder has sickness at home, he won't forget some minor detail and ruin his casting. More of the responsibility, judgment and skill must be taken away from the individual and the work must be placed upon a higher mechanical basis than it is to-day. Then, only, will the beginning be made for the elimination of defects in castings. An honest comparison of the defective work of the ordinary jobbing foundry with that of the shop equipped for a special line of work, proves conclusively that defectives can be reduced by placing operations on a higher mechanical plane.

Tellurium belongs to the same chemical group as sulphur and selenium, but unlike these two elements, tellurium is a metal, and resembles antimony in a general way. Tellurium fuses at 500 deg. Cent. and when heated above this point it burns with a fine blue flame to tellurium dioxide, at the same time evolving a very peculiar odor. Its combination with hydrogen forms the very poisonous and colorless gas hydrogen telluride.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

SELF-CONTAINED GRINDING MACHINE

THE grinding machine illustrated herewith is driven by a direct connected motor located towards the rear on the left side. The motor is within the working space of the machine, and as all speed changes are controlled within the unit, it thus possesses the unique feature of being self-contained, no external belting or other driving devices being necessary.

In accordance with the maker's established practice, the grinding wheel travels, while the work revolves in a stationary position. It is claimed that this arrangement reduces the power necessary to operate the machine, much of which would otherwise be absorbed in moving considerable weight instead of doing useful work.

The swivel table has two scales, graduated in degrees, and also in inches per foot. The speed changes for the work are made by shifting a belt on cone pulleys, the mechanism for which is operated by a single lever.

The grinding wheel head is massive and rigid and is mounted to slide on a large V and a flat guide. The spindle, which is of special steel, runs in adjustable bronze bearings, while the driving belt is maintained at a uniform tension by an automatic tightener.

Grinding wheel feed is automatic or hand, the automatic feed varying from .00025 in. to .007 in. at each reversal of the wheel carriage.

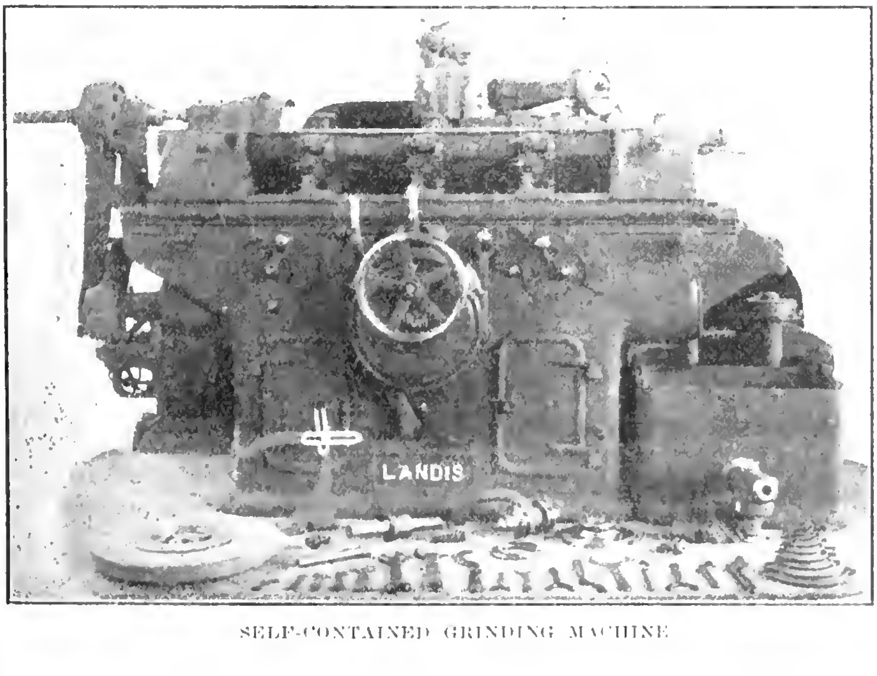
The traverse of grinding wheel is automatic, the movement of a single lever controlling all the speeds by means of a belt on cone pulleys. A period of dwell or tarry which can be varied to suit the work is arranged to take place at the reversing points. Two-point rests with independent adjustment and stops for each support, are provided.

FIG. 1—FLEXIBLE STEEL AIR COMPRESSOR VALVES

The machine is liberally proportioned having a 5-inch driving belt, and 20-inch diameter grinding wheels of 1½ in. and 2½ in. face. Power required is 12 horse power; floor space 8 ft. x 5 ft. net weight 7,800 lbs., boxed for export 9,500 lbs.

When driven from line shaft, an auxiliary shaft with tight and loose pulley, 12 in. diameter, running at 450 r.p.m., is furnished.

The Landis Tool Co., Waynesboro, Pa., who are the makers of this machine, supply a complete outfit of accessories as part of the regular machine equipment.



SELF-CONTAINED GRINDING MACHINE

HIGH SPEED VERTICAL AIR COMPRESSOR

A LINE of air compressors of the high-speed, vertical type exclusively, is being marketed by the Gardner Governor Co., Quincy, Ill. The Gardner-Rix compressors are specially designed to give satisfaction where skilled attention is not always available, and toward this end the mechanism has been simplified to the greatest possible extent.

Light sheet steel valves (see fig.1) are employed. These are flat rings of flexible sheet steel, noiseless in operation, and subject to practically no wear after long periods of service. The valve areas are large insuring economical working.

Enclosed crank cases with splash lubrication are a feature of all the types of these compressors, while the absence of stuffing boxes and crossheads, and the reduced weight of working parts enables higher speeds to be adopted whereby the capacity of machines having cylinders of certain size can be increased. This allows the use of high speed motors on combination units, without having to use gear reductions of excessive ratio.

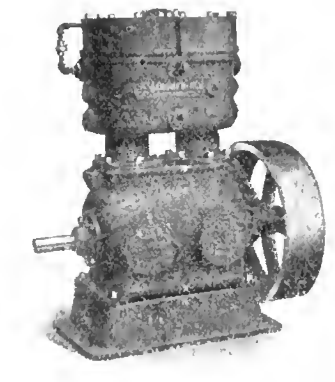


FIG. 2.—CLASS "H" COMPRESSOR

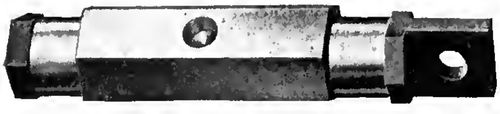
Duplex cylinder compressor with sub base is shown in Fig. 2. Gasoline driven sets, portable outfits with tanks etc., for all classes of work are furnished by the makers, having capacities from 8 cu. ft. to 140 cub. ft. per min. at pressures from 75 to 250 lbs. per sq. in. Cylinder dimensions are from 3 in. bore x 3½ in. stroke to 8 in. bore x 6 in. stroke, weights vary from 165 to 1800 lbs.

PNEUMATIC VIBRATOR

AMONG recent products of the Malleable Iron Fittings Company of Branford, Conn., the "Branford" vibrator is prominent. This device is made in all sizes from ¾ inch to 2 inch. It is an

instant starter and possesses the unusual feature of having all parts hardened and ground, which justify claims



"BRANFORD" VIBRATOR

to long life, economy in air consumption, and ample power capacity.

The makers guarantee this apparatus against defective workmanship or material.

FUEL OIL HEATER AND STARTER.

THE use of liquid fuel for steam generating purposes, etc., is becoming more common every day, especially near the large oil fields. In burning crude petroleum, the fuel must be heated to above 200 deg. F. before it can be easily vaporized in the furnace, preparatory to combustion. This heating is practically always accomplished by steam heaters, the oil being passed through coils around which steam is circulated.

When starting up a dead boiler, steam must be borrowed from a live one to heat the oil and to pump it to the furnaces. If, however, no steam is available, a wood or coal fire, with its attendant dirt, must be resorted to. If a furnace is to burn liquid fuel it should be constructed with that object in view. The best results cannot be obtained if the furnace has to be adaptable to burn coal or wood to raise steam and to switch over to oil when sufficient steam is raised to supply the furnaces with fuel heated to the proper temperature.

The "Reichenbach" fuel oil heater and starter has been designed to eliminate the coal or wood fire trouble when raising steam. It consists in the main of a pump, a heater coil and a kerosene torch. Fig. 1 is a partial longitudinal section of the heater and starter, and shows the internal construction. The oil inlet is connected to the main supply line, the pump drawing oil which has passed the suction strainers and delivering it, through the heater, to the furnaces. The kerosene gas burner, standing upright in the centre of the fire pot, heats the oil as it passes through the coil of pipe. The tank on the right carries the supply of kerosene, which is kept under a slight air pressure, by means of the small hand pump.

The base of the apparatus is in the form of a tray, and is made oil-tight, thus preventing the spreading of oil should any accidentally be spilt. The suction flange of the pump is tapped for the nipple and a shellac joint is placed between the flange and the tray. Where the kerosene supply pipes pass through the bottom, the holes are tapped and the pipe threaded through and secured with a lock nut.

The fire pot is provided with an air re-

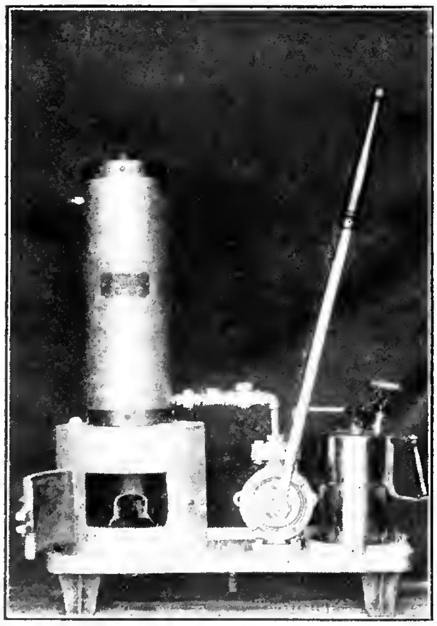


FIG. 2. THE "REICHENBACH" HEATER AND FUEL OIL STARTER.

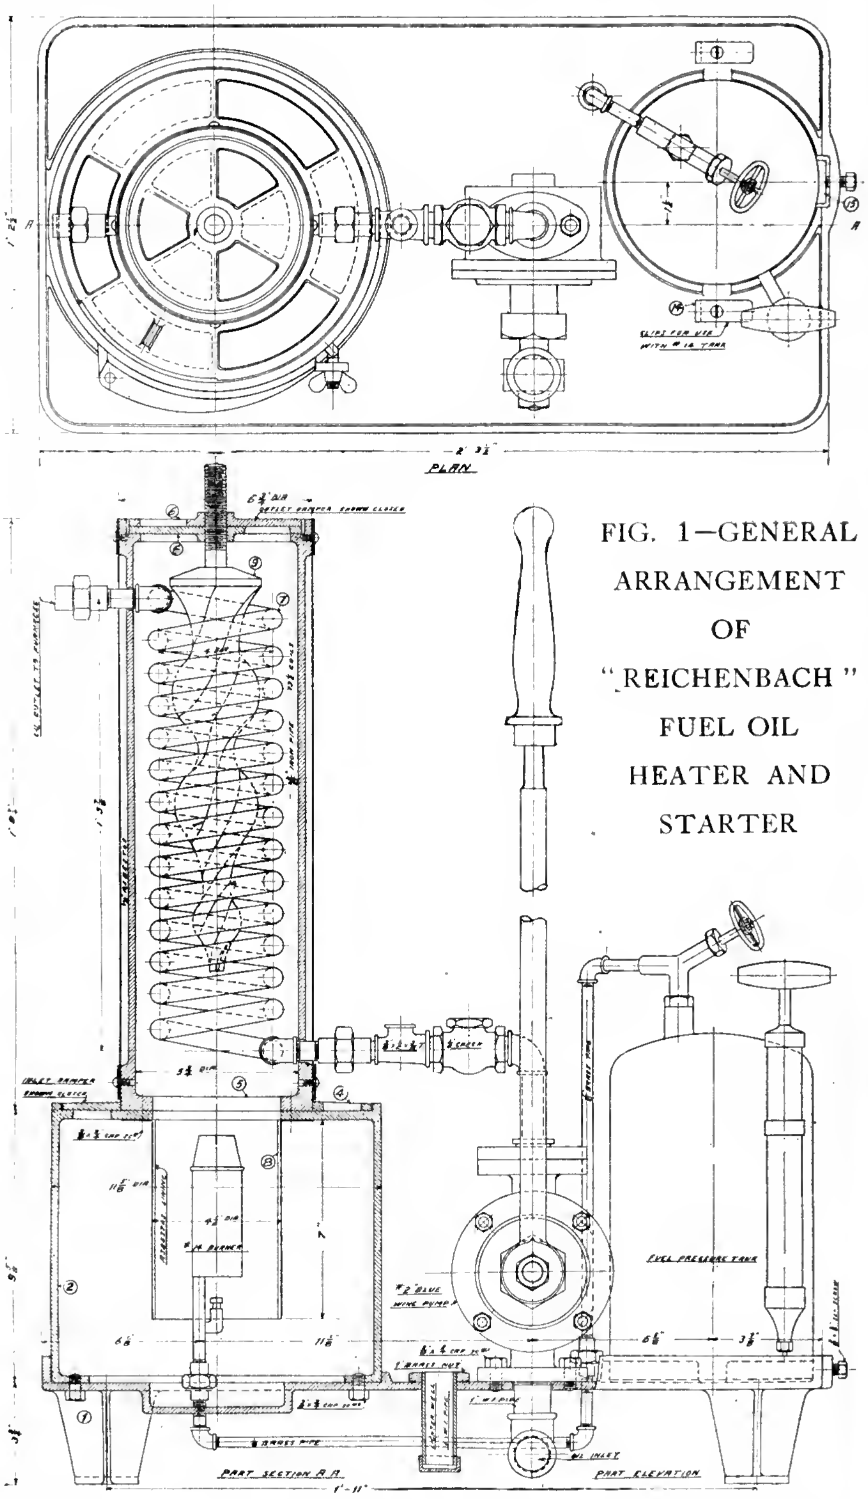

FIG. 1—GENERAL ARRANGEMENT OF "REICHENBACH" FUEL OIL HEATER AND STARTER

gulator at the top for supplying air to the burner, which obviates the necessity of keeping the door of the pot open when the machine is in use. Closing this regulator completely shuts off the air supply to the burner, and will extinguish it instantly. Another regulator is provided on the top of the heater barrel. To direct the air to the bottom of the pot, an asbestos-lined petticoat is provided; this can be seen through the open door in Fig. 2. The petticoat is constructed of three segments, the two segments facing the front being arranged to swing outwards to facilitate the removal of the burner.

The heater proper consists of a coil of 3/8-in. wrought iron pipe, through which the fuel oil is forced. The coil is carried in a cast iron cylinder, lagged with planished iron, and bound top and bottom with polished brass bands, the space between the cylinder and the lagging being filled with asbestos. A peculiar-shaped cast iron damper is provided to spread the flame from the burner and to direct it on the heater coils. The damper is hung on a threaded spindle, and its position can be regulated, up and down, to get the best heating effect.

The burner is lighted by placing an asbestos ball, which has been soaked in kerosene and lighted underneath, until the burner is hot enough to vaporize the kerosene, which vapor is then ignited. Heat from the burner thereafter automatically keeps it supplied with kerosene vapor. An extinguishing receptacle is provided between the fire pot and the pump, in which is kept the asbestos ball.

The pump is of the four-valve wing type, and can be arranged for motor or hand drive. Fig. 2 shows a hand-operated outfit. When installed, a return connection is made from the heater coil outlet to the pump suction, for the purpose of circulating the fuel oil when starting the heater.

We are indebted to A. F. Menzies, consulting engineer, New Westminster, B.C., for the foregoing data and illustrations.

NEW MODEL COUNTING MACHINE

THE saving of time and labor, the unerring accuracy, and the simplicity of operation of modern calculating machines, are but a few of the features which have combined to render them indispensable to progressive factory managers.

While formerly the applications of counting machines were principally in connection with clerical work, the benefits to be derived from their judicious use have caused them to come more closely in contact with actual manufacturing conditions.

Some marked improvements in design are shown in the new models of counting machines made by the Durant Manufacturing Company of Milwaukee, Wis. Model "D" counter, illustrated herewith, is a recent production by this firm, and amongst other advantages, it is fitted with a knob at the left of the case, by means of which the operator can instantly re-set the machine or clear it to zero.

MODEL "D" COUNTER.

These machines are being used to a very liberal extent on stamping presses, punches, screw machines, conveyors, etc., for automatically counting product as it comes from the machine.

In factory offices they are of great assistance in maintaining exact records of labor, material, sizes, weights, etc.; in fact, all of the elements of modern cost keeping can be handled to advantage with these machines. The manufacturers will gladly send, to interested parties, a copy of their catalogue, which illustrates the many advantages of these machines, and contains valuable suggestions regarding their adaptation to existing conditions.

PORTABLE CHANNEL IRON PUNCH

AN addition to their existing line of portable hand metal punches, has just been made by the W. A. Whitney Mfg. Co., Rockford, Ill., in the shape of a punch for handling channel iron.

The tool as can be observed from the illustration is designed principally for use on channel or other similar flanged work, the gap on the end of frame lever being so shaped that the tool can be slipped over the end of the section and moved along to the desired part.

The portable channel iron punch has a capacity of a 1/4 inch hole through 1/4 inch iron, and can punch to the centre of 4 inch channel iron having 1 1/2 inch flange. It uses the same punches and dies as the makers' No. 2 punch, all the small parts of each being interchangeable. The sizes of punches and dies are from 1/8 inch to 1/2 inch, advancing by 1-32 rds. Sheet metal workers in particular will appreciate the convenience of such a tool.

"WHITNEY" PORTABLE CHANNEL IRON PUNCH.

COMBINED PUNCH AND SHEAR

THIS compact combined punch and shear is capable of a variety of work on structural sections. The unit illustrated, and known as the No. 2 power machine, requires 3 horse-power to operate at its full capacity. It will punch a 1 1/2 inch hole in 1/2 inch iron, and a 1 inch hole in 3/4 inch iron. Angles up to 4 inches can be cut with it, also tees up to 3/8 in. x 2 1/2 in. When used for shearing flats, it will handle up to 5 in. x 1 in., and 7 in. x 3/4 in.

The main frame is built of two heavy castings which are bolted together in a vertical plane, allowing the machine to possess all the advantage due to compact assembly and accessibility while retaining the strength and rigidity of a solid casting.

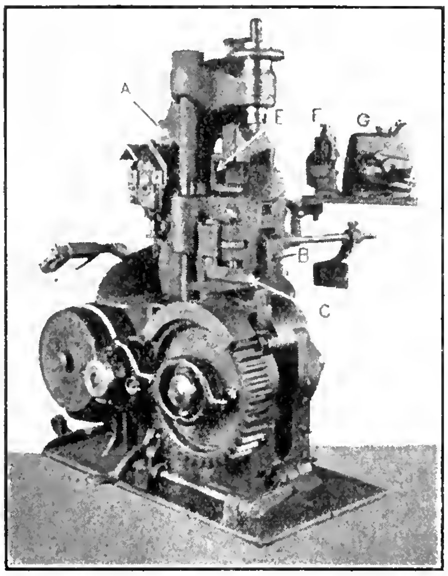
While the three principal operating features — angle cutting, punching and shearing—are individually provided in the design, the use of interchangeable attachments in the punch seat enables tees to be cut and the ends of angles trimmed.

The angle cutter A is located at the back of the machine. The shear is directly in front at B, where a flat is in position showing the adjustable guard C to prevent the work tilting up when being sheared.

The punch seat D which is part of the main frame is designed to accommodate fixtures E.F. and G. which are angle trimmer, punch, and tee cutter

respectively. A swinging shelf allows the change to be made quickly and easily. To the right of the machine is located the length gauge for shear.

All of the cutting parts operate vertically by means of two heavy steel rods actuated from the main shaft and guid-



COMBINATION PUNCH AND SHEAR.

ed in long lossess formed on the main frame.

By means of a suitable arrangement the punch can be brought down to the work and into centre punch mark before starting, thus insuring accurate work. In addition, the machine can be set to stop at each revolution or run continuously.

The total weight is 4,000 pounds; floor space, 4 ft. 6 in. x 3 ft.; pulleys 16 in. diameter for a 3-in. belt. Speed 450 rev. per min.

The builders of these mamachines are the Clark Foundry Co., Rumford, Maine.

SAND MACHINE

FOR castings that must be smooth, perfect, and regular, the preparation of the sand is of great importance. In addition to thoroughly mixing and tempering, the machine shown in Fig. 1 passes the material through a pair of rolls 12 to 18 times, thus pulverizing all small lumps and produces a sand which is smooth, velvety and tough, and possesses an even and regular vent. With the process as used here, one pair of rolls does the work of 12 to 18 pairs as usually set.

The Standard Sand & Machine Company, Cleveland, O., builds these machines in four sizes, equipping them regularly with floor hopper, revolving screen, elevator boot, bucket and chain elevator, and tempering gear. When desired, a three department proportioning hopper is supplied for controlling the amount of old sand, new sand, and dry binder; also a pump for liquid compounds. With the single hopper type, the materials are assembled in proper proportions before delivering to the hopper. With the three or more department hopper, the correct proportions are fed into the elevator boot from each hopper, and it is only necessary to keep the hoppers well supplied. The proportioned materials are delivered to the mixer by means of the bucket and chain elevator, and there the tempering liquids are introduced. The mixture is carried forward by the worm mixture to the feed end of the revolving drum which is provided with buckets inside to deliver the sand to the rolls within the drum. The pitch of the drum carries the mixture forward regularly so that all the sand is treated alike, and is discharged after being thoroughly rolled and blended.

One roll is stationary while the other is set against heavy compression springs which are adjustable. Sand rolled in this way is not ground into dust, and retains its grain thereby helping toward a perfect vent which is so essential. The machine is modern in every respect, steel gears, bronze bushed bearings, and steel roller bearing chains being used.

The three larger sizes are particularly suited for steel foundries. Fig. 2 shows the arrangement of these, the compression springs back of the adjustable rolls being clearly seen. One pair of rolls

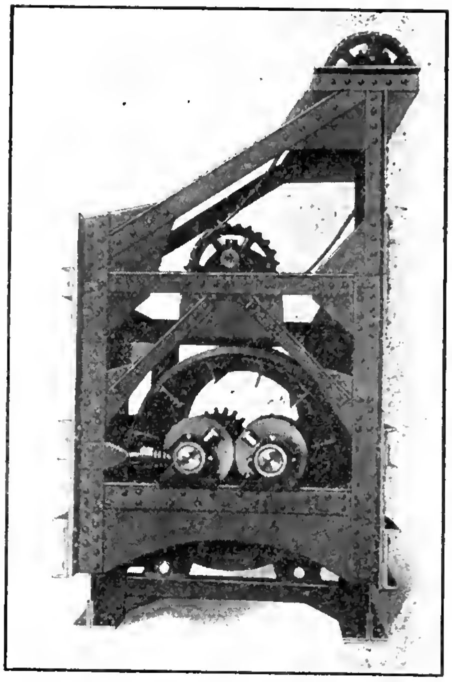


FIG. 2. SPECIAL SAND MACHINE FOR STEEL FOUNDRIES.

arranged in this manner will do the work of tandem or multiple rolls as the material can be passed through the same pair 9 to 36 times. These machines are designed to take the place of wet pan mills for core or facing sands.

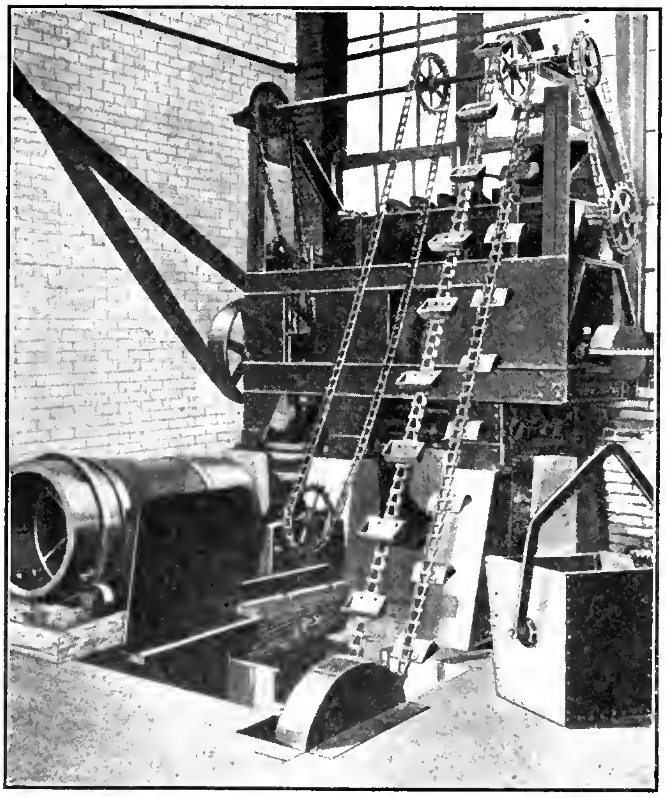

FIG. 1. MIXING, ROLLING AND BONDING MACHINE.

The No. 1 machine has a capacity of 160 cu. ft. per hour, with 10 horse-power; rolls 8 in. dia. x 4 ft. long; the No. 4 machine has a capacity of 360 cu. ft. per hour, with 20 horse-power; rolls 16 in. dia. x 6 ft. long. Floor space required is 10 ft. x 14 ft. and 15 ft. x 17 ft. respectively.

SMALL PLANTS TO HELP

D. A. THOMAS, representative of Lloyd George, British Minister of Munitions, had a lengthy conference with Sir Robert Borden recently, regarding the question of the manufacture of ammunition and big guns in Canada. Others present were Sir Sam Hughes, Sir Frederick Donaldson and Lionel Hitchens, the two latter being the British representatives who will be added to the reorganized shell commission. A scale of prices which the commission is willing to pay for munitions will be drawn up, and the practice of tendering done away with.

THE VALUE OF MANUFACTURING RECIPROCITY

JUST how much and just how little of a man's business should be known by his competitors is and always will be a moot question, and though at first sight anyone might be prepared to give a conclusive reply one way or the other, there are many qualifying features which prevent the average manufacturer from giving a definite reply offhand.

Apart from its desirability, which is questionable, or its efficiency which is still more questionable, the regime of quasi-secrecy inaugurated in connection with munitions manufacture may have a more or less permanent influence on many of our industrial organizations which must ultimately react to their disadvantage.

The advent of Government work has been characterized in the majority of cases by an absence of that spectacular display of industrial accomplishment which in ante-bellum days had been developed to a high degree. One result of this suppressed publicity has been to generate a feeling of mysterious importance in many enterprises whose pretensions were previously of a modest nature.

Without in any way detracting from the beneficial influence on the campaign which is to be obtained by keeping the enemy in complete ignorance of the extent of our munitions supply, it might be asked whether our own efficiency as munitions producers is not reduced as a result of excessive reticence regarding methods of production.

There are some persons who, in war time as in peace, look upon all journalists as necessary evils, to be borne with when necessary, and avoided when possible. Such individuals fail to realize that in standing in other people's light they also stand in their own.

No man is a hero to his valet, and few firms indeed are so highly regarded by all of their employees that they can afford to set themselves up as sphinx-like oracles. That liberty of employment which the North American workman cherishes as his inalienable birthright is one of the greatest factors in nullifying any attempts to form an Industrial Secrets Trust.

Ever since the munitions industry began to assume national proportions, we have consistently advocated, and devoted our efforts to the judicious dissemination of such technical and manufacturing information as could be of greatest immediate value to the numerous entrants into the ranks of producers. The knowledge that these efforts have not been valueless to many firms is our reward, and the manner in which nearly every concern has placed their experience at the disposal of others is proof of the soundness of our policy.

In another part of this issue we are privileged to place on record a few examples of extreme resourcefulness and development in specialized manufacturing, these being probably only some of many instances of improvised equipment throughout the country. Although the intrinsic value of such efforts may be confined to the originators, the ultimate suggestive value to manufacturers as a body may be very great, and wonderful possibilities may await designers and mechanics as the result of being thus jolted out of the rut of conventional design.

Reference might here be made to an instance in shell manufacture which emphasizes the service rendered by technical journals. In machining 3.3 inch shrapnel forgings, it was found necessary to make the wall of increasing thickness for a short distance near the mouth so as to provide ample metal for the internal thread after nosing in. When the making of 4.5 inch shells was being started, many makers spent a great deal of valuable time in ascertaining the proper taper to allow for the same operation. Meantime a new producer who was not bound by precedent, went ahead and dispensed with the taper, getting satisfactory results with one operation less. The fact that others were experiencing trouble by a too strict adherence to existing methods, did not increase the value of his own method to himself personally, while the lack of just such information delayed their progress perceptibly, besides giving rise to a feeling of disappointment, due to the absence of prompt and successful results.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, Que., Oct. 18, 1915.—The manufacture of munitions still retains first place in our metal-working plants. The demand for steel bars and billets continues unabated, and little change otherwise is evident. The various mills are operating right up to capacity, and many of them will be unable to take on further business for delivery this year. Consumers are even having difficulty in placing orders for 1916, as the mills decline to commit themselves for any extended period. As a matter of fact, it is hinted that advanced prices may prevail when they are in a position to take on more business.

Machine Tools and Supplies

The situation in the machine tool trade shows little change over that of the previous week. In some instances the delivery of necessary tools for shell production is being longer delayed, and several plants are meantime handicapped in their operations as a consequence. The demand for supplies continues brisk. However, some concerns who require duplicate machine parts to replace those broken or worn, and which must be procured from the United States, find great difficulty in securing these promptly.

Metals

Prices on the different metals are holding firm. Spelter shows some inclination to drop in price, while aluminum has advanced considerably over the quotations of the last week, being now around 60c.

Old Material

Scrap metals have shown no material change during the week, quotations remaining the same, with the exception of tea lead, which registers a slight increase.

Toronto, Ont., Oct. 19.—Indications point to a return of better trade conditions and a distinctly optimistic tone exists in business circles. The record harvest means prosperity in the West: war orders are keeping many factories fully employed, the adverse trade balance has been eliminated and railroad earnings now show an increase. The steel trade is generally considered to be the barometer of industrial conditions, and in its present state of great activity gives reasonable grounds for hoping that the improvement in business now taking place is something more than temporary. The influx of large sums of money resulting from war orders cannot help but stimulate manufacturing, and with the improvement in Canadian fiscal conditions will lead to a marked industrial development in the country.

Developments in the shell industry are pending and arrangements are being made for the manufacture of shells up to 12 in. calibre. The duties and responsibilities of the Shell Committee have increased to such an extent that a reconstitution of its personnel is being made to meet the demands of the situation. It is understood that the British Government have reserved large orders for shells for Canada, providing quick delivery can be made and at a fair price. A central ordnance factory for making big guns is under consideration: this branch of the industry will also come under the control of the Shell Committee.

Steel Market

The steel trade is in a very buoyant condition and the mills are operating at capacity. The market is very strong and prices on a number of steel products are advancing. Canadian mills are quoting iron and steel bars at 2.25c Toronto. Prices on wire are withdrawn pending a revision, which will be in an upward direction. Pittsburgh bars, plates and small shapes for Canadian business are quoted at 1.35c f.o.b. the mill, but are likely to be advanced again very shortly to 1.40c. The difficulty in obtaining quick delivery on steel products is illustrated by a Canadian buyer recently paying several dollars a ton premium for prompt delivery of structural material.

The placing of orders for larger shells which is anticipated, and the repeat orders for 18-pdr. shells in considerable quantity indicates that the steel companies will be very busy for some time to come. It is understood that the Dominion Steel Corporation have decided to embark on the manufacture of shells and that a large order will be placed with them for those of large calibre. This concern has for some time been actively engaged in producing steel for shells but not turning out the complete product.

The galvanized sheet trade is somewhat unsettled. Although the price of spelter has declined, manufacturers of sheets are hesitating before making any further change since the revision announced recently. The semi-finished steel situation is steadily becoming a factor in the present sheet market. The unusual conditions in sheets have upset the price relationship as between gauges. Galvanizers are asking more for the light gauges of sheets than for the heavy gauges because of the greater amount of spelter required per ton in the former.

All the mills in the States are running to capacity on account of the tremendous buying of all kinds of steel products. Steel for near-by deliveries is almost impossible to get at any price. The heaviest demand is for round bars and blooms for shells. Prices are advancing, no business being placed for bars at less than 1.40c Pittsburgh. Forging billets have advanved $1 per ton and are now being quoted at $34 base, f.o.b. Pittsburgh. Prevailing prices on wire are strong, and it is not improbable that quotations will be put up $1 or $2 per ton in the near future.

Pig Iron

The chief interest in the market is in steel making grades, with low-phosphorous iron still the feature. Canadian buyers have taken considerable tonnage from the States. Among these is the Canadian Steel Foundries, who have bought 7,000 tons recently and have inquired for 5,000 tons additional, the price being $25 at the furnaces. Foundry grades are quiet at unchanged prices.

Machine Tools

Machine tool dealers are anticipating a period of considerable activity in the near future when it is expected that the orders for the larger calibre shells will be ready to be placed. A few tentative inquiries have already been received for large size lathes, but up to the present few orders have been given out. The great problem at present as regards new equipment is the question of delivery. Builders are in a sold-up condition and the supply of suitable second-hand tools is rapidly decreasing.

Supplies

The demand for machine shop and mill supplies continues good and prices are holding very firm. Prices of high-speed twist drills are withdrawn on account of the continued advance in high-speed steel. In regard to the latter, the situation shows no improvement and prices are away up; supplies in sufficiently large quantities are also still difficult to obtain. Prices of waste are very firm but unchanged. Turpentine has advanced 1c and is now quoted at 65c per gallon.

Metal Market

The metal market is dull and there is little of interest to note. Tin and spelter are lower, but aluminum has advanced. The copper market is steady as a result of good demand for war munitions which shows no signs of abatement. The lead market is unchanged, but the position of this metal is a good one. There is still some scarcity in supplies of antimony, but the demand has not improved and quotations are stationary. Prices of solders are unchanged, but have a weak

tendency due to tin having declined. There is no change locally in the general situation. The general trend of business continues the same, metal for munitions constituting the principal demand.

Tin.—The market is quiet and lower, and comparatively little interest is being shown by consumers. The one influence dominating the tin market in New York is the expectation that the British Government will impose a 10 per cent. tax on its importation; there is as yet no official confirmation of any such intention. No large business is looked for until that question is settled, as consumers are content to wait. Tin has declined 1c locally and is quoted at 37c per pound.

Copper.—The market is very dull, but prices are holding firm. Buyers have fair stocks on hand, but are reaching a point where they will have to take on additional supplies. Producers are well stocked up, but are not inclined to offer any price concessions. Quotations are steady and unchanged at 19½c per pound.

Spelter.—The market for spot is weaker owing to the absence of interest on the part of consumers. Another influence lending weakness was a decline in the London market. Spelter has declined 1c locally, and is quoted at 17c per pound.

Lead.—The market is quiet and unchanged. It is reported that Canadian consumers have closed contracts for some good amounts of lead in addition to those recently placed. Quotations are firm at 6¼c per pound.

Antimony.—There is no change in the situation and the demand does not show much improvement. Quotations are unchanged at 35c per pound.

Aluminum.—Supplies are diminishing and the demand is increasing heavily, due to war orders. Quotations have reached a record level and are nominal at 60c per pound.

LOOKING FOR NICKEL

VICKERS, LTD., the well-known armament manufacturers, are financing an exploration expedition to the Fond du Lac region lying northeast of Lake Athabasca, in northern Alberta, in search of nickel deposits which are believed to occur extensively in that country.

Some months ago H. V. Dardier, a prospector, returned from Fond du Lac with rich specimens of nickel ore and went to England in order to interest British capitalists. He has been placed in charge of the expedition, which is on a large scale, comprising 25 engineers, assayers and mineralogists in addition to a large force of laborers.

They take with them machinery valued at $50,000 and supplies costing $10,000, being prepared for a long stay in order to thoroughly prospect the region. The total cost of the enterprise will amount to fully $100,000.

CANADIAN COMMERCIAL INTELLIGENCE SERVICE

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Comissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Kingston, Ont.—Davis & Son contemplate installing equipment in their power house.

Owen Sound, Ont.—The Owen Sound Ironworks are equipping their plant for making shells.

Welland, Ont.—It is reported that preparations are being made to reopen the plant of the Canadian Steel Foundries.

Owen Sound, Ont.—The Canadian Malleable Iron Co., will install equipment for making high explosive shells.

Port Moody, B.C.—The Port Moody Steel Works is contemplating the erection of a plant to cost upwards of $100,000.

Calgary, Alta.—The Alberta Hydro-Electric Power Co. will build a power plant here. Ald. Fawkes is consulting engineer.

Jacksonboro, Ont.—The Mattagami Pulp & Paper Co. will commence at once the erection of pulp and paper mills at Smooth Rock Falls, on the Mattagami River, near here, to cost $2,000,000.

Bay of Islands, Nfld.—Joseph Salters & Sons, of North Sidney, C.B., have applied for permission to develop water powers near here.

Walkerville, Ont.—The Canadian Duplex Steam Trap Co., which was recently incorporated with a capital of $40,000, will establish a plant here.

Pembroke, Ont.—Thomas Pink Co. are installing new machinery for making shells. The new plant will be a duplicate of the original one and will double the company's output.

Kingston, Ont.—A. Davis & Son are in the market for one 125 to 150 h.p. Wheelock engine; one 100-kw., 550-volts, 60-cycle, 3-phase alternating current generator, and one 100-kw. direct-connected, 550-volts, 60-cycle, 3-phase alternating current generator set.

Merritt, B.C.—The British Columbia Copper Co. proposes to spend in the neighborhood of $500,000 in the erection of a concentrating plant at their Copper Mountain properties. This is to be operated by an electric power plant to be erected either at Princeton or Tulameen, according to reports, it being estimated that it will take at least $300,000 to erect and equip same.

Ottawa, Ont.—An important new factory for the manufacture of munitions of war is to be established at Renfrew, Ont., entitled, "O'Brien's Munitions, Ltd." The company was incorporated last week with a capital stock of two million dollars. It is understood that M. J. O'Brien, the well-known contractor, is the leading spirit in the enterprise, and that his investment will be half a million dollars.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing. Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Messrs. S. Ruperti and Alexsieff, care Military Attache, Russian Embassy, Washington, D.C.

Municipal

Winnipeg, Man.—By a vote of 104 to 64 the ratepayers of Assiniboia defeated the $27,000 incinerator by-law on Oct. 9.

Port Coquitlam, B.C.—A by-law has been passed by the ratepayers to raise $35,000 for the purpose of installing a civic water system.

St. Andrews, N.B.—The Town Council propose making extensions to the waterworks system at a cost estimated between $20,000 and $30,000.

St. Agathe des Monts, Que.—A sewage system will be installed here which will include a pumping station. Ouimet & Lesage of Montreal are the engineers.

Watrous, Sask.—A by-law will be voted on by the ratepayers on Oct. 26 to authorize the expenditure of $49,423 for the construction of a waterworks system.

Niagara Falls, Ont.—It is proposed to spend $14,000 on the purchase of the machinery and equipment of the city electric power station. A by-law will be submitted on November 3.

Whitby, Ont.—A macadamized road 26 miles in length, to cost $310,000, was recommended by Provincial Highways Engineer W. A. Maclean at a meeting of the Kingston Road Improvement Committee here, on Oct. 14. Representatives were present from all the towns and townships interested, also Controller Foster and Commissioner Harris from Toronto, which is backing the project.

Mimico, Ont.—Contracts for the new sanitary system of Mimico and New Toronto were awarded on Oct. 8 at a special meeting of the commission recently appointed. Harvey, Stewart & Co., of Nova Scotia, were the successful bidders for the construction of the sewage system, at the figure of $64,493. F. F. Frue, of Toronto, will build the disposal plant, the estimate being $15,253, and the Dominion Sewer Pipe Co. was awarded the contract for the vitrified pipes and segment blocks used in the system.

General Industrial

Guelph, Ont.—Fire on Oct. 14 did $15,000 damage to the Colonial Knitting Co. plant here.

Lindsay, Ont.—Horn Bros. have not completed arrangements for the rebuilding of their factory.

Vernon, B.C.—R. J. Graham & Co., of Belleville, Ont., will build a factory here for evaporating vegetables.

Halifax, N.S.—The Nova Scotia Underwear Co. mills at Eureka, were totally destroyed by fire on Oct. 13. The loss is covered by $150,000 insurance.

Systematized Shell Production: Methods and Results

Staff Article

Efficient teamwork by any organization is only possible when a clear and complete understanding exists between all members. Frequent conferences between responsible parties for open discussion of common problems, effectively prevents subsequent delays due to overlapping or failure of any particular department to maintain scheduled output.

SHELL making in Canada has now reached the stage where it might seem impossible to further enlighten those interested in any way, with the manufacture of these munitions of war. While this may be true regarding the various operations required to produce the completed shell, the system whereby these operations are performed and the methods devised are often so different, and correspondingly interesting, that a great deal can yet be said on the methods adopted in the various plants.

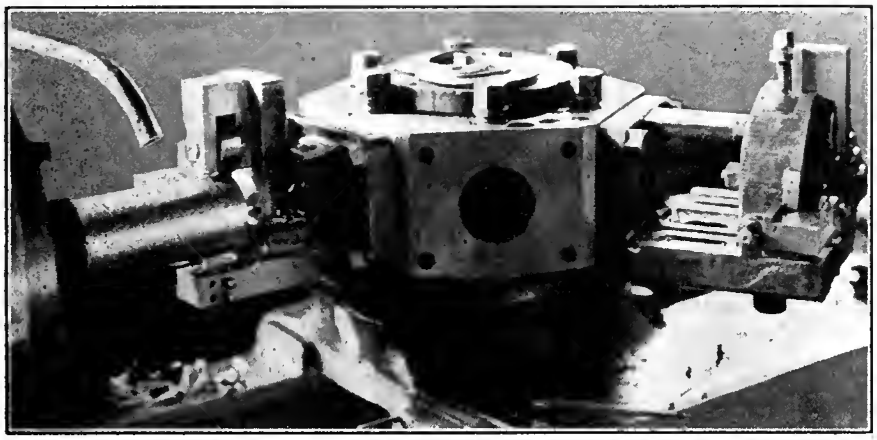

FIG. 1—OUTSIDE ROUGH TURNING ON "LIBBY" TURRET LATHE

It is strangely true that no two men think alike, and it is also true that no two shops (even if they are producing the same class of goods) are similarly equipped. It is, therefore, reasonable to expect, when the same proposition is placed before a number of men, each surrounded by his own individual requirements and experience, that the final solution to the same problem—while having the same answer—may vary to such an extent in detail, as to appear entirely different. It is this variation in detail that is constantly keeping the attention of the readers of trade papers in close touch with the many ingenious methods and devices which are being adopted for the maximum output of this much needed article.

While there has been quite a number of plants specially constructed for the manufacture of 3.3 and 4.5 shells, there are a far greater number who have taken the opportunity of the times and equipped their present factory with the necessary tools for producing these shells.

In the present situation, when the desired tools are practically unobtainable, much thought and consideration have been given to the designing and developing of jigs and attachments, whereby the present equipment (often of ancient origin) can be used to the best advantage.

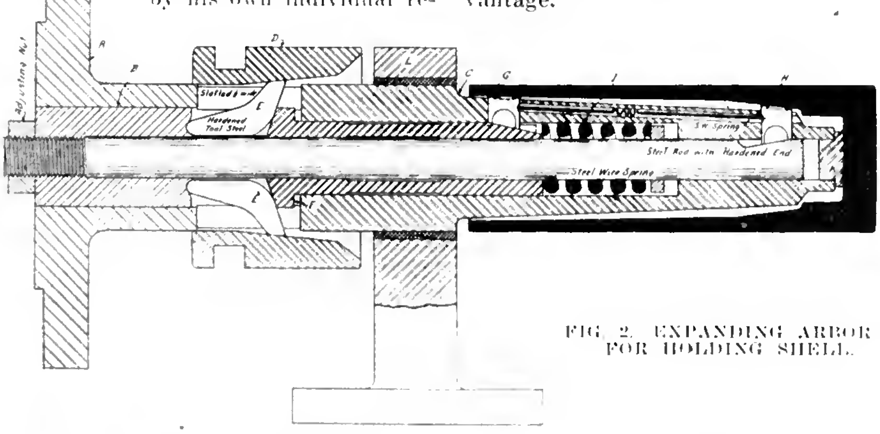

FIG. 2. EXPANDING ARBOR FOR HOLDING SHELL.

Plant Organization

When the plant herein described, first considered the manufacture of shells, every detail was carefully considered before the actual work was commenced. One of the chief features in this connection was the organization of a private shell committee, composed of the manager, superintendent and foremen of the various departments. From the commencement of operations this committee has met regularly to discuss ways and means whereby the production of shells can be handled to the best advantage. The success of this firm, in producing shells of first-class quality, is largely due to the methods of co-operation among the members of this committee. Suggestions and ideas are here advanced and every detail carefully considered before any actual work is performed.

That this method of solving the problems of shell making has met with satisfactory results, is shown in the report, that this firm have one of the best records of any in Canada. The efficiency, in series of 120 has averaged 117, and in some cases 118, which is practically perfect. In consideration of this showing

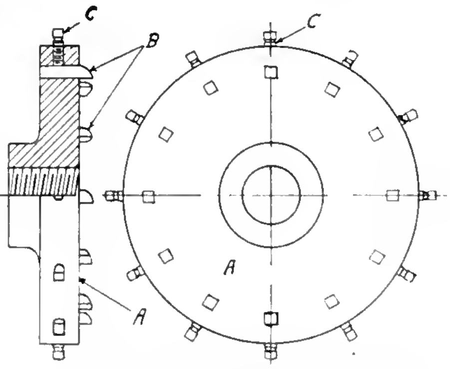

FIG. 1A. CUTTER FOR FACING OFF SHELL BASES.

they are now making series of 250 in place of the ordinary quantity of 120.

In addition to the good showing being made in production, this firm have designed and installed several novel and useful attachments in connection with the manufacture of shells which have proved highly satisfactory; some of these devices are now being used by other plants with excellent results.

Shell Production

The sequence of operations in this plant is somewhat similar to that in other establishments; however there are several very interesting devices that are worthy of description.

Roughing to Length

The open end of the forgings are cut off in a Hall cutting off machine and the

base is faced off on a Bertram 20-inch gap lathe; the shells are held in a jig on the saddle while a home-made milling cutter, similar to Fig. 1A is used for facing the end. Another Bertram 20-inch shafting lathe is also being fitted up to perform this operation.

Outside Rough Turning

The outside rough turning is accomplished on three single spindle Jones & Lamson flat turret machines, and one Libby turret lathe. A view of the operation on the Libby lathe is shown in Fig. 1. The shell is held on the expanding arbor shown in Fig. 2. The flange A is secured to the chuck or face plate of the lathe. Within this piece is the steel regulating bush B, which is held in position by a nut at the back. Secured to flange A is the cast steel arbor C, which carries the expanding mechanism. When the rough shell has been placed on the arbor, sliding sleeve D is advanced by means of a lever; the internal tapered slots in this piece now act upon the three dogs E, which force the hardened steel bush F forward and pull the central rod backward; the hardened steel dogs G and H are thereupon forced outward by tapered grooves formed in bush F, and the rod end respectively. These dogs are arranged in groups of three and centralize the forging very accurately.

After the shell has been turned sleeve D is moved back, when the spring I acting on the bush F and a steel collar fastened to the shaft, causes a relative movement between the bush and the shaft, removing the pressure on the end of the dogs G and H, whereupon they contract and allow the shell to be removed. A hardened steel plug is placed in the end of the arbor to gauge the lateral position of the shell. To insure rigidity the steady head L is used; this is made of cast iron with a babbited bearing.

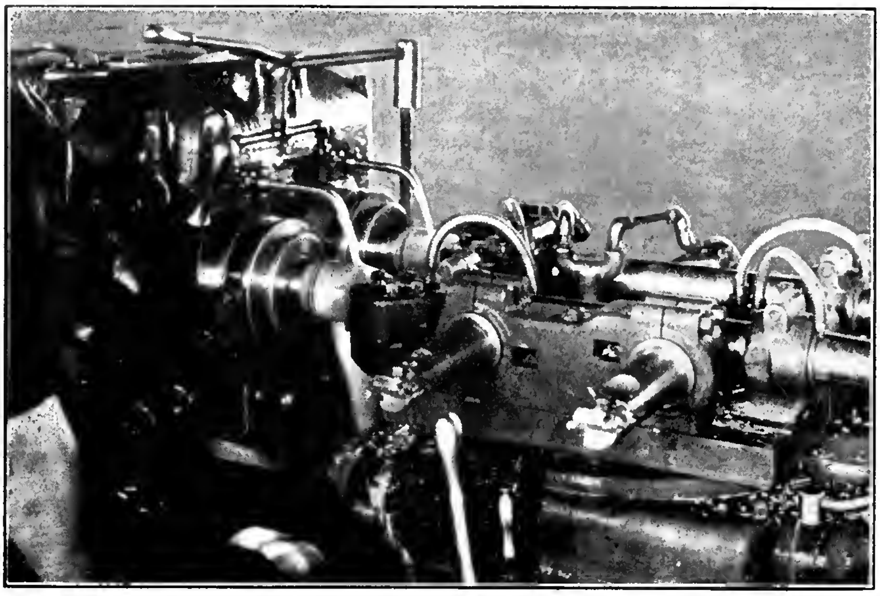

FIG. 3—INSIDE BORING ON JONES & LAMSON DOUBLE SPINDLE FLAT TURRET LATHE

Inside Boring

The inside boring is done on four Jones & Lamson double spindle flat turret lathes, the operation being shown in Fig. 3. After the shells are bored the driving band groove is formed on an 18-inch Bertram lathe with Bertram waving and undercutting attachments.

Hardening and Tempering

The hardening of the shells which is done in much the same way as already described in previous articles is shown in Fig. 4 The furnaces used are two of Dominion Bridge Co. make, while four others are being installed. The oil bath is placed inside a larger tank which gives a space about 10 inches completely around it; this space is filled with cooling water which is in continual circulation. In addition, the oil is further cooled by being pumped through a suitably arranged cooling tank. After the shells have been tempered they are placed in line to give sufficient annealing for further machining.

The scale and lime is then brushed off and the part of the base diameter back of the copper band groove is ground to size.

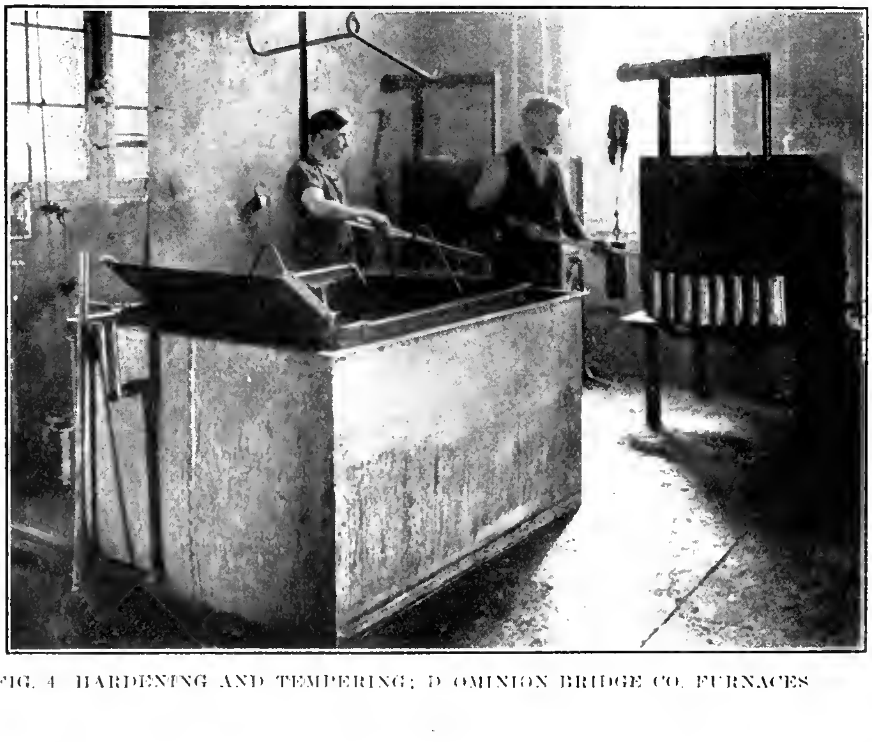

FIG. 4 HARDENING AND TEMPERING; DOMINION BRIDGE CO. FURNACES

Nosing

The nose is now heated in a lead bath to a temperature of about 1,500 degs. F., and formed to shape in a Brown-Boggs No. 320 A geared straight side press.

The nose of the shell is finished in three Jones & Lamson single spindle flat turret lathes. The profile of the outside is formed, the nose bored and threaded, internal profile formed and the end beveled. A sizing tap is then run in by hand.

Grinding and Cleaning

The body diameter and nose are then ground to final size and shape in four Ford-Smith grinders. After the shells are thoroughly cleaned they are stamped in a Brown-Boggs stamping machine.

Putting on Copper Band

The copper bands are pressed on in a 150-ton hydraulic press constructed by the Lymburner Co., of Montreal. A sketch of this press is shown in Fig. 5. This press was designed to operate with a maximum pressure of 1,500 lbs. per sq. inch. To avoid any excess pressure taking effect upon the shell (which would have a tendency to distort it) a relief valve, set to open at the desired limit of pressure was placed on the feed pipe at one of the hydraulic connections as shown at A.

The sectional view of Fig. 5 shows very clearly the detail construction of this press. Oil is used for operating the press and is supplied by pressure pump shown in Fig. 6. The fluid passes through the 3/8 inch pipes B and enters the space between the pistons C and the movable cylinders D. As the pressure risest o 1,500 lbs. per sq. in., it is transmitted to the area of the piston, which is $6.5^2 \times .7854 =$ 33.18 sq. inches.

At a pressure of 1,500 lbs. per square inch this gives a total pressure acting on each cylinder of $1,500 \times 33.18 =$ 49,770 lbs., or about 25 tons. This pressure is transmitted through the die blocks E to the copper band. The coil springs F are to force the cylinders back after the fluid has been released.

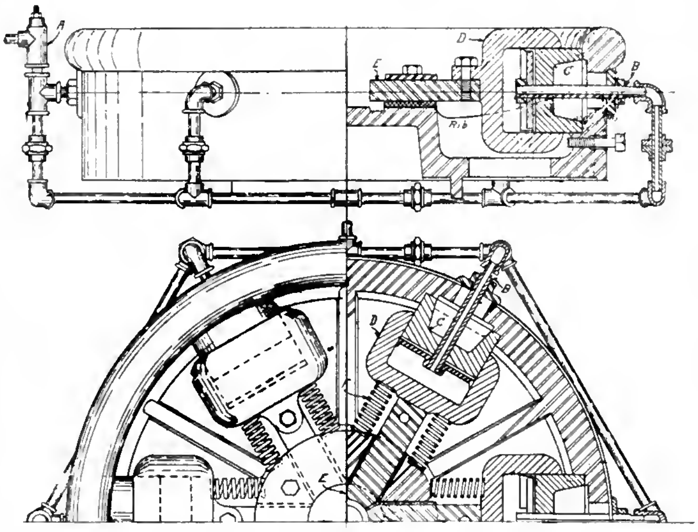

FIG. 5. "LYMBURNER" HYDRAULIC PRESS, 150 TONS CAPACITY

Pressure Pump

The pressure pump—which supplies fluid to this press—also designed and constructed by the Lymburner Co., is shown in Fig. 6; this pump, which is of the duplex type, has two plungers of 7/8 inch in diameter and a stroke of 2 inch. The fluid is drawn from the reservoir A, through the check valve B, up through the pipe C and into the cylinder chamber D, during the intake stroke of the plunger. The discharge stroke of the plunger forces the fluid through the supply pipe E to the six cylinders of the press. When the pressure has reached 1,500 lbs. per sq. inch on the gauge the controlling lever is released and the fluid passes back into the reservoir A.

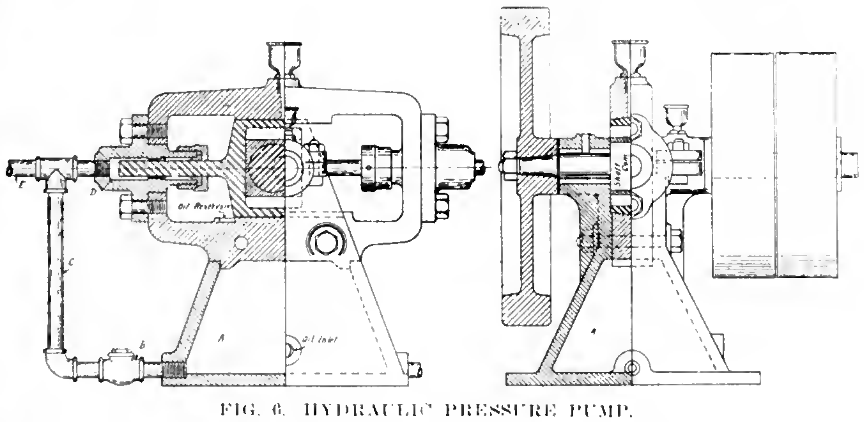

FIG. 6. HYDRAULIC PRESSURE PUMP.

Copper Band Turning

After the driving band has been pressed on the shells are taken to a Rahn & Carpenter 16-inch lathe shown in Fig. 7. The device here shown is the Lymburner copper band turning attachment. Besides this special turning device there are some other interesting contrivances to be seen here. One of these is a special draw-in collet chuck operated by the toggle gear described below, which has been successfully adapted for use on several of the machines used throughout the factory.

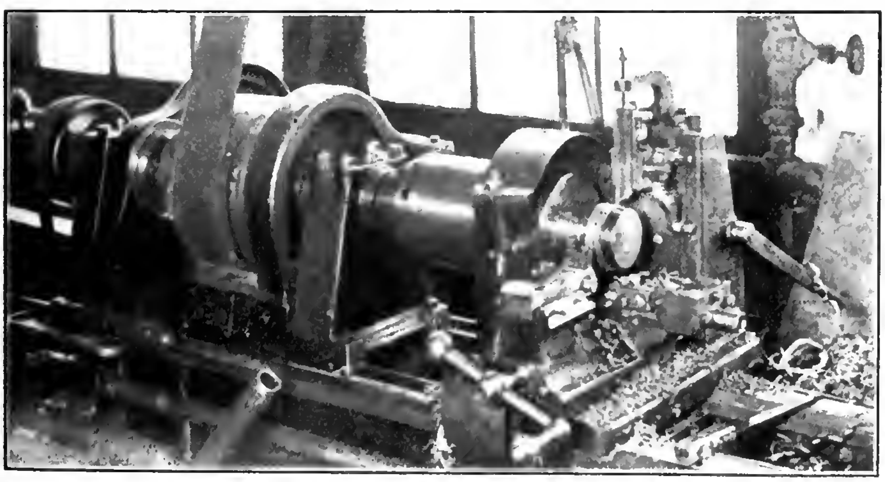

FIG. 7 TURNING COPPER BANDS

Special Chuck

The details of the chuck (designed and constructed in the shop), which is used on a numof machines, is shown in Fig. 8. The body of the chuck A is threaded to fit the screw on the lathe spindle and turned on interior to the desired dimensions, to receive the split collet B. Inside of this split collet is another split bush C, turned to fit the collet B and ground out (when in position) to fit the diameter of the finished shell; this inner bush is held in position by two screws D, which pass through slots in the collet B. This allows the collet B to be moved laterally by means of the rod E, which connects with the toggle arrangement at the rear of the lathe spindle.

Toggle Arrangement

The toggle arrangement is shown in detail in the sketch Fig. 10. This device which has displaced the hand wheel previously used was also designed and installed by the superintendent of the shop and is proving very efficient.

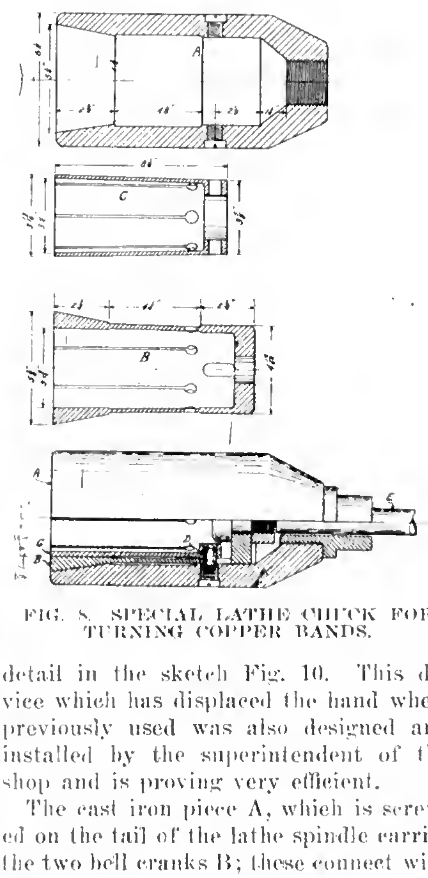

FIG. 8. SPECIAL LATHE CHUCK FOR TURNING COPPER BANDS.

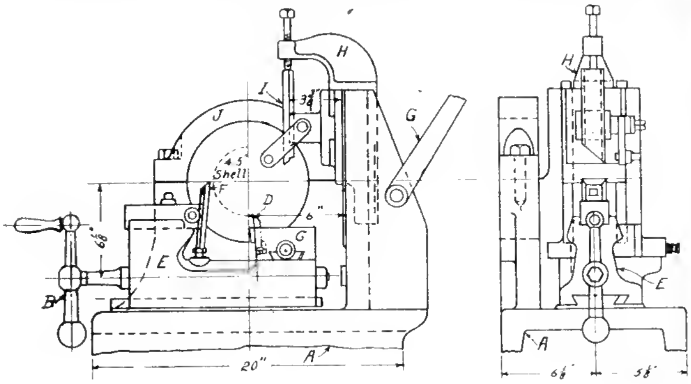
The cast iron piece A, which is screwed on the tail of the lathe spindle carries the two bell cranks B; these connect with the sliding collar C, by means of the links D. The short arm of the bell cranks B fits into a groove in the adjustable col-

lar E, which controls the grip upon the chuck. The slotted end of the lever F works on the pin of a steel ring G; the collar C revolves freely, lateral play be-



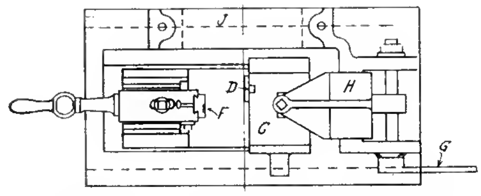


FIG. 9. "LYMBURNER" COPPER BAND TURNING ATTACHMENT.

ing adjusted by the nut H. The bracket I, which is secured to the bed of the lathe, carries the arm F, and likewise supports the outer end of the rod J.

Band Turning Device

Fig. 9 shows a sketch of the Lymburner band turning attachment which has been doing excellent work in the finishing of the copper rifling band, on 3.3 and 4.5 British shells and also French and Russian. The frame A of the device is secured to the shears of the lathe in the desired position. By turning the handle B, the slide C with tool D travels in a direction parallel with the lathe spindle; this is obtained by means of a pair of spiral gears beneath the slide C. The tool D is in such a position that the copper is roughed off with a single point tool.

While the tool D is roughing the band off, the slide E and tool F are advancing toward the work; when the roughing is finished the forming tool F shapes the band. Lever G is then pulled forward and by action of the pinion and rack, the slide H is forced down, and the tool I sizes and polishes the copper band. The part of the frame J acts as a steady head.

Assembling

Fig. 11 shows the assembling bench. The brass tube is screwed into the diaphragm and the shell filled with bullets and jarred with an air vibrator; they are then filled with resin from the two electric heated furnaces shown at either end of Fig. 11. The man at the right of the figure paints the brass sockets with red lead and enters it into the nose of the shell; it is then passed across to the man in the centre who places the shell in a special machine shown in Fig. 12, where the socket is screwed home by the power supplied by the machine. After the socket is screwed in the shells pass to a lad at the end of the bench where the tubes are soldered with two electric irons; from here they go to the machine shown in the background of Fig. 11, where the sockets are finish turned. The arrangement here is so compact that the shells pass from one operator to the other without the men taking more than one step.

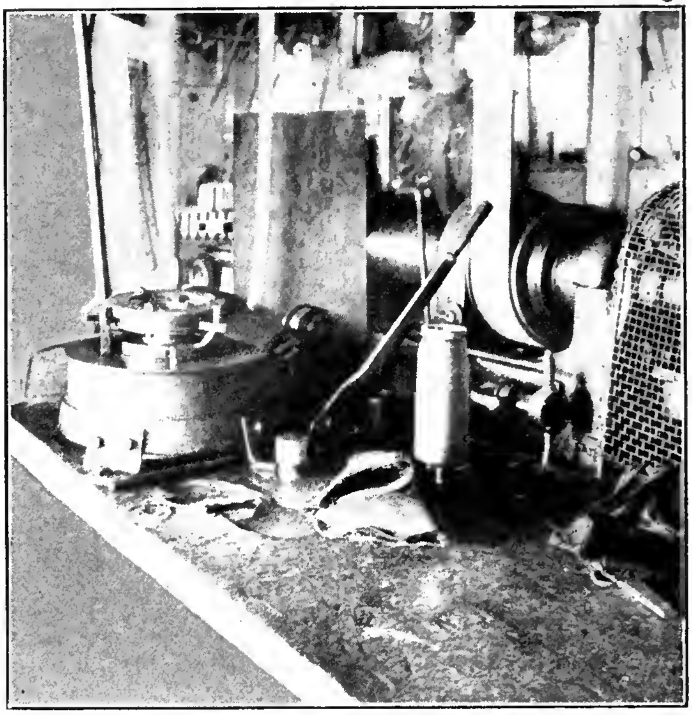

FIG. 12 -SCREWING IN SOCKETS WITH SPECIAL DEVICE

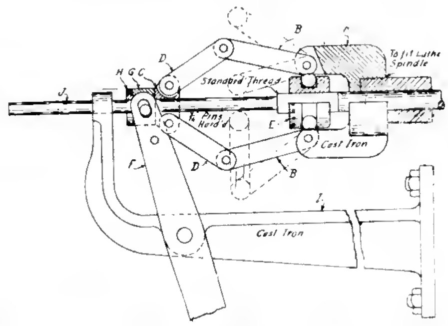

FIG. 10. TOGGLE JOINT FOR LATHE CHUCKS.

Socket Screwing Machine

The details of the socket screwing machine (designed and built by the Lymburner Co.) are shown in Fig. 13. The frame A of the machine is secured to the bench; this casting is bored to receive the split collet B, which is operated by the rod C as shown. This arrangement of the handwheel has been displaced by the toggle device described above, which gives better satisfaction, with increased production. The copper band, being of a larger diameter than the body of the shell, it is necessary to place an auxiliary bush over the shell before placing in the chuck.

On the outer diameter of the centre casting A is placed the large worm gear D, which meshes with

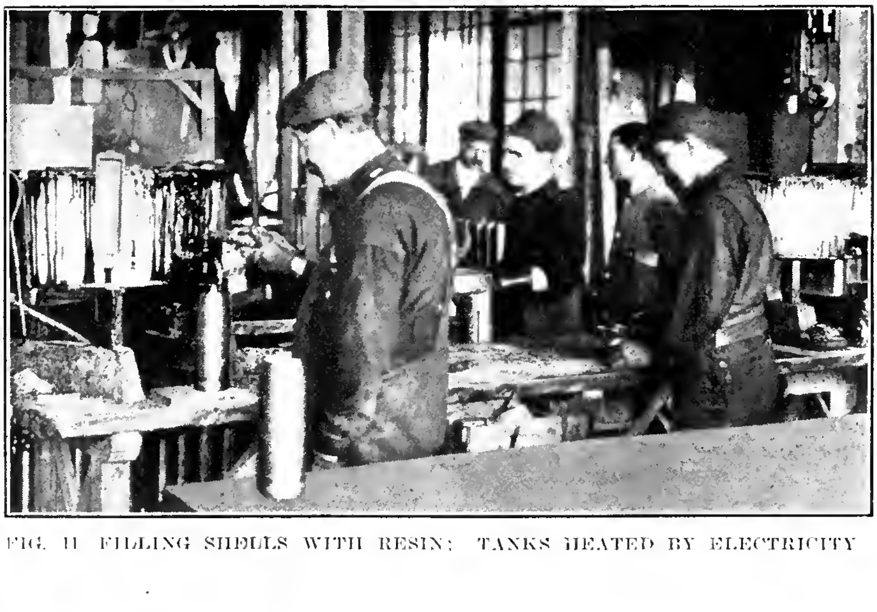

FIG. 11 FILLING SHELLS WITH RESIN; TANKS HEATED BY ELECTRICITY

the worm E. The shaft F, upon which the worm is secured, runs in brass bushes held in the housing of the frame A. The end thrust is taken up by the fibre collars shown, the position of which can be adjusted by the threaded brass bushes. The driving pulley G is keyed to the end of the shaft F. Varying force can be applied to the screwing arrangement by means of the idler pulley H, which revolves on a pin secured in the arm I; on the opposite end of the shaft that carries the

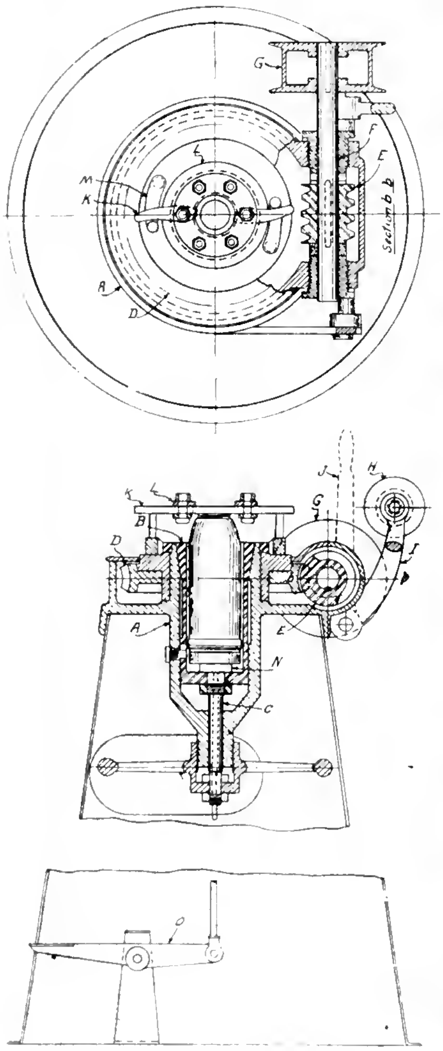

FIG. 13. SPECIAL APPARATUS FOR SCREWING IN BRASS SOCKETS.

arm I is the lever J, which controls the tension put upon the belt. In preference to the two-point driving arrangement shown in Fig. 13, a three-point drive is now being used. The dogs K, with teeth on the inner end, are pivoted on studs in the collar L. These dogs come in contact with self adjusting bell cranks M mounted in the worm gear.

Operation

The operation is as follows: the slip bush is placed over the shell and placed in the chuck and resting on the ejector

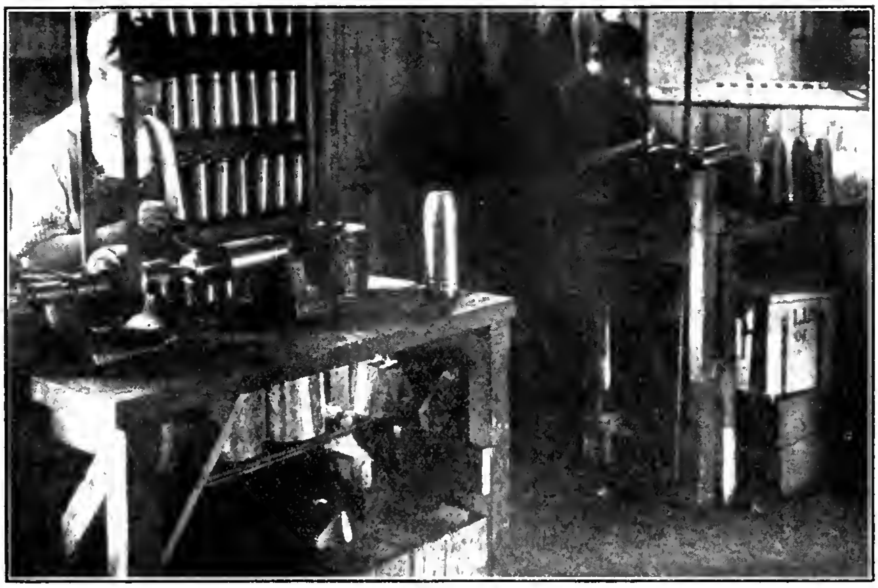

FIG. 14. PAINTING AND DRYING SHELLS.

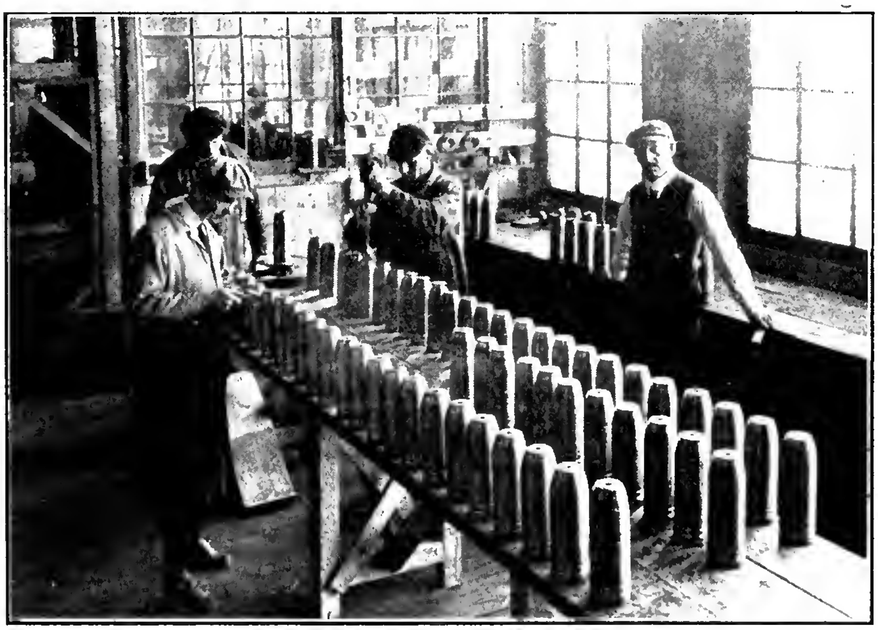

FIG. 15. INSPECTION DEPARTMENT.

FIG. 16. SHELL COMMITTEE OF LYMBURNER'S, MONTREAL
From left to right: Mr. Halley, Mr. Lymburner, Mr. Auger, Mr. Lemieux, Mr. Cotsby, Mr. Lacelx, Mr. Duplessis

rod N, which is raised by means of the foot treadle O. The shell is then lowered to position and the chuck tightened by the lever controlling the toggle device (not shown); the driving collar is then placed over the shell and the lever J is brought forward and the pins M coming in contact with the dogs K cause the teeth on the inner end to grip and turn the socket. When the socket is screwed home the lever J is released, driving collar removed and the shell ejected by means of the foot treadle.

Cleaning and Painting

After the sockets are finish-turned the tube and powder chamber are cleaned by a blast of compressed air and inspected; they are then taken to the painting and drying shelves, shown in Fig. 14.

Fig. 15 shows a view of the inspection room where the shells are finally tested before being crated.

Shell Committee

The Shell Committee, that is largely responsible for the successful production and high test percentage of this plant, is shown in Fig. 16.

USING A 3-PHASE MOTOR AS A SINGLE PHASE CONVERTER.

By Sidney Rose.

A THREE-PHASE current can be obtained from a three-phase induction motor running on a single phase line, but as the motor will not start on single phase current, some means must be provided to bring it up to speed. This can be done by giving the motor pulley a sharp turn; but a still better method is that shown in Fig. 1. A reaction or choke coal is indicated at L, while R is a non-inductive resistance. These may easily be proportioned, so that there is a difference in phase sufficient to start the motor from rest and bring it up to speed.

When the motor is up to speed, the reaction coil and resistance may be cut out by means of a switch, and it will continue to run. The three-phase motor when up to speed will give out a three-phase current of the same frequency as that of the single phase current supplied to its stator when connected, as shown in Fig. 2. This is due to the fact that in the short circuited secondary or rotor there exists a constant rotating field, notwithstanding the fact that the current exciting the primary or stator is single phase, and, therefore produces only a simple alternating field. This is explained by the characteristic property of the short circuited secondary or rotor.

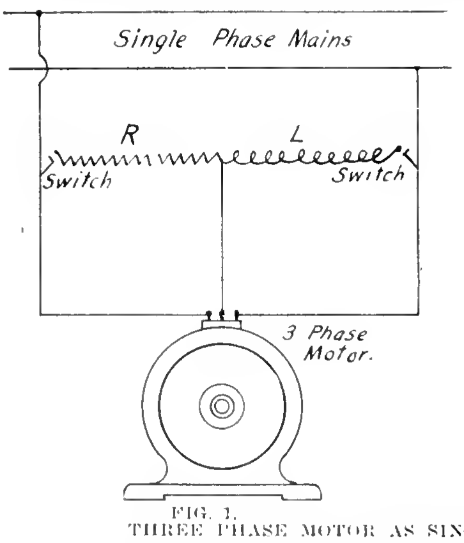

FIG. 1.

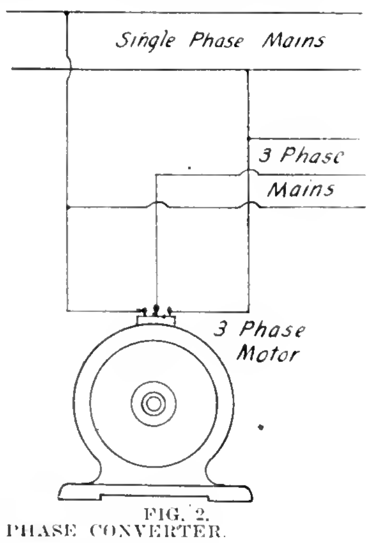

FIG. 2.

THREE PHASE MOTOR AS SINGLE PHASE CONVERTER.

PLATING BY IMPACT

A PROCESS of plating by impact has been in course of development by C. F. Jenkins ,of Washington, D.C., says the Journal of the Franklin Institute. This process can best be understood if it is remembered that, when an electric lamp bulb gives way, a discoloration of the inside of the bulb occurs, and also that when a fuse plug "blows" the mica cover is discolored. This color is black when the fuse is of lead, but it is a reddish color when a piece of copper wire is used.

This would seem to indicate some kind of deposit resulting from the blowing of the fuse, that it is not completely volatilized. Under a magnification of 300 diameters or more, minute particles of the copper wire are discovered adhering to the cover of the fuse plug, and, when a common visiting card is used for a cover instead of the mica, a decided deposit is attained. Repeated charges of such a fuse result in a complete coating of the card. When this surface is burnished with some smooth, hard object, a shiny polished metal surface results.

A fuse used in this manner is, in effect, a gun which throws out a shower of miniature shot so small as to be invisible to the naked eye, and this would operate successfully for covering almost any surface but for the annoyance of the frequent replacements with short pieces of copper wire. This led naturally to the development of a special "gun," into the barrel of which a copper wire is continuously fed. A pair of small rollers actuated by a motor pulls the wire off the supply spool and projects it across the barrel until the end touches the opposite surface. The inner lining of the barrel and the propelling rollers form a short circuit. The wire is immediately melted, and the heat causes it to be thrown out of the barrel against any object held in position for that purpose.

When a plurality of wires or a flat ribbon is used in order to cover a larger area in a given time, it is found desirable to add a propelling force, and this is done by introducing into the barrel behind the wire a small charge of explosive gas. The melting of the wire explodes the charge which projects the miniature metallic particles that are momentarily suspended in the gas against the object to be coated. It has been found that objects in great variety can be coated in this manner, and that any electrically conductive material can be used for the purpose.

ELECTRO-PLATING WITH COBALT

THE results of recent tests in electroplating with cobalt are summarized as follows:—Cobalt plating has a beautiful bluish-white color. The deposit does not tarnish as readily as nickel; it is homogeneous, with a fine, close grain; it is smooth and not brittle, and will easily withstand bending tests. The time required in order to secure a satisfactory deposit is much less with cobalt than with nickel. Metallic cobalt costs more than nickel, but the cost of the salts is of small importance in a comparison of the two as to economy in results.

Because of the greater conductivity of cobalt as compared with nickel, a current of higher density may be used in combination with a solution of less concentration. The time required in the solution with cobalt is one-third that required for nickel, and there is a similar saving of time in the buffing-room.

It seems to be thought necessary in some plants to have long lists of arbitrary rules for the government of employees. As conditions and the character of the workmen vary so much, it is difficult to say how far the matter should be carried. I believe that rules should be as few and simple as is consistent with necessary discipline. The personality of the foreman carries much more weight than rules.

Sheet Metal Elbows: Their Development and Laying Off-II

By J. W. Ross

In order to thoroughly understand the principles involved in the development of cylindrical and other forms, such as are met in sheet metal work, a considerable knowledge of geometry is desirable. Through the medium of these articles, the author places practical examples at the disposal of our readers, and the knowledge to be gained by a close and persistent study of the principles and methods employed will well repay the time spent.

THREE-COURSE ELBOW OF 90 DEGREES

FIG. 10 shows the elevation and cross sectional views of a three-course elbow of 90 degrees. In making these, no matter to what angle of a circle the elbow conforms, it is not necessary to draw out the full elevation view, as has been done here for explanatory purposes. Enough information for constructive purposes can be obtained by calculating the first mitre line and drawing this to the necessary measurements.

To calculate this mitre line, it is the practice to count each end course as one and the intermediate course or courses as two each. The sum of these is divided into the number of degrees of the elbow, the result being the angle of the mitre line. For instance, in the elbow of 90 degrees, as shown in Fig. 10, the courses I and III are each counted as one, the intermediate course as two, the sum being 4. Now, 90 degrees divided by 4 equals 22½ degrees, thus the mitre line BJO is drawn at an angle of 22½ degrees with AO, and the construction ABJK proceeded with.

For the benefit of the student the whole of the elbow will be drawn. As he becomes familiar with elbows he will find it much quicker to work from the calculation of the mitre line just described.

In Fig. 10, measure off AK equal to 1½ inches and KO to 2 inches. With O as centre and radii OK and OA, strike the quadrants KF and AE. Draw EFO at right angles to AKO. As this is a 90-degree elbow and of three courses, then each end course will be counted as one and the centre course as two, which will equal 4. Now divide the quadrant AE into four equal parts. Through these points draw a straight line from O, thus locating the lines OB, OC, and OD, and dividing the angle of 90 degrees into four parts of 22½ degrees each, this being 22½ degrees each for the courses I and III and 45 degrees for the course II.

At right angles to AK draw in the lines AB and KJ, intersecting the mitre line BJ. Similarly draw at right angles to EF the lines DE and GF to the mitre line DG. Connect B to D by a straight line, which will be tangent to the quadrant AE through the point C. Also connect J to G by a straight line. On this construction the outline of the elevation of the elbow is shown as ABCDEFGHJK, Fig. 10. The sections ABJK, BCHJ, CDGH and DEFG are all equal, the first forming No. I. course, and the second and third sections No. II. course, while the last section forms No. III. course, the reason being readily seen why each end course is counted as one, and intermediate courses as two. Obviously if the complete templet is laid out for course I., it will also be a complete templet for course III and a half templet for course II.

Construct the ½ sectional view A4K, using 4^1 as centre and 4^1A as radius. Divide into the desired number of equal spaces. A4K has six equal spaces, and are numbered as 1, 2, 3, 4, 5, 6, 7. These points are projected up to the mitre line BJ, all the lines being drawn at right angles to AK and parallel to AB and KJ. The intersections of these lines on the mitre line are numbered in relation to their divisions on the semi-circle, as

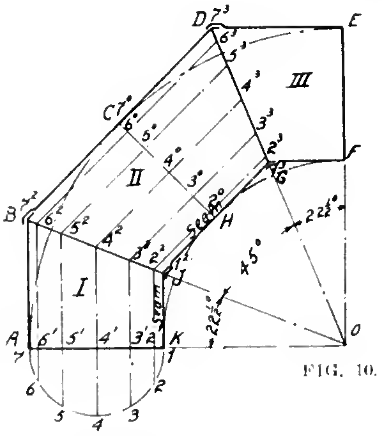

FIG. 10.

shown on the mitre line by the numbers, 7^2, 6^2, 5^2, 4^2, 3^2, 2^2, 1^2. From these points draw in the lines 6^26^3, 5^25^3, etc., parallel to the lines BD and JG.

Measure off the stretchout HCH, Fig. 11, equal to the stretchout of the neutral diameter AK or CH, Fig. 10. This equals 1½×3.14, which is nearly 4¾ inches. HCH, Fig. 11, is measured off 4¾ inches, and divided into 12 equal spaces, which is twice the spaces in the ½ sectional view A4K, Fig. 10. Parallel perpendiculars are drawn to HCH through these located points shown as $1^31^01^2$, $2^32^02^2$, $3^33^03^2$, etc. Set the dividers to the distances 7^07^3, or 7^07^2, Fig. 10, which are equal, and transfer over to 7^07^3 and 7^07^2, Fig. 11. Reset the dividers to the distance 6^06^3 and 6^06^2, Fig. 10, also transfer over to Fig. 11. Similarly transfer over the remainder of the distances on Fig. 10 to their allocated positions on Fig. 11.

An even curve drawn through these located points defines the rivet or mitre line. If suitable, these intersecting points may be used for rivet pitch centres, laps being added accordingly. JGDGJBJ, Fig. 11, shows the complete templet—with rivet holes and laps—for the course No. II., Fig. 10. The templets for the courses I. and II. are shown by drawing a line through HCH, Fig. 11, thus halving the templet, each half being the templet for either course.

It will be seen, as previously pointed out, that all the construction lines for the pattern can be obtained from the first calculated mitre line, as BJ, Fig. 10, thus obtaining the pattern for courses I. and III. and the half pattern for course II. It will be also noticed that in the preceding problems the vertical or longitudinal seams of the courses are placed on the inside throat of the elbow, as FE, ED, Fig. 1; LKJ, Fig. 3; CFE, Fig. 5;

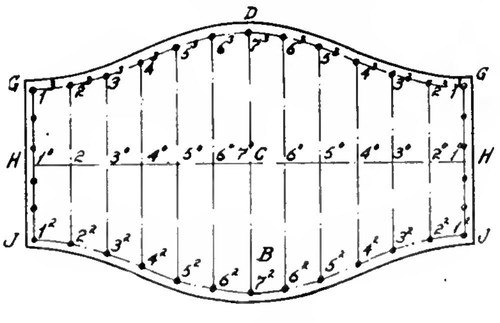

FIG. 11.

and also KJ of course I.; JG, course II.; CF, course III., of Fig. 10. This is the usual practice in the lighter gauges of plate.

In the heavier gauges the seams are generally placed on the centre line of the elevation view, as shown in Fig. 12, also in Fig. 14, the seam of alternate courses being in line, whilst the seam of the adjacent courses are diametrically opposite. The seams being placed at these points, naturally change the contour of the templet usual to the preceding problems.

Of course, if the preceding problems are made in the heavy gauges, it would be better to locate the seams, as will be described in the following problems.

Elbow With Inner and Outer Courses

Fig. 12 shows the elevation and cross sectional view of a cylindrical three-

course 90-degree elbow of heavier plate, with inner and outer courses.

In Fig. 10 and in preceding problems on elbows of light plate, the diameters of the courses were the same throughout in each elbow. This necessitated, for fitting up purposes, that the girth seam of a course should be slightly opened out by machine or by hand methods, so that it would fit over its adjacent course. In the heavier gauges this would be inadvisable, and to overcome this, elbows are made with inner and outer as well as telescopic or clinker courses. Fig. 12 shows an elbow constructed with the in and out courses, showing the thickness of the material for explanatory purposes.

Draw AK, Fig. 12, equal to the outside diameter of the elbow, thus showing the thickness of the plate. The inside diameter is 18 inches, the plate being 1/4-inch thick; the outside diameter will be 18½ inches, and the neutral diameter 18¼ inches.

Measure KO equal to 24 inches. These

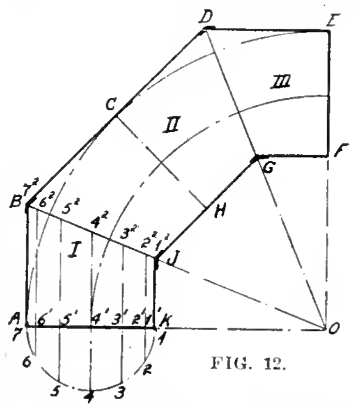

FIG. 12.

measurements may be reduced to scale for paper practice, say, 1 into 1 foot. With O as centre and OA as radius—A being the point located as the inside of the elbow—strike the quadrant AE. Similarly with O as centre and OK as radius, strike the quadrant KF. Thus the inside diameter of these quadrants will represent the inside diameter of the elbow.

As this is a three-course elbow, divide the quadrant AE into four equal parts, as A to B, B to C, C to D, and D to E. Through these points draw straight lines from O, thus locating the mitre lines BO and DO of the elbow. At right angles to AK draw up the lines indicating the thickness of the plate to the mitre line BJ, as AB and KJ. As EFO is at right angles to AKO, draw in the lines DE and GF at right angles to EF.

The intermediate course is an outer one: therefore, draw in the thickness of the plate, as shown, BCD and JHG. Locate the neutral diameter 71, and with 4^1 as centre and 4^17 as radius, strike the neutral half plan view 741. Divide this semi-circle into six equal parts and number as 7, 6, 5, 4, 3, 2, 1. Draw the projection lines 66^16^2, 55^15^2, etc., parallel to the lines AB, JK. The longitudinal seam for this course is located at 4^14^2. The girth seam at BJ.

The neutral diameter of the elbow is 18¼ inches; the stretchout will equal 18¼, multiplied by 3.14, or 3 1-7, which equal 57 5-16 inches along the line SAKS, Fig. 12A. Divide this into twelve equal parts, erect perpendiculars through these points and number as shown, care being observed to locate the vertical seams in their correct positions, 4^14^2, 4^14^2, at the lines SS, SS. Set the dividers to the distances 7^17^2, 6^16^2, 5^15^2, etc., Fig. 12, and transfer over to their relative positions on Fig. 12A. Draw in an even curve through these points for the rivet line, each point also being a rivet centre.

For ¼-inch plate the rivet will be ½-inch diameter, and the holes through the

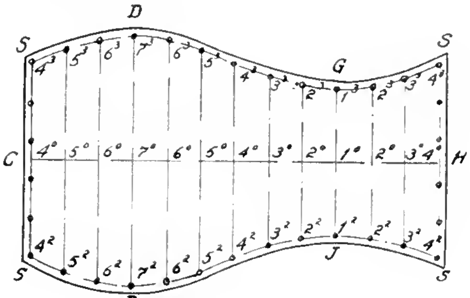

FIG. 13.

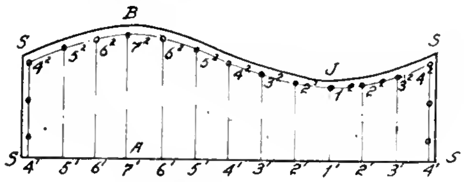

FIG. 12A.

plate 9-16-inch diameter. A suitable lap for this pattern will be twice the diameter of the rivet hole, which equals $2 \times 9\text{-}16 = 1\frac{1}{8}$, this being measured from the rivet line.

Fig. 12A shows the completed templet for courses I. and III. The development for course II. is similar, with the exception that its stretchout is longer than the stretchout of course II.

When one course fits over another, the stretchout is based on whether a tight, easy or slack fit is required, according to the nature of the work. In a previous article it was explained that for good steam-tight work the outer course would be made longer by an amount equal to 6.2 times the thickness of the plate. For an easy fit 6½ times, and for a slack fit 7 times, is used for easy, quick and economical assembling of the parts.

The course I. equals 57 5-16; therefore, the stretchout of course II. will equal $57\ 5\text{-}16 + (7 \times \frac{1}{4}) = 58\ 1\text{-}16$ in. Mark off CH, Fig. 13, equal to 58 1-16 inches. Divide into twelve equal spaces and erect perpendiculars. Number each point accordingly, so that when rolled up the longitudinal seam will be located at the centre of the elevation view similar to course 1, but diametrically opposite. Transfer the distances from course I. to each side of CH, Fig. 13, as shown. Draw in the curve of rivet lap, locate the holes and add on the laps. Divide the rivet lines SS, SS into the same number of equal spaces for the rivet centres.

METALS USED IN MAKING SHELLS

THE metals needed to execute the war orders already placed are estimated at over 10 per cent. of the 1914 copper production of the United States, about 7 per cent. of the spelter output and nearly 20 per cent. of the lead production, says the London Iron and Coal Trades Review.

A British 18-pounder, or 3.3-in. shrapnel, requires 5 lb. 9⅛ oz. of brass containing 66 to 70 per cent. copper, or nearly 3¾ lb. A small copper band around the shell adds 4¾ oz., making the total copper 4.04 lb.

Spelter consumption for a shell of this size is about 1.87 lb.

Lead bullets weighing 7.92 lb. and composed of 7 parts lead to 1 part antimony, constitute the metal load of the projectile.

Estimating the total orders for shrapnel and other shells placed in the United States by Europe at 25,000,000 they would call for a total of 101,000,000 lb. of copper, 46,750,000 lb. of spelter and 173,250,000 lb. of lead. Actually the metal consumption is larger, as a fair proportion of the shells are 4.5-in. howitzer shells using more brass; some 6-in., 7½-in., and probably 9-in. shells are also being made.

Rifle cartridges are made of copper mainly, 1 lb. of it being used in making 24 Lebel cartridges, a type widely used by the French army. Every 125 of these take 1 lb. of spelter and a small amount of nickel.

Steel consumption per shell varies widely in different types. A finished 3.3-in. shell contains 6 lb. 15¼ oz. of steel, the shell weighing 6 lb. 5¾ oz. and the diaphragm 9½ oz. If the shell is made from a steel bar, the weight is about 17 lb., while a forging for the same purpose weighs approximately 14½ lb. and a bottle made by the seamless tube process somewhat less.

Evolution of the Periscope.—The first submarine periscope was invented in 1854 by Marie Davy, but nothing very practical was designed till about forty years later. Mangin's periscope consisted of a ring-shaped mirror which enabled the horizon all around to be viewed. The picture was reflected downwards through the tube, but it was very small and distorted.

Machine Shop Production of 9.2" High Explosive Shells

In view of the fact that the manufacture of high explosive shells of sizes probably up to and including 12 inches diameter is likely to be undertaken at an early date in Canada, the following data relative to the machining operations on the 9.2 size will doubtless prove both interesting and instructive. We are indebted to Alfred Herbert, Ltd., Coventry, England, for the text and illustrations which give a fair idea of the work involved.

TWO alternative designs of 9.2-inch high explosive shells have been issued. The first, Mark IV/L, is a "closed in" shell of conventional type, while the alternative design, Mark II/L, has a screwed-in base plug similar to the larger naval shells. The latter design enables "block filling" to be used, and as this is now becoming practically universal, it would appear that the Mark IV/L shell will not be used very extensively and need not, therefore, be discussed meantime.

The forging for the Mark II/L body is made with the nose end closed, the bore is forged fairly close to size, and the outside has a generous machining allowance to take care of eccentricity in the bore of the forging. Alfred Herbert Co. have given much consideration to the machining processes of this shell, and have in course of manufacture machine tools designed specially to secure its quality and quantity production.

An outline sequence of the operations is shown in the line drawing (Fig. 1), the shaded portions indicating the work done at each handling. Before commencing machining operations, the nose end of the forging should be roughly squared up with a fettling wheel, to present a fairly true surface for starting the drill, in second operation.

Operation 1.—The cutting off is done on an ordinary engine lathe of suitable size, fitted with a bell chuck and a revolving steady in the tailstock for supporting the forging. In cutting off, the position of the tool should be carefully measured from the inside of the forging, so as not to leave an excessive amount of metal for removing from the bottom end of the bore.

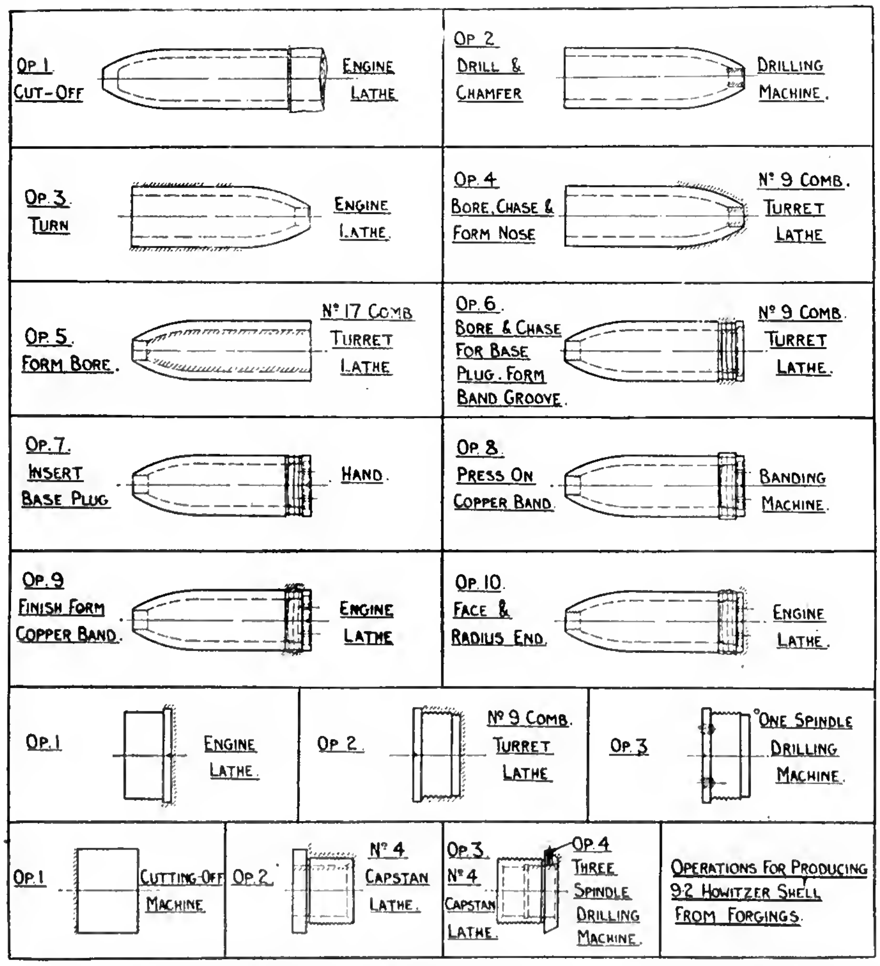

FIG. 1. SHOWING SEQUENCE OF MACHINING OPERATIONS ON 9.2 IN. MARK II/L HIGH EXPLOSIVE HOWITZER SHELL BODIES, BASES AND NOSE BUSHES. THE HATCHED PORTIONS SHOW WHERE MACHINED AT EACH OPERATION.

Operation 2.—The forging is next chucked on a special fixture on a heavy vertical drilling machine, the fixture being of a type which centralizes the forging from the rough bore. A 2¼-in. hole is drilled through the nose and the mouth of the hole coned.

Operation 3.—This consists of rough and finish turning the parallel part of the outside diameter, and is done on an engine lathe. The shell is gripped at the open end by the inside, so as to ensure the rough bore running true, while a running centre fitting in the hole drilled at second operation supports the nose end. Multiple turning tool holders can be used, reducing thereby the turning time considerably.

Operation 4.—Profile turning the nose, finish boring the nose, and threading constitute the fourth operation. This is being done on a simplified "Herbert" No. 9 combination turret lathe, the special equipment of which consists of a bell chuck for gripping by the open end, and a three-point steady. The machine is fitted with a special profile turning attachment, while the screwing is done with a patent chasing saddle. The whole of the machining at this operation is done from the cross slide, therefore the hexagon turret and the quick power traverse are entirely omitted, simplifying the machine considerably.

Operation 5.—This consists of boring the parallel and profiled interior. The machine for this operation is shown in the line drawing (Fig. 2), and is a special turret lathe adapted to the work of shell boring. The headstock has a two-step cone for 6½-in. belt and duplex back gearing. With a two-speed countershaft, 12 spindle speeds are available. The bed length gives sufficient travel for the turret slide, and provides a base for carrying the support for the formers.

The turret slide is of a special form and carries a special turret. The base of the turret forms a circular turntable located in a recess in the slide, and held down by a circular gib. The upper part of the turret consists of two massive bosses with loose caps, which form a long support for the boring bar, in which it can be securely clamped by four nuts. The turret slide carries an indexing bolt arranged to lock the turret in either of two stations 180° apart, and the turret can, in addition, be solidly clamped to the slide by two clamping pads. These are for use with double-ended boring bars not controlled by a former, which

would thus enable the machine to be used for boring Mark IV/L shell if required.

When using former controlled boring bars, the indexing bolt is disengaged, and the turret left free to rotate under the influence of the former slide. The turret slide has an apron of the standard type, and is provided with the usual quick power traverse motion along the bed. There are two automatic and dead stops for the two stations of the turret, which operate when the motion of the turret is towards the headstock. The turret has six changes of reversible feed, by three-step cone, gear change in the apron, and reverse box. Pump and oil supply to the bar for each station of the turret are provided, arrangements being made for accommodating the varying angular positions of the turret when using former controlled bars.

The boring bar is made of steel, and in a bracket at the tail end is carried the tracer roller, which engages with the former. Provision is made for putting on the cut from this end of the boring bar, which thus enables cuts to be started at the nose end of the shell, the turret traversing away from the headstock. This is an advantage, as the chips are more easily carried out of the bore.

A bracket attached to the bed of the machine supports the boring bar rigidly under the cut, and can be easily moved out of the way for taking the shell out of the chuck. The chuck used is of a simple design, and the outward end of the shell is supported in a three-point steady.

Operation 6.—This consists of boring the thread to receive the base plug, counterboring the end, forming the band groove, and the waved ribs. It is done on a combination turret lathe, similar to that used for the fourth operation, except that the profile attachment is not included. The boring, chasing and forming of the band grooves are all done from the square turret, the waving being done from the back of the cross slide by a special slide operated by a former cam, which is attached to the shell itself. The shell is chucked as in the fifth operation.

Operation 7.—This consists of screwing in and fixing the base plug (the machining of which is described later): being a hand operation, it needs no comment.

Operation 8.—The copper band is pressed on by any suitable type of press which may be available.

Operation 9.—The forming of the band is done on engine lathes, the chucking being done by a screwed peg fitted in the nose of the shell, which is locked up by a coned lock nut. The base end may be supported either by a dead centre in the base plug or else by running in a three-point steady on the outside diameter. The latter is probably the better method, as it ensures concentricity between the band and the body of the shell.

Owing to the rather complicated form of the band, a number of tools are required, and these may be carried in a suitable holder, each tool being successively applied to the work, being positioned by suitable stops.

Operation 10.—This consists of facing off the base plug in position, and forming the radius on the end. The operation is performed on an engine lathe,, the method of chucking being the same as in the ninth operation.

The Base Plug

Operation 1.—The forging is held in a three-jaw chuck on an engine lathe, and the 7-in. diameter is turned, faced and centred.

Operation 2.—This is performed on a combination turret lathe, similar to that used on the body in the sixth operation. The threads are rapidly cut with a patent chasing saddle, separate rough and finish chasers being used.

Operation 3.—The two tommy holes are drilled on a single spindle ball bearing drilling machine, the jig used being of simple design.

The Nose Bush

Although it is permissible to form the nose bush solid with the shell body, we consider it better practice, on a shell of this size, to make a separate nose bush, as it enables a stronger boring bar to be used for the fifth operation on the shell body.

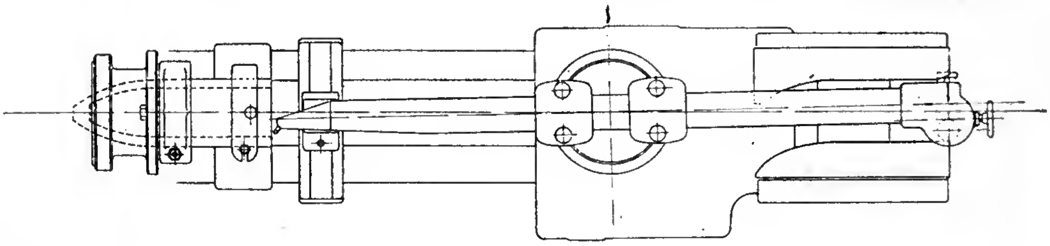
Operation 1.—The blanks are cut off to length on any type of cutting-off machine.

Operation 2.—This is done on a No. 4 capstan lathe, the external thread diameter being turned and chased, and the 1.9-in. hole drilled, bored and coned.

Operation 3.—This is also done on a No. 4 capstan lathe, the bush being held in a special chuck and drawing back by the external thread. The 2-in. thread diameter is finish-bored, recessed and chased, and the outside diameter formed.

Operation 4.—This consists of drilling the hole for the fixing screw, and is done on a three-spindle ball bearing drilling machine, the tools being of a simple design, and calling for no comment.

Sometimes a machine screw breaks off, and then if you don't know just how to remove it you're up against it. Next time this happens go at it in this way: Take a small square chisel and sharpen it to a point. Then drill a small hole in the machine screw you want to take out. Insert the point of the chisel in the hole in the screw and strike the blunt end of the chisel a pretty good blow with a hammer. After that it will be an easy matter, by using a wrench, to turn the screw out.



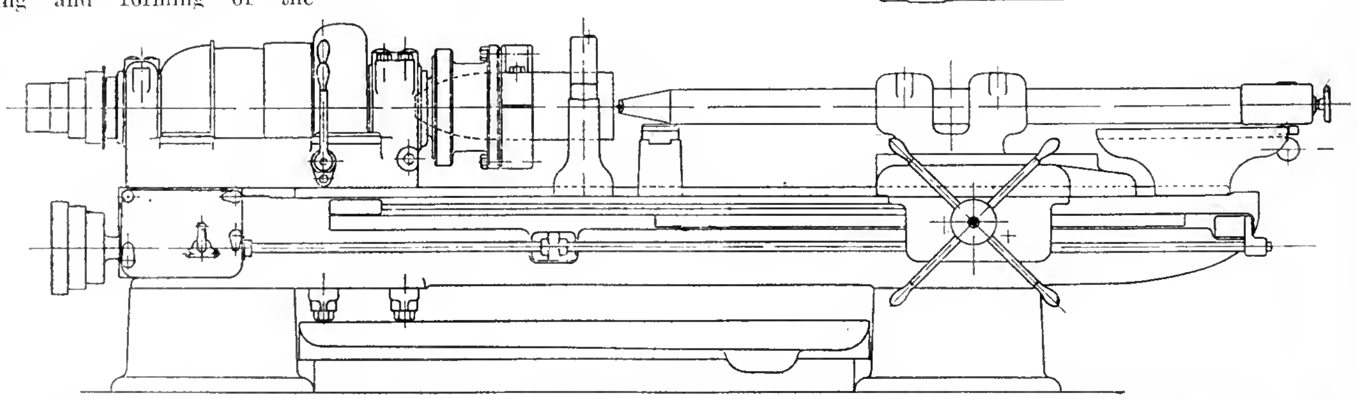


FIG. 2. OUTLINE DRAWING OF SPECIAL LATHE FOR BORING 9.2 IN. HIGH EXPLOSIVE HOWITZER SHELL BODIES.

THREADING DIES AND PIPE-CUTTING TOOLS

By J. E. H.

THE article under the above heading by P. W. Blair in the August issue of The Power House is all right so far as it goes. I wish to differ with him on one point, however. With reference to securing good threads, he writes, "The whole secret lies in the proper care taken of the tools and the lubricant used." The lubricant and care used are certainly important points in connection with threading tools, but the proper design of the die or chasers is much more so. Mr. Blair draws attention to several important matters but does not give the information necessary for their proper appreciation. I have had some experience along this line and will endeavor to place the matter before your readers in greater detail.

Getting Good Results

To get good results in threading at one cut the experience of the National Tube Co. shows that a die should have a suitable number of chasers, the approximate number being determined by the size of the die.

Machine or adjustable hand stocks and dies for $\frac{1}{4}$-inch up to $1\frac{1}{4}$ inches should have at least 4 chasers; $1\frac{1}{2}$ in to 4 in. should have approximately 6 chasers; $4\frac{1}{2}$ in. to 8 in., say 8 chasers; 9 in. to 12 in., say 12 chasers; 12 in. to 16 in., say 14 chasers, and 17 in. to 20 in., say 16 chasers.

Some readers of this journal may not agree with the above table, but in practice the results obtained have been the best possible after numerous tests. The experience of pipe manufacturers and others who do their own threading by machinery, shows that steel and iron pipe can be threaded equally rapidly and efficiently when the proper form of die is used, and the same may be said for properly designed dies used in ordinary hand stocks.

In order to obtain good results in threading any metal, the die must be made to cut and the pushing effect must be avoided. A chaser which pushes the material off, instead of cutting it freely, causes the threads to break out of the die. A die should be made with the proper consideration for the following points: Lip, chip space, clearance, lead or throat, and sufficient number of chasers.

Lip

This is also known as hook or rake, and is the inclination of the cutting edge of the chaser to the surface of the pipe, as shown diagrammatically in Figs. 1 and 2. This effect may be secured by milling the cutting face of the chaser, or by inclining the latter. The lip angle should be from 15 to 25 degrees, depending upon the style and condition of the chasers and chaser-holders.

Fig. 1 shows a chaser properly lipped for cutting ordinary steel pipe, the unbroken line showing how the lip should be ground. Care should be taken when sharpening the face of the chaser to maintain a good cutting angle—shown by the dotted line. Grinding back the face of the chaser does no harm if properly done.

Fig. 2 shows a die lipped for cutting open-hearth steel pipe, which requires a long, easy lip on account of the tough character of the material; the angle should be about 25°.

Fig. 3 shows a form of commercial die which is unsuitable for properly threading steel or wrought iron pipe. The dotted line shows how the die is usually made, in spite of the fact that this plainly makes a duller cutting edge than when ground as shown by the full lines.

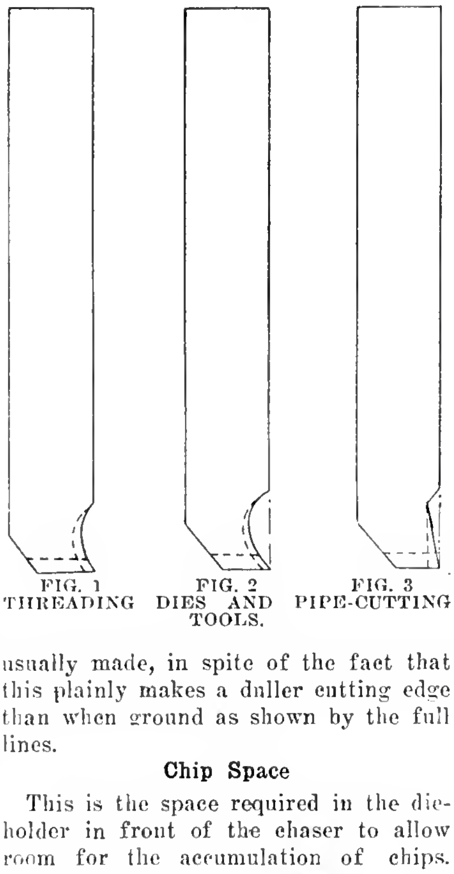

FIG. 1 FIG. 2 FIG. 3
THREADING DIES AND PIPE-CUTTING TOOLS.

Chip Space

This is the space required in the die-holder in front of the chaser to allow room for the accumulation of chips. "The importance of this feature cannot be too strongly emphasized," says the National Bulletin, "for if insufficient space be allowed, the chips will rapidly pack in front of the chaser and will soon begin to tear the thread." If the chip space is too small the die or chaser should project considerably beyond the ring.

Chip space is a particularly important consideration in dies used for cutting open-hearth steel pipe, as ample space is needed to care for the long, tough chips produced in threading this material. The lack of this feature in many commercial dies causes much of the difficulty often experienced in threading this class of pipe.

Clearance

This consists of the angle between the threads of the chasers and the threads of the pipe. When the chaser has been in use for some time, the sides of the threads become polished, brighter at the cutting edge, and gradually shading almost to their original color at the back. The chaser of a die which shows this condition will work freely, cut clean, will not tear the threads and will be durable. When the chasers of a die show a polish from the cutting edge to the back, there is a lack of clearance causing the cutting edge to work hard, heat, and make a rough, torn thread.

Lead or Throat

This is the angle which is machined or ground on the front of each chaser to enable the die to start on the pipe. The proper amount of lead is about three threads. As the heaviest cutting is done by the lead it should have a slightly greater clearance angle than the rest of the threads on the chaser. It should be noted that if the lead on only one chaser requires grinding to sharpen it, the whole set must be gone over in order to make the die cut evenly.

Lubricant

The best die made will not produce good results with poor oil. A lubricant particularly adapted to power machines where there is a steady flow of lubricant and which is also inexpensive, is composer of 30 per cent. cotton seed oil and 70 per cent. light neutral oil.

For hand tools, No. 1 lard oil may be used with success, as cottonseed oils have a tendency to gum up if the dies are not in constant service.

A die made by experienced tool makers with due regard to the points mentioned will thread wrought iron or steel pipe with good results. Much of the pipe on the market is steel, and it is naturally somewhat more difficult to thread with the old form of die.

In a paper by T. N. Thomson, read before the American Society of Heating and Ventilating Engineers, the author said: "The power required to thread mild steel pipe with a properly made die is not much more than that required to thread wrought iron with the same die, and much less than the power required to thread wrought iron pipe with a common die."

Executive ability can doubtless be cultivated by study and experience, but the man who has no natural talent in that direction, will never be a success as a foreman, superintendent or manager. Tact, or a knowledge of human nature, which enables one to treat each workman so as to bring out the best that is in him, is a very essential requirement.

Papers Read at the Recent Foundrymen's Convention

Selected from the more important subjects presented for discussion before the Annual Convention of the American Foundrymen's Association and the American Institute of Metals at Atlantic City, N.J., during September, 1915. The papers cover a wide field of foundry and allied activity, the nature of the results and the completeness of the reports making them of particular interest to all who desire to keep in touch with metallurgical progress.

MANUFACTURE AND USES OF WROUGHT MANGANESE BRONZE

Jesse L. Jones*

MANGANESE bronze when introduced into the United States from England about 1893, found its first important application in the manufacture of propeller blades because of its strength and toughness and the fact that it is practically incorrodible in sea water. The low melting point of the cast manganese bronze and the ease with which it can be cast into the most intricate forms lead to its adoption for many automobile parts and numerous other applications where service conditions are extremely severe.

The rolling and forging grades of manganese bronze had at first very few applications. The greater cheapness of the cast manganese bronze, its remarkable uniformity and excellence, and the fact that there was so little difference between it and the hot rolled grades as to physical characteristics, discouraged the use of wrought manganese bronze in many quarters.

As a rule, however, designing engineers consider forgings more reliable than castings, and they ascertained also that wrought manganese bronze has much greater strength and ductility than yellow brass, Muntz metal, Tobin bronze, etc. Hence forged manganese bronze began to be used in various water supply and irrigation projects. Forgings over three and three-quarters inches in diameter, more than twenty feet long and weighing over 900 lbs. have been successfully made. There is no record that any of these forgings have proved unsatisfactory or have failed in service.

Other applications are for piston rods, shafting, axles, etc., for machinery to be used in mines where there is corrosive water, or on shipboard for turret parts in connection with gun mounts, ordnance attachments, etc., where the metal must resist corrosion by sea water. A very soft, tough grade is used for sheet metal which has found application in the hulls of racing yachts, staybolts for locomotives and other bolts that must resist shock or the effect of repeated stresses. Extrufled manganese bronze blades have found some application in steam turbine construction where the erosive action of high-pressure steam is very severe. A large amount of wrought manganese bronze is used by powder and explosive manufacturers in situations where strength and non-corrosiveness is demanded, or where the use of steel would be dangerous by reason of its giving off sparks when struck.

Composition

Wrought manganese bronze differs chiefly from the casting grade in being free from aluminum. The addition of aluminum enables the alloy to be cast satisfactorily in sand molds. The following specifications as to composition may be considered as representative of the manganese bronze alloys most generally used:

Grade	No. 1A (for bars)	No. 1B (for sheets	No. 2 (for sand castings)
Aluminum ...	nil	nil	.15
Copper	57.35	58.15	56.00
Iron	1.40	.75	1.40
Lead	.03	.03	.03
Manganese ...	.02	.02	.12
Tin	1.20	.45	1.05
Zinc	40.00	40.60	41.25

Pure Metals Necessary

In order to secure ductility as well as high tensile strength, extreme purity of the materials used is absolutely essential.

The grade of copper used in England is known as "Best Selected." It is of good quality, except that it contains antimony and arsenic which harden and lower the ductility of any alloy in which the copper is used. In the United States, opinion as to which is the best grade of copper is somewhat divided. Non-arsenical Lake copper is usually preferred for particular work, because of its uniformity in quality, although the best grades of electrolytic copper are of equal analytical purity. The impurities usually present are as follows:

Copper Analysis.

	"Best selected"	"Lake"
Antimony	.019	nil
Arsenic	.023	nil
Copper	99.895	99.881
Copper suboxide	trace	.112
Iron	.056	.001
Lead	nil	trace
Silver	.007	.003
Sulphur	nil	trace

In the manufacture of manganese bronze the selection of a pure grade of zinc is perhaps more important than any other one consideration. Freedom from lead is essential, as lead oxidizes readily and makes drossy brittle metal. Absolutely pure zinc would be an ideal material, and while it can be and has been produced commercially, its high cost has militated against its use. Dr. Jos. W. Richards made several tons of electrolytic zinc a few years ago in Philadelphia, but no market could be found for it.

A very pure zinc is produced in Eastern Pennsylvania from a willemite or silicate of zinc ore. The concentrate used contains garnet, rhadocrosite, red oxide of zinc and Franklinite. The ore will average 49.26 per cent. zinc and 3.50 per cent. manganese. The slab zinc is marketed under various names, and it produces a manganeze bronze of remarkable strength and ductility.

A zinc of almost equal purity is produced by the double distillation of galvanizer's dross, the slabs being skimmed just before setting so as to remove any impurities that rise to the surface. While there is little difference in the analysis of zinc made from willemite and that made from dross the former has the greater toughness and strength. Perhaps this is due to the manganese in the ore. At any rate, if samples of the two grades of zinc of almost identical analysis are cast into slush molds, the one casting is liable to crack and the other will not. For this reason, makers of intricate slush zinc castings are compelled to use the willemite zinc. A number of the makers of high-grade zinc use the slush mold as a means of testing their product, and it will be found a very satisfactory way of testing zinc to be used for making manganese bronze.

The ordinary grades of spelter known as "Prime Western" are high in lead and for this reason should never be used. Scrap zinc reclaimed from sheet, etc., is also poor material. It may be high in lead and tin because of having been soldered, or it may contain much cadmium, which element has a hardening effect on manganese bronze. The grade of spelter used in England in conjunction with "Best Selected" copper is a French spelter known as Font-d'Art.

Melting

Crucibles are generally used for making forging manganese bronze, the heats being 325 lbs. each and requiring a No. 125 crucible. More recently there has been a tendency to use a No. 300 crucible as the smaller crucibles limit the output. Another reason for using the larger crucibles is that when a number of furnaces are attached to the same stack there are variations in the draft and it is seldom that any two crucibles can be brought out at the same temperature.

The copper is first melted, then superheated, keeping it carefully covered with

*Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa.

charcoal all the while. Next the iron and manganese additions are made from a small crucible in which they have been separately melted. Finally the zinc is added a little at a time with constant stirring and the alloy poured into ingots for melting. The remelting is considered necessary to secure a more uniform distribution of the iron and manganese. If the initial temperature of the copper is not high enough, or if the zinc is added too rapidly, the iron addition is thrown out of solution to a greater or less extent and is found disseminated through the ingots in the form of small shot which are practically high carbon tool steel. These shot will knock the edge from a machining tool in a few minutes and cause cracks in a forging when it is stressed. The composition of these shot is indicated below:

Aluminum	nil
Carbon, combined	4.34
Carbon, graphitic	.66
Copper	3.82
Iron	89.44
Manganese	trace
Phosphorus	.010
Silicon	trace
Sulphur	.020
Tin	.110
Zinc	.870

It is not difficult to obtain a uniform alloy, however, if due regard is had to the temperature of the copper. The copper must not only be hot, but very hot, as it is much easier to make bad metal by underheating than by overheating.

Where the ingot metal is remelted for pouring into slabs or billets, reverberatory furnaces can be used if intelligently handled.

The only entirely satisfactory method of melting manganese bronze is in the open-flame, oil-fired type of furnace. The melting loss is low, the additions can be thoroughly alloyed and the metal poled and worked so that remelting is entirely unnecessary and the metal can be poured into billets at once without the usual double melting loss. Large heats up to 20,000 lbs. can be made and the resulting economy is considerable.

Pouring

The removal of dross from manganese bronze that is poured into slabs may be accomplished by skimming the slabs just before the metal solidifies.

In making large ingots, a crucible with a hole in the bottom, may be set on top of the ingot mold, and by keeping the crucible partly filled with molten metal, the entrance of dross is prevented. When the metal is poured, there should be as little drop as possible, for a long drop results in forming much dross. Hence, ingots should be short and thick if possible. Bottom pouring would be a good thing, only it would give cold metal at the top of the ingot and result in the formation of long pipes. With care a discard of only 2 per cent. from the top of the ingots is possible. As the surface of the ingots is liable to be rough and full of cold-shuts, the ingots must be overhauled or rough turned before forging or rolling in oder to avoid blister or slivers in the finished product.

The pouring temperature of the bronze must not be too high or it will cut the molds and become contaminated in this way with cast iron.

In time the ingot molds become coated with a layer of metallic zinc mixed with zinc oxide which has sublimed from the red hot ingots and condensed on the face of the molds. Unless this deposit is removed by scraping the molds or heating them to a red heat in an annealing furnace, the quality of the ingot metal soon deteriorates. The zinc seems to diffuse through the ingot in a remarkable manner, possibly being deposited along the margins of the crystal grains in the form of metallic zinc and makes the bronze less ductile. At times, too, this layer of zinc on the mold will produce such a volume of zinc vapor when the bronze is poured that the ingot is full of blowholes.

Forging

Manganese bronze can be readily forged, drop-forged, rolled or extruded at a red heat. The physical characteristics will depend on the finishing temperature. The material hardens rapidly when worked cold, and machinery designed for the cold rolling and drawing of Tobin bronze, Muntz metal and yellow brass is not usually powerful enough to handle manganese bronze properly. This may result in the exterior of an article being overstrained while the interior is soft and comparatively unwrought. Excessive cold work on manganese bronze makes it glass hard and it may even become full of hair cracks and incipient fissures invisible to the eye, but capable of being shown by stressing. An infallible test for excessive cold work on material otherwise of good quality is the appearance of the fracture of a test piece. If cup-shaped or lipped like the fracture of a soft steel specimen, assurance may be had that the manganese bronze has been given the proper heat and forging treatment. If, however, the fracture is conchoidal and irregular, excessive cold work without proper annealing is indicated.

Other Grades of Forging Manganese Bronze

As the number of firms making manganese bronze has increased, there has been more or less competition for the business available and the quality of the metals used in the bronze has not always been as high as it should be. This has resulted in lessened ductility. Another cause for this fault is the desire for a higher tensile strength on the part of some designing engineers. To meet this demand, manufacturers have resorted to various plans which gave bronze of a higher tensile strength and elastic limit, but always with less ductility.

One manufacturer uses the casting grade of bronze, melts it in an open flame furnace and poles the metal until a part of the zinc is removed and much of the dross and dirt. This gives an extremely clean and tough metal for sand castings, but it is not especially suitable for forging, as there is always some entangled alumina in the bronze that cannot be removed and which may cause defects. Further, this grade of bronze hardens too rapidly when hammered and hair-cracks are nearly always present in the finished forging unless unusual care is observed.

Another maker uses one-half casting mixture and one-half forging mixture with the addition of a little extra manganese. A tensile strength of over 90,000 lbs. is thus secured, but the objections noted above hold good also for this mixture.

Other manufacturers have increased the aluminum by several per cent. or the manganese or both, and have made additions of vanadium, titanium, etc., obtaining in this way a tensile strength as high as 125,000 lbs. per square inch, but with an elongation that is seldom more than 20 per cent.

Any radical departure from the formulas given in the first part of this paper or the use of any but the purest materials can only result in inferior manganese bronze. Safety is not found in extremely high tensile strength, but in great ductility and in avoiding excessive cold working. A tensile strength of say 70,000 lbs. should not be exceeded. Great ductility allows more leeway in forging, but cold work is always objectionable, as it may result in hidden ruptures or later on in the so-called "season cracking." No manganese bronze, however ductile, in fact no wrought non-ferrous alloy whatever, can be said to be able to safely withstand excessive cold work that strains it above the elastic limit.

The future should see a more extended use of wrought manganese bronze. Its physical characteristics warrant a wider field for it. If those who manufacture it make quality the first consideration and if those who use it specify it intelligently, it will find a wide application.

Perhaps not always, but quite often, the skill of a machine operator can be measured by the condition of his machine.

The purpose of labor-saving machinery is generally to take the place of muscular effort; it is presumed the operator will always do the brain work.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

200 H.P. HIGH COMPRESSION OIL ENGINE

IN large sizes, the Nordberg Manufacturing Co., of Milwaukee, Wisconsin, builds Diesel engines of the "Carels Freres" type but for moderate sized units, namely, 50 to 200 horse-power. They build a high compression oil engine designed to meet the demand for an engine as simple as a slide valve steam engine.

The accompanying photographs illustrate the 200 horse-power 270 r.p.m. size, "Nordberg" high compression oil engine, also details of starting gear and fuel pumps. These engines resemble Diesel engines in so far as concerns the method of ignition by the heat of the highly compressed air. The compression pressures are about 450 lbs. A three-stage high pressure air compressor to register 1,000 lbs. is not used for injecting and atomizing the fuel. The fuel is injected mechanically by a small pump and discharges through a new type of atomizing head which successfully subdivides and atomizes the oil. The success of the engine is, we understand, due largely to the effective working of this atomizing head. (See Fig. 4.) The elimination of the high pressure compressor with its intercoolers simplifies the installation in small plants for which these engines are designed.

The engine is of the two-cycle design, and all valves, cams, springs and valve gear have been eliminated, contributing further to the item of simplicity and ease of attendance and inspection. The head is a simple symmetrical casting, and is not subject to cracks due to unequal expansion strains. There are no valves in the head. The only valve on the engine is a piston valve for scavenging air located above and between the cylinders in the 200 horse-power illustrated. One valve controls the scavenging air for the two cylinders. Air is

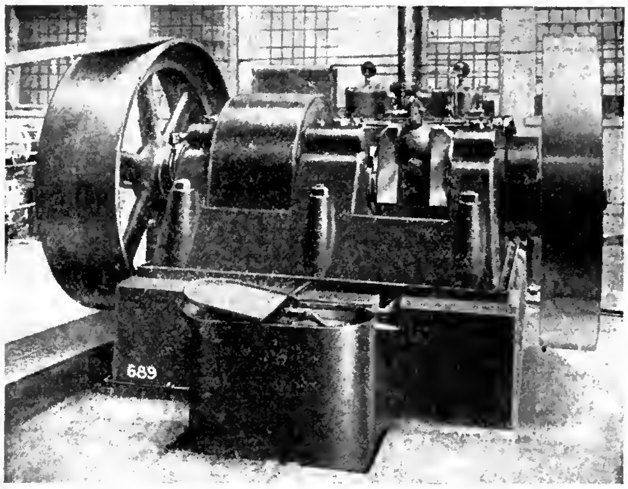

FIG. 2. "NORDBERG" 200 H.P. HIGH COMPRESSION OIL ENGINE WITH ONE CRANK CASE GUARD REMOVED.

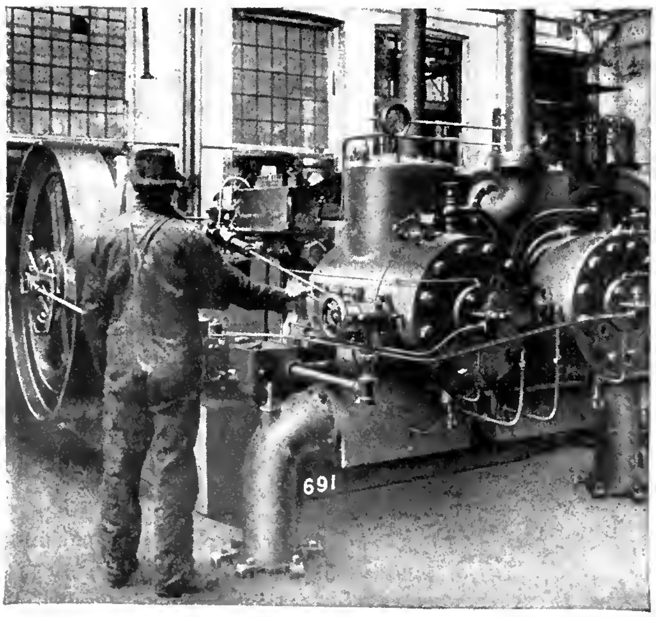

FIG. 3. STARTING "NORDBERG" 200 H.P. OIL ENGINE.

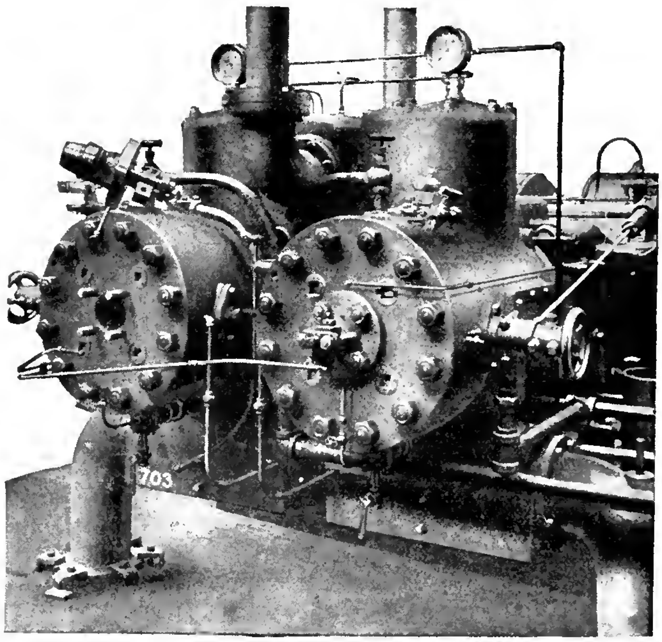

FIG. 4. CYLINDERS OF TWIN 200 H.P. OIL ENGINE.

compressed on the crank side of the piston and by-passed to the head end shortly after the uncovering of the exhaust valves. This forces the burnt gases out of the cylinder and fills it with fresh air. Compression and combustion then occur as in any two-cycle engine. The air intake is through the vertical pipes above the engine, and exhaust through the pipes going through the floor.

In the 200 h.p. twin engine, a special automatic starting arrangement has been designed simplifying the operation so that engine may be brought to speed in less than a minute.

Fig. 3 shows the operator starting the engine by rocking an air valve which turns the engine over and at the same time throws in two auxiliary air cams which thereafter admit air at the proper points in the stroke to each of the two cylinders. The starting air is furnished by a steel tank previously charged to 250 lbs. from a small auxiliary compressor. When the engine has come to speed, one of the cams is thrown out by the corresponding finger shown near the top of Fig. 5, and at the same time the corresponding fuel pump is thrown into action by one of two levers on the same side of the engine, which may also be seen in Fig. 5. As soon as this cylinder fires, the air cam for the other cylinder is thrown out and the second fuel pump thrown into gear. The engine is then under control of the governor.

Fig. 5 shows the details of the fuel pumps which run in a bath of lubricating oil, the fuel levers and fuel governing mechanism. The oil is drawn from the storage tank to a small strainer box located to the right and behind the pumps from which it flows to the main fuel pumps. A small heating coil, through which heated jacket water circulates, is contained in the main oil compartment of the strainer box to insure free flow of very viscous oils. The pumps are operated by cams driven by an eccentric and deliver a quantity of oil in excess of that required for maximum load, the governor acting to by-pass more or less of the fuel depending on the load obtaining.

The by-passed oil is discharged through the sight glass and gives the operator a quick check on the working of each of the pumps. The governor is of the well-known fly wheel design, and gives a regulation of 2 per cent. from no load to full load. From the fuel pumps the oil is discharged through small pipes to the atomizer heads bolted to the main cylinder heads, as shown in Fig. 3, and also in Fig. 4, where one atomizer head has been removed and placed on top of a cylinder. This device breaks up the fuel in fine particles and distributes it evenly over the entire section of the cylinder in the same manner as does the fuel valve using highly compressed air in Diesel engines.

The lubricating system of the engines is entirely automatic, oil being fed from a central pump driven from the scavenging valve eccentric, shown in Fig. 5. Cylinder oil is pumped to the scavenging air valve and to the main cylinders. Bearing oil is pumped to all main bearings, to the crosshead pins through trombone oilers and to all auxiliary bearings. The cranks are enclosed by polished iron guards, as shown in Fig. 2, and the oil accumulates in the crank case from various parts of the engine, and is drained to a filter and returned to the lubricator. Fig. 2 also shows the frame, bearing and crank construction in these twin engines.

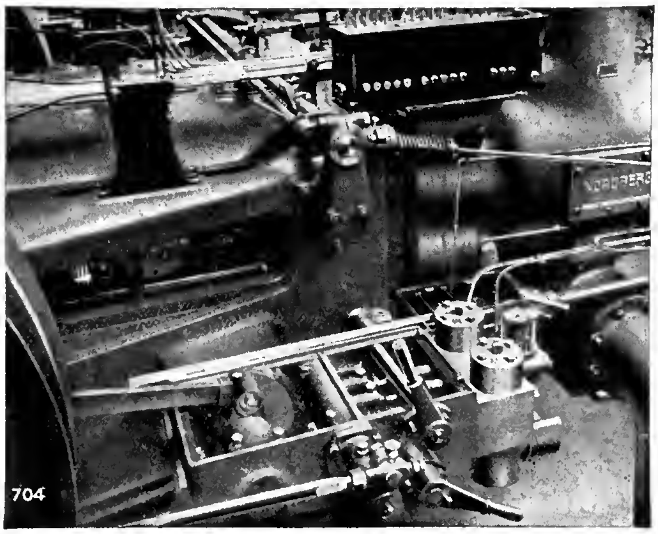

FIG. 5. VIEW OF FUEL INJECTION PUMPS, STRAINER TANK AND AIR STARTING GEAR OF "NORDBERG" OIL ENGINE.

The photographs of the engine shown herewith were taken in the Test Department of the Nordberg Manufacturing Co., where permanent concrete testing blocks have been installed for each of the three sizes of high compression oil engine built. Before shipment these engines are given routine tests for economy and mechanical troubles.

"LEA" V-NOTCH METER INTEGRATOR IMPROVEMENT

THE Yarnall-Waring Co. are placing on the market a new and more heavily designed integrator, for use on their well-known "Lea" V-notch recording liquid meter. Figure 1 shows the type which has been used for a number of years, and Figure 2 illustrates the new type.

In the new type, the aluminum dial which drives the integrator counter is in turn driven by means of a pendulum clock movement, built especially by the Seth Thomas Co. for this service. It has a double heavy spring pendulum movement, which is so constructed that vapor and dust do not seriously affect its accuracy.

It has been found advisable in practice to use a clock mechanism for the operation of the integrator separate from the clock mechanism which operates the chart recording mechanism, for the reason that if either clock should be deranged in service the user still has the other clock to depend upon. In addition to this advantage, one clock can be used as a check against the other, and more dependably accurate results be obtained.

The original "Lea" V-notch instruments were built with hand screws for making adjustments. It has been found, however, that in a few instances in power plant service vibration sometimes caused these thumb screws to loosen slightly. Hence, in the new model instrument heavy screws with slotted heads are employed for making adjustments. A screw driver only is needed for making such adjustments, and these when carefully made are found to be more secure than with the old type thumb screw.

In the new type instrument, the pen arm adjustment has been simplified, also the yoke supporting counter dial on the integrator. The case is so designed that the instrument cannot be affected in any

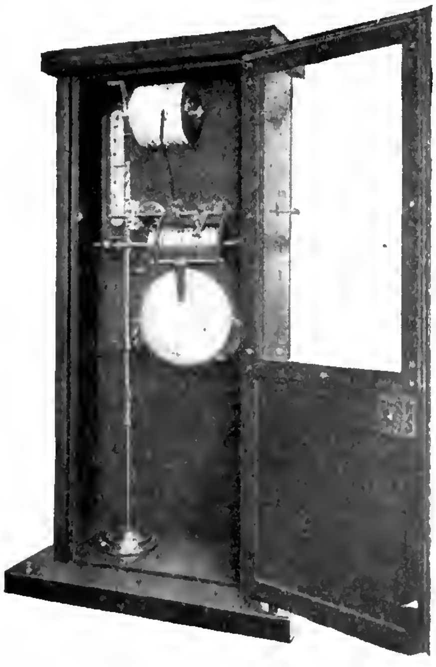

FIG. 1. ORIGINAL "LEA" V. NOTCH INTEGRATOR.

way by steam or vapor getting into the instrument case, nor even by serious vibration. The door of the case is equipped with a tongue entering a felt-lined groove and a three-way locking device

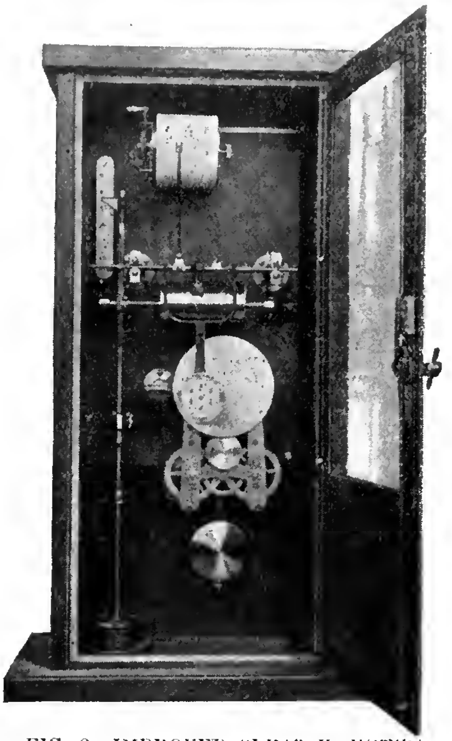

FIG. 2. IMPROVED "LEA" V. NOTCH INTEGRATOR.

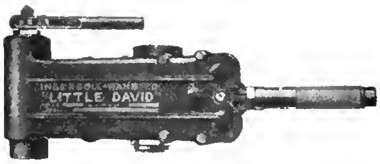
jams the door against the felt, making practically an air-tight joint. This is valuable, especially for an instrument which is sometimes set in damp or rusty boiler plants.

NEW PORTABLE "CLOSE QUARTER" DRILL

OF timely interest to those having portable drilling to do, whether in machine shop, boiler shop, foundry, in the field, on bridge construction, or general structural steel work, is a new pneumatic drill for close quarter drilling, reaming, tapping, etc. This tool shown in the accompanying illustration is a recent addition to the "Little David" line of pneumatic tools, manufactured by the Ingersoll-Rand Co., 11 Broadway, New York. It is particularly adapted for working in cramped or confined positions, where the regular type of four piston reciprocating pneumatic drill cannot be used, the distance from the end



CLOSE QUARTER PORTABLE DRILL.

of the casing to the centre of the spindle being only 1 5/16 inches.

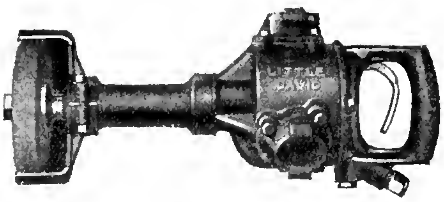
The motor is of a novel three-cylinder design and operates in a bath of oil. The valve is of the rotary type, and is gear driven from the pinion of a three-way crank shaft. This crank shaft is operated by the three ratchet levers which directly connect the pistons to the drill spindle.

An important feature of the machine is that there is practically no strain on the crank shaft, as the power is transmitted direct from the pistons through the levers to the ratchet spindle. The spindle has a triple ratchet, and a noteworthy feature is that one of the ratchets is engaged on the spindle at all times. This construction is claimed by the manufacturers to develop more power and give a more constant pull on the spindle. The casing is divided in such a way that the loosening of a few cap screws allows easy access to all moving parts.

The drill is fitted with a No. 4 "Morse" taper socket; is rotated for drilling up to 3 ins. and reaming and tapping to 2 ins., and operates at a speed of 150 r.p.m.

PORTABLE PNEUMATIC GRINDER

A NEW portable pneumatic grinding machine has recently been introduced by the Ingersoll-Rand Co., New York. The "Little David" grinder, as this tool has been named, has many novel features, and has been designed with special reference to simplicity and accessibility in all its parts. The motor is of the three-cylinder type. The connecting rods are of one-piece construction, fitted to the crank shaft on roller bearings. The crank shaft and spindle are combined



PORTABLE PNEUMATIC GRINDER.

into a solid piece drop forging, which runs on a triple ball bearing, one bearing being used in the front end of the main body of the casing and two bearing on the end of the spindle. All parts are enclosed in an absolutely dust-proof case and operate in a bath of oil.

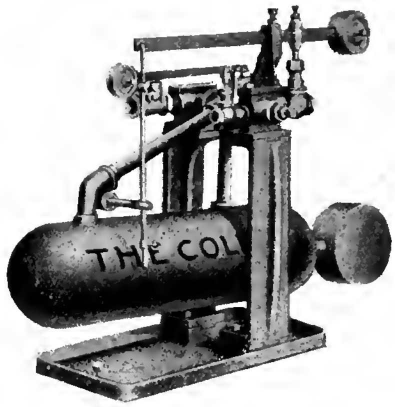
To lessen the complication of delicate parts, the valve construction of the rotating type is made a part of the crank shaft, and works in a renewable bronze bushing. No gears or pinions are used. The connections between the piston and connecting rods are of the same general design as those used in the maker's line of pneumatic drills.

The entire operating mechanism is readily accessible, the loosening of six cap screws removing the handle and exposing the entire interior for examination. The cylinders are renewable without renewing the main body of the casing, and are interchangeable. As may be seen from the illustration, the cylinders are provided with lugs, which take care of the wear on the exposed corners.

This grinder is rated to operate up to an 8 ins. diameter emery wheel at a speed of 3,400 r.p.m., and is specially designed for grinding, buffing, polishing or cleaning castings.

THE "COLE" LIFTING TRAP

THE George W. Cole Co., Toronto, Ont., has recently placed on the market a lifting trap designed to raise condensation from a low pressure heating system to a return trap or open



THE "COLE" LIFTING TRAP.

tank. This trap is also designed to remove condensation from steam systems which operate on very low pressures down to atmospheric or even below.

The accompanying illustration gives a general idea of the construction of the apparatus which is entirely different from the ordinary lifting or return trap in that it is turned upside down. By a special arrangement of levers and fulcrums, a full displacement in the receiving chamber is assured, there being a free escape of the air which usually collects in heating systems and is often a source of considerable trouble.

The trap is provided with self-adjusting packing glands which are readily accessible. It is specially suitable for a modulating type of heating system where the steam enters the top of the radiator and discharges through a swing check or similar type of valve.

If you have any old files around your shop that have apparently seen their best days try this: First clean them well with a fine wire brush and then give them a bath in diluted sulphuric acid. You will find that most of them will be almost as good as new after this treatment.

THE COMMERCIAL ASPECT OF MUNITIONS' PRODUCTION

RECENT events connected with the conduct of the war would seem to indicate the probability of an immediate change in the methods whereby the British Government may avail itself of the efforts of Canadian manufacturers.

Early in the war certain English textile mills were not inclined to devote all their efforts to war contracts, because of the interruption to their ordinary business. Whether such action was due to indifference or because regular business was more remunerative, does not really matter, but what really does matter is this: Lord Kitchener told these particular firms that their mills would be run on war contracts, if not by themselves, then by the Government. There was no question of a quid pro quo in the form of higher prices or something equivalent. These mills simply had to run on Government work, and they did run.

Since then numerous incidents have occurred which show that many people have not only failed to realize the absolute seriousness of the present struggle, but by their attitude and actions, betray a self interest and indifference, which, if exhibited a few thousand miles nearer the scene of hostilities, would be terminated rather promptly, if not abruptly.

For some considerable time Munitions Tribunals or Courts have been in existence in Britain, their principal sphere of activity being the trial and punishment of employees who are guilty of "slacking" or otherwise retarding the efforts of the nation. These Tribunals have been constituted for dealing with the labor end of the business, and their counterpart for dealing with the employers is found in the action of the Government, whereby factories are taken under control on stated terms, and the utmost possible use made of the plant and equipment. We use the word "possible" because until "slackers" are eliminated, a maximum output will not be obtained.

Owing to stress of circumstances no doubt, the proportion of union labor engaged in munitions manufacture is very much less in this country than in England, consequently, while attempts at slacking may have taken place in some isolated cases, their effect has not been sufficiently noticeable to demand attention.

The resolutions passed recently by certain trades unions affirming their loyalty and disavowing any attempts at restriction, etc., seem rather out of place at this late hour of the day, and in view of the inference which might be drawn, such action seems rather ill-advised. Be that as it may, it is safe to say there will be no necessity for any Munitions Tribunal in Canada.

It may be otherwise, however, as far as our factories administration is concerned. The organization of the Canadian Shell Committee, under the conditions which originally existed, has been repeatedly justified by the success of its efforts in the past. Changed conditions in Europe, and the certainty of a prolonged struggle with its attendant strain on Britain's resources should by this time, however, have prompted the responsible parties in this country to look upon the British Treasury as something better than a milch cow.

Few Canadian enterprises of national magnitude have enjoyed the glory of successful achievement without being accorded the doubtful honor of a commission of inquiry, and Canada's reputation as a loyal and efficient member of the British Empire would suffer immeasurably should the self-sacrifice and effort of the people as a whole be nullified in the slightest by the failure of men in high positions to realize that their main duty now is to the Empire and not to themselves.

Latent selfishness is more dangerous than active opposition, and should compulsion in the guise of controlled factories be brought about, many manufacturers will only have themselves to blame.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, Que., Oct. 25, 1915.—The demand for steel products still continues, a substantial advance in many specialties being one of features of the past week. While the demand for steel bars and billets for the production of munitions is admittedly the most insistent ,various other lines are also in strong request by metal working plants. The scarcity of supply of seamless tubing has started an upward trend in the quotations on this commodity.

Metals

Metals generally are holding firm and quotations show little change from the previous week. A few export inquiries have been received for copper, but the general dullness has a tendency to shade prices.

Tin remains firm at previous quotations.

Spelter shows some improvement, and producers are refusing to sell futures as freely as they were a week ago.

Quotations on lead are unchanged, the market showing a slight increase in activity. Antimony is being contracted for in considerable quantity for future delivery.

Machine Tools and Supplies

The situation as regards machine tools is unchanged. Delivery of long ordered equipment still lags and, of course, causes more or less inconvenience. In many cases, where it was impossible to secure the desired machinery, acceptance was made of tools that were considerably larger than those required for current needs. This may ultimately turn out to have its compensations, for, while fulfilling the present requirements, they may also supply those of the future if the opportunity offers of manufacturing larger shells than those now being produced.

Supplies naturally are also in active demand, with prices at least firm.

Sheets

The slight increase in the demand for galvanized sheets is keeping prices firm. The supply is considerably below normal; however, an improvement in this respect is anticipated in the near future.

Old Material

A steady improvement is shown in the demand for scrap metals, and, while prices are meantime little more than steady, indications point to an advance shortly, due to some mills requiring additional scrap sooner than they expected.

There is little demand for foundry scrap, and prices are weak.

Toronto, Ont., Oct. 26.—The general improvement in trade continues and an optimistic spirit prevails in business circles. The crops, which are an important factor in the development of this country, have been so bountiful this year that they will add materially to the wealth of the community generally and inspire a greater feeling of confidence in manufacturing circles. In addition, the large volume of war orders will contribute to place many of our industries on a very satisfactory basis. The trade returns for six months ending Sept. 30 are very encouraging. The figures show a satisfactory advance over the corresponding period of last year. The export of manufactured goods for September was very heavy, reaching a total of over nine million dollars compared with a total of a little over five millions for Sept., 1914. Imports also showed an improvement. The duties collected on imported goods show an increase of approximately one and one-half million dollars for the six months compared with the corresponding period of 1914.

> **CANADIAN GOVERNMENT PURCHASING COMMISSION**
>
> **The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.**

Developments in the shell industry are being awaited with the greatest interest. A new system of placing contracts for the large calibre shells will be introduced. Canadian manufacturers are being asked to submit tenders for 6-in., 8-in. and 9-in. shells, thus placing the business on a competitive basis. It is reported that orders amounting to $80,000,000 for the larger shells are about to be placed by the British Government through the Shell Committee.

Steel Market

A general advance in prices is the principal feature of the steel market this week; the heavy demand has had this natural effect. All indications point to a still heavier demand and also to higher quotations. Canadian mills have raised their quotations on iron and steel bars to $2.35 base per 100 lbs., representing an advance of 10c. Reinforcing bars are now quoted at $2.35 base. plus extras for twisting. Warehouse prices are higher in proportion. Pittsburgh bars, plates and small shapes for Canadian consumption are now being quoted at 1.40c and steel hoops at 1.60c, Pittsburgh.

Wire has advanced 15c and is now quoted at $2.75 base. Wire nails are up 10c and are quoted at $2.55 per keg. Quotations on proof coil chain and electric weld coil chain are higher. Prices on wrought iron pipe are very firm and are expected to advance any time. With the market in the present uncertain condition, prices are liable to fluctuate, and in some cases orders can only be accepted subject to immediate acceptance. The enormous demand for steel for munitions has been chiefly responsible for the present conditions in the market. Steel plants are working to capacity to meet the demand. and this will increase as the shell industry expands and as orders for domestic steel products increase in volume.

Prices of high-speed tool steel continue to advance and the situation is becoming more acute. The most serious feature is the difficulty of obtaining supplies in anything like the quantity required. The demand has practically doubled owing principally to the necessity of having high-speed tool steel for machining shells. Some producers have withdrawn from the market, while others are only able to supply their customers with comparatively small quantities. The scarcity of tungsten, which shows no improvement, is the cause of all the trouble. Other alloys have advanced in price, as have also the cost of crucibles, labor, etc.

The galvanized sheet market is quiet, there being only a moderate demand, but prices are being maintained. Black sheets are advancing and spelter is too high in price to create much interest among galvanizers. Bessemer black sheets have advanced $2 a ton, and No. 28 gauge are now being quoted at 2.10c Pittsburgh.

The heavy demand for steel products in the States continues, and prices of finished iron and steel are steadily advancing. There is no abatement in the heavy demand for large rounds for shell manufacture. and the steel mills are sold up for the remainder of the year. Prices of steel bars. plates and shapes have advanced to 1.45c Pittsburgh. There is a continued heavy demand for open-hearth and forging billets on which prices are very strong on the advance. Forging billets are now quoted at $34.50, open-hearth billets at $25 and Bessemer billets

From Illuminating Gas to Russian Shrapnel

A more complete transformation than that involved in changing from illuminating gas manufacture to shrapnel shell production would be difficult to imagine. That such a change has been made, quickly and successfully is additional assurance, if any be needed, of Canada's ability to adapt her industrial resources to any required line of activity.

Staff Article

ALTHOUGH much has been written and said about the manufacture of shells in connection with the British War Office contracts, comparatively little has become known regarding French and Russian shrapnel, large orders for which are now in course of execution in this country.

While the various types of shrapnel are more or less similar in their general features, there are some points of design in which considerable divergence is noticeable.

The Lachine Manufacturing Co. of Lachine, Que., was the first plant in Canada to undertake the production of Russian shrapnel. This firm, who had been for several years manufacturing illuminating gas for various purposes, some time ago commenced the manufacture of Russian 3-inch shrapnel shells. Operations were at once commenced and such good progress made, that within four months they were working on the semi-finished product. When it is considered that buildings had to be erected and every tool secured and installed, it makes the achievement all the more remarkable.

The Building

The building is of solid brick construction, 112 feet by 100 feet and 25 feet high, with structural steel mill roof, covered with 1½-inch planking. The floor is of solid concrete. The shop is well lighted from three sides and also by a large sky-light extending the full length of the building; artificial light is supplied by 44 nitrogen lamps, being one 250 e.p. light for every 250 sq. ft. of floor space.

The building, which is steam heated, was completed in 15 days, and the time of laying the concrete floor was 3 days.

A general view of the machine section is shown in Fig. 1, while Fig. 2 is a plan of the machine layout.

Trimming End and Centering

The first operation on the rough forging is sawing off the open end. This is done in 4 Racine Tool & Machine Co. high-speed metal cutting machines. The shells are then taken to a 15¼-inch Carrol-Jamieson lathe, placed on a mandrel held in the lathe spindle, and the base of the rough shell centered.

Rough Turning

The third operation, rough turning the outside diameter, is performed on a Butler 22-inch gap lathe; one C. M. C. 22-inch gap lathe; 2 R. McDougall lathes, 22 inch gap and 20 inch, and two Rahn-Larmon 20-inch lathes. The shells are placed on a fluted arbor and the outside diameter roughed off over the complete length.

Facing Base

Facing off the base is the fourth operation; this is done on a 30-in. x 30-in. x 10-ft. C. M. C. planer, as shown in Fig. 3. The capacity of the machine is 80 shells per load. The shells are set up in the jig, and base roughed off (leaving 1-16 inch surplus stock over finished dimensions) with both heads working, and the shells removed in one hour and a half, which gives a total of 530 shells in ten hours. The general design of the jig can be clearly seen by referring to Fig. 4. The jig A is secured to the planer table and the gauge studs B are screwed into the base and locked by the nut shown. The shells C are then placed on the studs and clamped firmly up in the vees of the jig by the clamps D.

Heat Treating

Tempering, annealing and scleroscope testing is the next operation. This is done in a room at the rear of the main building and the arrangement of the equipment is shown in Fig. 5. The two furnaces in the background are for hardening and tempering the shells, and were supplied by the Strong, Carlisle & Hammond Co. of Cleveland, Ohio.

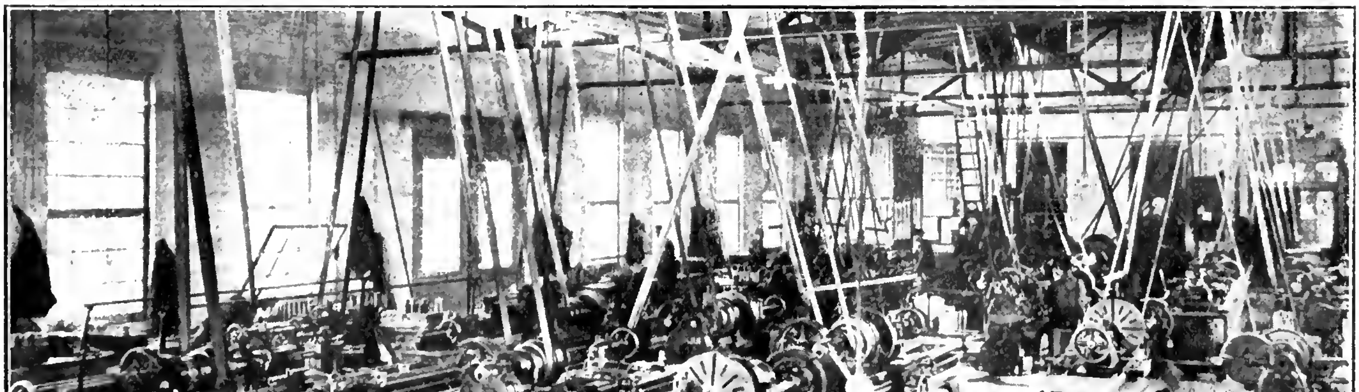

FIG. 1 GENERAL VIEW OF MACHINE SHOP

To the front of the hardening furnace is shown the quenching bath; the oil is kept in circulation by the pump shown at the top left-hand edge of the tank. The blower which supplies blast to the various furnaces is driven by a 10 h.p. motor, supplied by the Canadian Crocker-Wheeler Co. of St. Catharines. The furnace to the extreme right was installed for heating the nose in preparation to closing-in, but this was found unnecessary, as very satisfactory results could be obtained by closing the nose while cold.

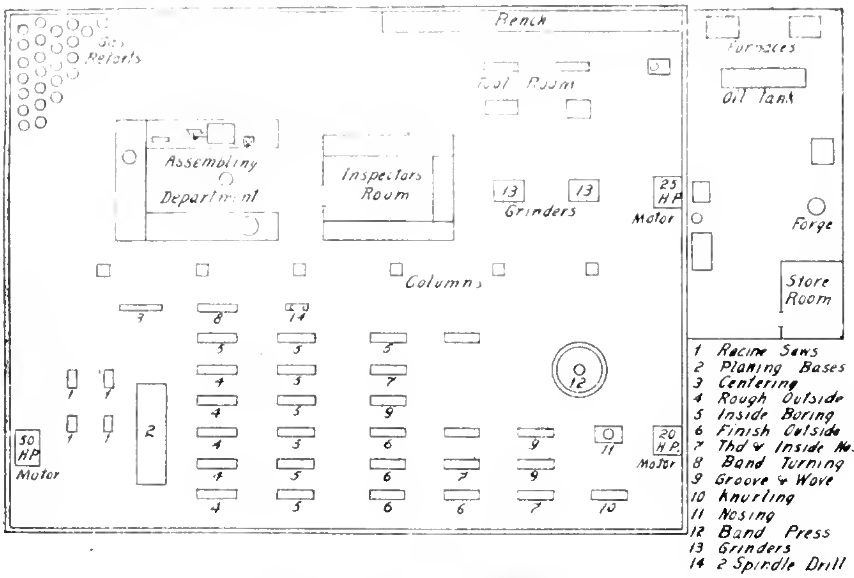

FIG. 2. LAYOUT OF MACHINES

Quenching Bath

A sketch of the quenching bath is shown in Fig. 6. Within the main tank A is placed the inner tank B which contains the oil for cooling the shells. This oil is kept in circulation by means of the pump E, which is driven from a shaft overhead. The oil is drawn up through the pipe F into the pump, and forced through the pipe G, and the coil H and into the tank again at the opening I. This water in the outer compartment A is also kept in continual circulation, entering from the feed pipe J and overflowing from the discharge pipe K.

Inside Boring

After the shells have been heat treated and tested for hardness they are taken to the 6th operation, which is boring and forming powder chamber and diaphragm seat. The lathes on this operation are one Rahn-Larmon, one Walcott and Wood, 3 Boyé and Emmes and one Walcott; all of these are 20-inch engine lathes fitted with special turrets designed and constructed in the shop. These special turrets, which are giving excellent satisfaction, are used on a large number of the engine lathes in the shop, as the work in this plant is being performed without the aid of any standard make of turret lathe or machine.

The cycle of operations at this stage is chucking, rough bore, rough powder chamber and diaphragm seat, finish diaphragm seat and face off open end, rough taper and finish taper. This operation of roughing and finishing the taper bore is performed by solid reamers as shown in Fig. 7.

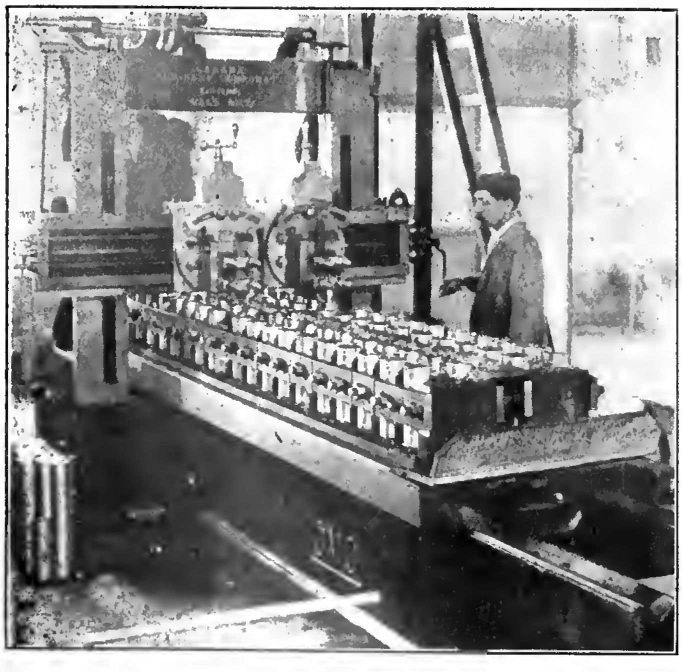

FIG. 3. FACING OFF BASES ON PLANER

Special Turret

Fig 8 shows a sketch of the special turret designed and constructed in the shop. The base A is secured in a central position on the lathe saddle; this base is recessed out to receive the revolving turret B, which is held in position by the ring C; this ring is secured to the base by the bolts D. In the bottom of the turret B six equidistant holes are drilled and a steel bush E inserted; the locating pin F is kept in position by the spring G. The lever I, pivoted at J, passes through the piece H, which is fastened to the lower end of the locking pin, F. The flow of the cutting compound is automatically controlled by the position of the turret, the liquid flowing only when operating tool is in position. The fluid enters the base of turret by means of the pipe K and flows through to the passage N, thence to the tubes O, which pass along a groove in the shank to the outer end of the various tools. To avoid any undue leakage, the leather washer Q is placed in a recess and bears upon the lower surface of the revolving turret B.

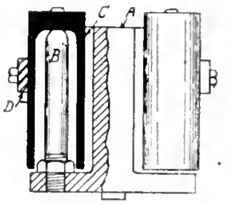

FIG. 4. JIG FOR HOLDING SHELLS ON PLANER

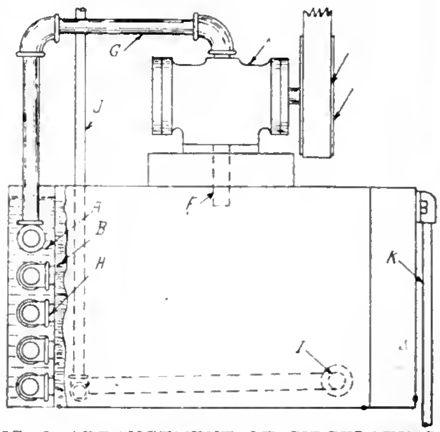

FIG. 6. ARRANGEMENT OF CIRCULATING PUMP AND COILS IN QUENCHING TANK

Self-tightening Chuck

Fig. 8A shows a special self-tightening chuck used extensively in this shop. Body A is screwed on to the lathe spindle; collet B, which has three equidistant slots milled in the nose, is checked into piece A as shown. A tapered sleeve C formed of three pieces of hardened tool steel grips the body of the shell when chuck sleeve D is screwed upon body A. Any slippage of the shell in the chuck now causes collets B and C and sleeve D to turn, thus causing the tapered nose of sleeve D to tighten on

C and increase the gripping force accordingly.

Groove and Base Finishing

When the inside of the shells are finished, they are taken to two Rahn-Larmon 20-inch engine lathes, where the copper band groove is cut, sides undercut, small groove for cartridge case is put in, base diameter finished below copper band groove, base faced and corner rounded. This operation is shown in Fig. 9; the turning and facing operations are performed by the tools held in the special four-sided turret tool box shown at the front of the saddle, while the undercutting of the groove faces are made by the device secured at the back end of the cross-slide. The ball-bearing hollow centre shown in the tail-stock spindle supports the end of the shell while the groove is being turned. These special tools, as well as the expanding mandrel, were all designed and built by the superintendent and shell shop forman.

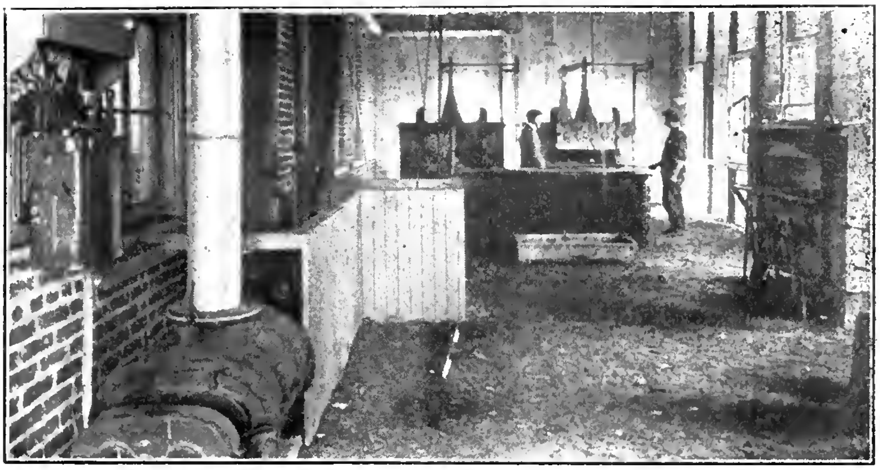

FIG. 5. VIEW OF HARDENING ROOM. HEATING FURNACES IN BACKGROUND

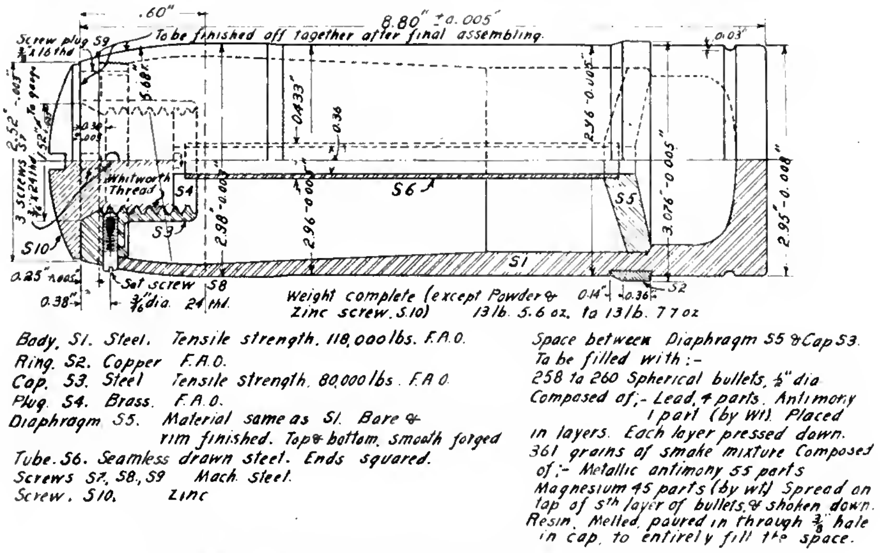

RUSSIAN 15-PDR. SHRAPNEL SHELL WITHOUT FUSE NOSE.

Undercutting Device

The device for undercutting the sides of groove is shown in sketch, Fig. 10. This is built of a flat plate provided with two grooves machined at the proper angle in which slide tool carriers A and B. These carriers have a number of rack teeth cut to engage with pinion C which when oscillated by the lever D brings either tool into operation as desired. Adjusting stops are provided at the outer end of each tool carrier as shown, and also a positioning stop for the shell.

Tool carriers A and B are a good close sliding fit in their respective grooves, and are retained in position by suitable keeper plates fastened to the main casting.

Knurling for Copper Band

It was originally intended to knurl the copper band groove at the same setting as that for turning, but owing to the great pressure required it was thought advisable to reverse the shell, thereby bringing the copper band groove closer to the head-stock bearing. The base of the shell is held in a special chuck and the open end run in a special centre in the tail-stock spindle.

During this setting the outside diameter, from the rifling groove to the open end, is finished turned to two diameters, the main portion of the shell being 2.96 inches diameter, while a short section back of the nose contour is left 2.98 inches; two Mueller 16-inch engine lathes are used for this operation.

Cold Nosing

The ninth operation, that of cold nosing, is performed on a Brown-Boggs No. 320A geared straight-sided press. As previously stated, it was thought that the open end of the shell would require heating to close the nose to the desired shape, but as the wall of the Russian shrapnel, at the open end, is lighter than that of the British shrapnel, and also requires less reduction in diameter, several shells were nosed cold and thoroughly tested; the result showing that the cold nosing, while being equally satisfactory in quality, is also much more economical.

Finishing the Nose

The nose being formed, the shells are taken to one 18-inch and one 20-inch Greaves-Klusman engine lathes and one Rahn-Larmon 18-inch engine lathe; these lathes are fitted with the special turret as shown in Fig. 8. The sequence of operations on the nose are: finish outside contour, cut thread, form inside contour and face end to length. A point bearing on a cam at the rear of the saddle guides

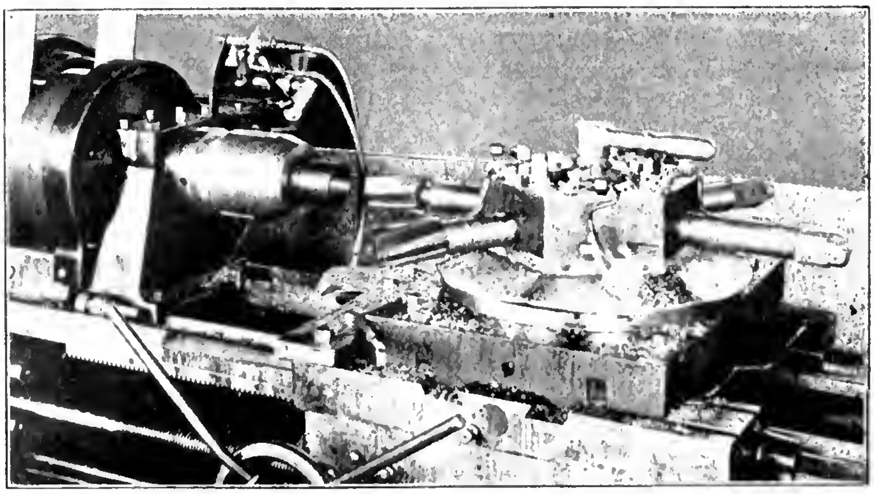

FIG. 7. SPECIAL TURRET FITTED TO ENGINE LATHE

the movement of the cross-slide while the contour of the nose is being formed.

Outside Grinding

At present the outside diameter is being finished by filing, but two Ford-Smith grinders are being installed to take care of this operation. The power required to run these grinders will be supplied from a single Crocker-Wheeler motor of suitable power.

Copper Banding

The shells are now ready to have the copper band put on. This operation is performed on a Canadian Fairbanks-Morse banding press.

The shells are held in a special chuck on a Greaves-Klusman 18-inch engine lathe while the copper band is turned, the base being supported in a special

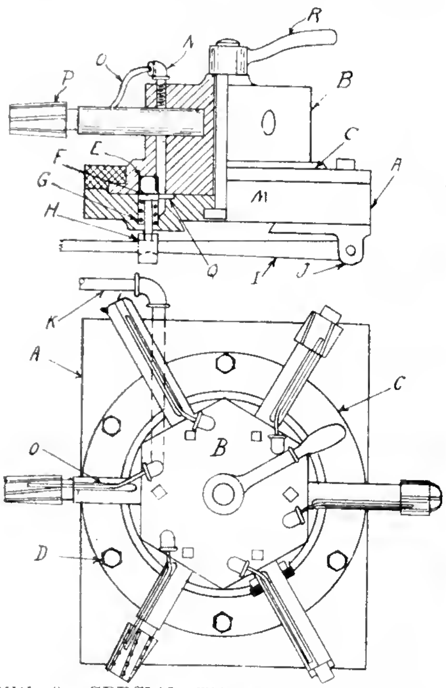

FIG. 8. SPECIAL TURRET FOR USE ON REGULAR ENGINE LATHES

ball-bearing cup centre. This operation is shown in Fig. 11. The special chuck is secured to the lathe spindle, and to insure added rigidity is run in the steady-head shown; this steady rest has a bearing of babbitt metal. The shell is held by closing the split chuck by means of the two-piece clamp.

Painting

The shells are now taken to a paint spraying arrangement where the inside receives two coats. The diaphragms are also thoroughly coated by dipping in a bath of paint.

Assembling

The steel tube and diaphragm are then placed in position and taken to the tables shown in Fig. 12, where the charge of powder, bullets, resin, etc., is put in. The process of charging these shells differs considerably from that of the British shrapnel. When the tube and diaphragm

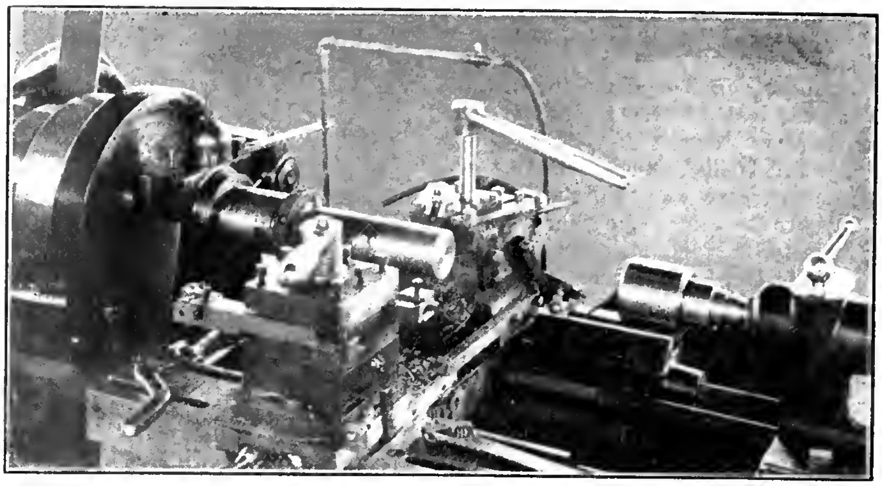

FIG. 9. CUTTING GROOVE AND FINISHING BASE ON SPECIALLY EQUIPPED ENGINE LATHE

are in position a charge of 90 bullets with a small quantity of smoke powder —13 drs. 5 grs. of 55 per cent. magnesium and 45 per cent. antimony—is placed in and pressed firmly down by means of the 20-ton Weaver screw press, shown to the right of Fig. 13; after this first charge of 90 bullets has been pressed in, a second lot of 50 bullets are poured in and pressed firmly down; a third lot of 50 is put in and pressed and a fourth lot of 50 similarly treated. This makes a total charge of 240 bullets.

To bring the shell up to the required weight it is necessary to add from 6 to 9 loose bullets as the specifications call for a charge of 240 bullets with a supply of 310 grains of smoke powder. A small quantity of heavy No. 1 petrolatum is used on top to hold the shot in position.

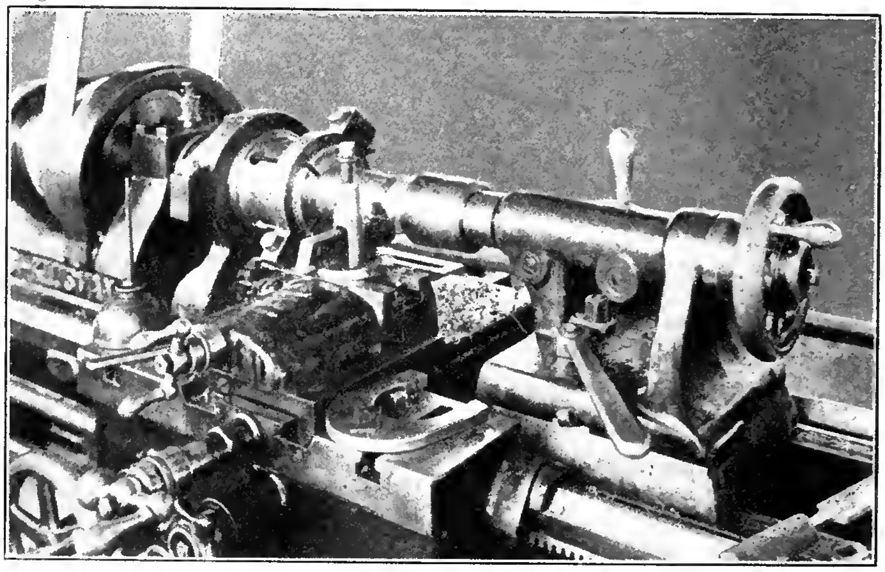

FIG. 11. TURNING COPPER BAND

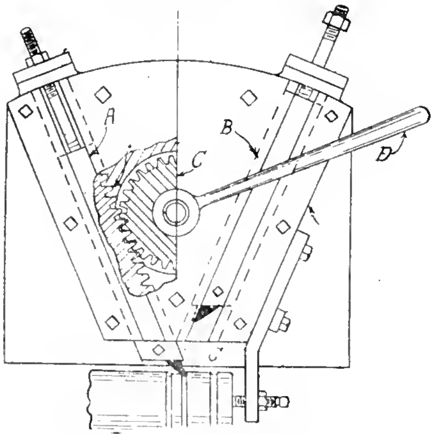

FIG. 10. UNDERCUTTING FIXTURE

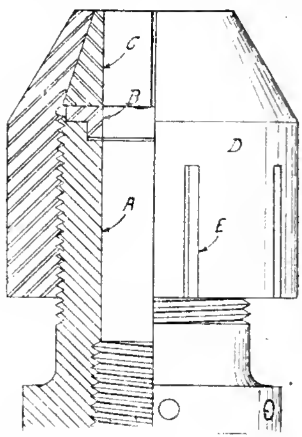

FIG. 8A. SELF-TIGHTENING CHUCK

FIG. 12 CHARGING DEPARTMENT SHOWING BULLET HOPPER, POWDER TANK, LOADING PRESS AND RESIN FURNACE

Fixing Cap and Tube

When the correct weight at this point has been obtained, the steel cap is screwed firmly into the nose of the shell. In place of securing the top of the powder tube to the cap by solder (as is done in the British shell) a small brass plug is screwed firmly down upon the upper end of the tube.

Through the cap or socket are two tapped holes: a smaller air vent hole, and one a little larger, through which the melted resin is poured into the shot chamber; these holes are then plugged.

Shot Filling Arrangement

The arrangement of these various operations can be clearly seen in Fig. 12. The shot tank shown to the extreme left is filled with bullets, and the spout is so designed that a chamber at the mouth is enclosed by two slides. This chamber will contain an average of 90 bullets at each charge. The large elevated tank shown in the centre contains another supply of bullets; the S-shaped pipe to the left ends in the filling arrangement which is shown in detail in Fig. 13. This device is so designed that 50 bullets are transferred from the feed pipe to the shell at each movement of the lever.

In the position shown, the bullets fall down through the pipe I into the piece F, which contains, when full, 50 bullets; the lever G is then swung over until the piece F is over the hole J in the lower plate B, when the bullets fall into the shell K placed below. The plate C, which is secured to the piece F, moves with it and closes the opening from the pipe I until the lever G is brought back to the previous position. The Weaver screw-press is seen in the foreground, and the resin tank is shown to the extreme right.

Powder Hopper

Midway between the two bullet tanks is the galvanized iron receptacle which contains the smoke powder that is placed in the shell with the first charge of 90 bullets. The small funnel-shaped measuring device is shown resting on the edge of the box. A sketch of this powder box and measure is shown in Fig. 14. The hopper is filled at B and the powder passes down into the box A where it is dipped out by the small measure F. The gauge or scraper E, secured to the cover C, is used for removing the surplus powder from the top of the funnel F, which when filled level with the large end contains the exact quantity of the smoke powder.

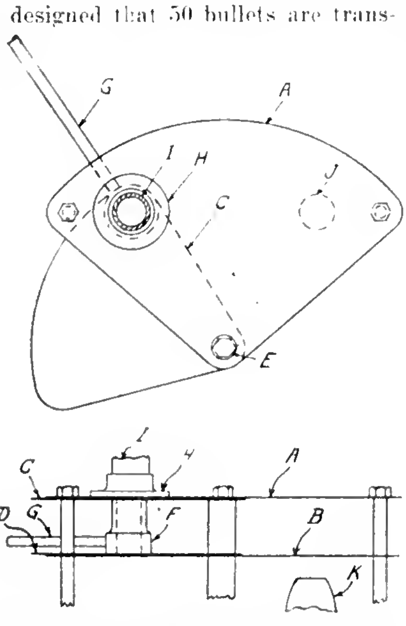

FIG. 13. BULLET MEASURING DEVICE

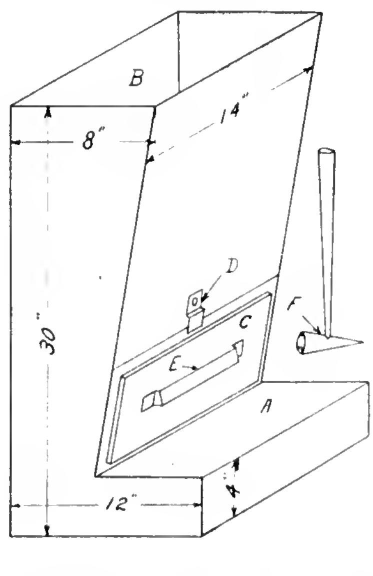

FIG. 14. POWDER TANK WITH MEASURE

Finishing Nose

When the shells have been filled and the cap and plug screwed in, three holes are drilled through the nose. These are tapped for 3-16-inch headless set-screws. Two of these are to secure the cap or socket, while the third is drilled and tapped through shell nose and cap to hold the time fuse in position.

The extending parts of the screws are then filed off and the nose of the shell and cap finished by polishing. The shells are then lacquered by applying lacquer with a brush while the shell is revolving between centres on a lathe.

ALL modern explosives, no matter what their base, depend upon nitric acid or nitrates. Common black powder contains saltpetre, which is nitrate of potash. Smokeless powders are nitro-cellulose. The higher explosives are trinitroglycerine, trinitrotoluene, trinitrophenol, etc.

In normal times these are made from the actual nitrates, most of which comes from Chile. But the Chilean deposits have not sufficed to supply the enormous demand made by agriculture and the arts in recent years, and now that thousands of tons are needed for explosives, the demand has multiplied many times over.

Therefore, it has been necessary to draw nitrogen from the air, where it exists in inexhaustible quantities. Nitrogen at a high temperature combines with many other elements. This was discovered only a few years ago, but already more than $100,000,000 is invested in factories where the process is used for making nitric acids. The chief of these are in Norway, Sweden, Switzerland and Germany, in each of which countries there is an abundance of water power.

There are several processes, the earliest of which was invented by Birkeland and Eyd. It consists of making the nitrogen and the oxygen of the air combine by using the electric arc. This is the process used at Notodden, Norway, where 280,000 tons a year are produced.

By this process the gases have to be cooled to a very low temperature to prevent the bioxide of nitrogen from decomposition.

CALIFORNIA has the longest electrical transmission line in this country, a current of 150,000 volts being transmitted a distance of 240 miles, from Big Creek to Los Angeles.

Sheet Metal Elbows: Their Development and Laying Off-III

By J. W. Ross

In order to thoroughly understand the principles involved in the development of cylindrical and other forms, such as are met in sheet metal work, a considerable knowledge of geometry is desirable. Through the medium of these articles, the author places practical examples at the disposal of our readers, and the knowledge to be gained by a close and persistent study of the principles and methods employed will well repay the time spent.

ELBOW OF CLINKER COURSES

IN Fig. 14 is shown the elevation view of a five-coursed 120-degree elbow of ½-in. plate. This system of fitting the courses is generally termed "telescopic" plating; it should be more correctly called "clinker" plating.

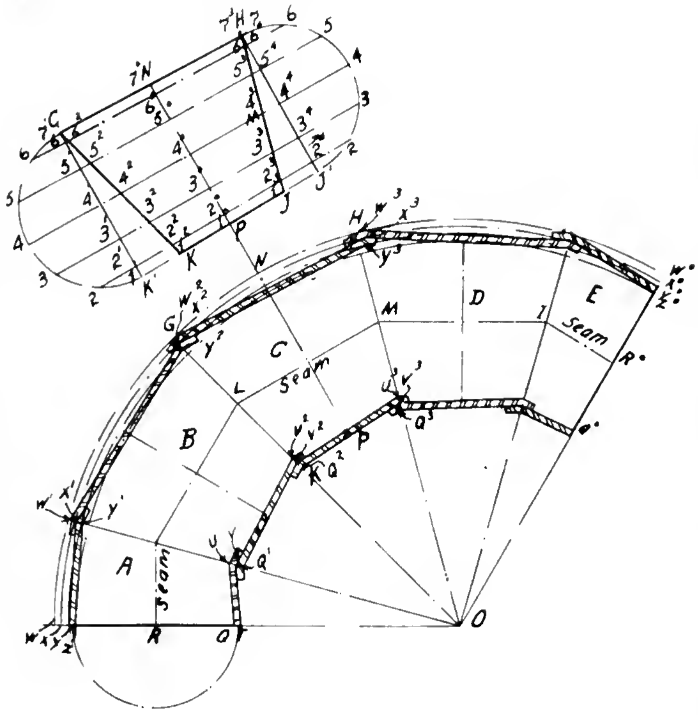
It will be observed that the end of one course fits over, whilst its other end fits in; thus each course will be conical in form.

Many platers prefer to lay this out by triangulation, which is generally too slow for most problems. Again, some prefer approximate methods which certainly give a quick layout, but much time is wasted and the work generally poor, when the courses are being fitted and lined up for riveting, very often the holes being unfair and completely "blind."

The method given below of developing this type of elbow is much superior and quicker in every way than that of triangulation or approximate methods. Triangulation will be dealt with in a forthcoming isue. The student may then use the method suitable to his own ideas. It was stated that each course was conical; therefore, it will be developed on the principle as described for cones—that is, by radial lines. The method of constructing the elevation view is different to the preceding problems.

Measure off OR, Fig. 14, equal to 36 inches, and RQ, RZ each equal to 9 inches; thus the inside diameter of the elbow will be 18 inches at ZQ, Fig. 14. With O as centre and OR as radius, strike the arc RR^0. Construct the angle ROR^0 equal to 120 degrees. Mark off YZ, YX and XW each equal to the thickness of the plate. With each of these points as radii to the centre O, strike in the arcs ZZ^0, YY^0, XX^0, and WW^0. The mitre lines are obtained as previously explained.

Each of the end courses equals one, and each of the intermediate courses equals two. According to the drawing, the courses A and E equal two, while BCD equals 6, making the sum of 8. Now, 8 divided into 120 degrees equals 15 degrees. By dividing the arc WW^0 into 8 equal parts and connecting these points by straight lines to O, the mitre lines are located. Draw RS at right angles to ZRQ. With the dividers set to the distance OS, mark off the points OL, OM, and OI on the mitre lines. Connect these points by straight lines, as S to L, L to M, M to I and I to R^0; these lines will be tangent to the arc RR^0.



FIGS. 14 AND 15.

To show a cross section of the plate thickness, connect Z to Y^1 and Y to X^1. Y^1 and X^1 are of course the intersections of the mitre line. So with the arcs YY^0 and XX_0. Similarly connect X^1 to Y^2 and W^1 to X^2; also proceed with the remaining lines that are drawn in, as shown on the arc ZZ^0, YY^0, XX^0, WW^0, Fig. 14.

The throat thicknesses are next drawn in. Mark off QT equal to the plate thickness. With dividers on S and distance SY^1 measure off SU^1, also SV^1 and SQ^1 equal respectively to SX^1 and SW^1. Connect Q to U^1 and T to V^1. In the same manner, with L as centre, the distances LY^2, LX^2, and LW^2 are transferred to LU^2, LV^2 and LQ^2 respectively. Connect V^1 to U^2 and Q^1 to V^2. Similarly proceed with the remainder of the construction.

By this method of construction, if the end courses EA were joined together they would conform to the courses B, C, or D. So if one of the intermediate courses is marked off, the end courses may be marked from the pattern.

The course C will, therefore, be developed; and to save confusion of the lines on this drawing the neutral lines of course C will be transferred over to Fig. 15. The heavy lines GHJK, Fig. 15, represent the neutral lines of course C, Fig. 14, or, which is equally the same, of the courses B and D. Parallel to the centre girth line PN draw from G the line GK^1, also from H the line HJ^1. Extend the line KPJ to the points K^1 on GK and J^1 on J^1H. Now, as will be seen, K^1GHJ^1 forms an ordinary frustum of a cone, so accordingly will it be developed. Bisect GK^1 at 4^1. With 4^1 as centre and 4^17—which is of course, the neutral radius—as radius strike the half-end view 147. Divide this into a number of equal parts and number accordingly. Project these points to intersect GK^1 at right angle. Bisect HJ^1 as at 4^4. With 4^4 as centre and radius 4^47, strike the half-plan view 147. Divide this into the same number of equal spaces, as in the view through GK^1.

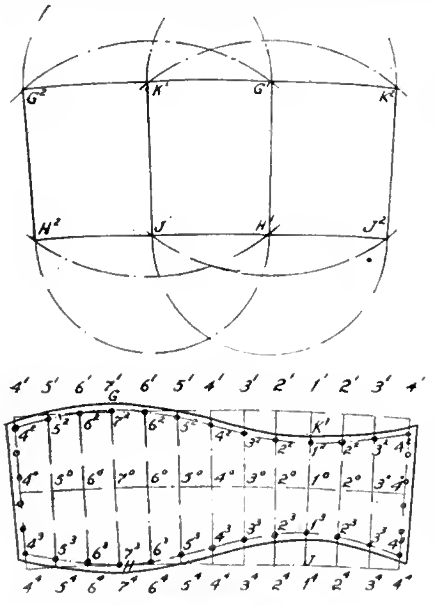
Number these points in the same consecutive order, and project lines from them to intersect HJ^1 at right angles. Connect points on GK^1 with corresponding points on HJ^1. The lines connecting these points will not be parallel, but will be radial, because HJ^1 is shorter than CK^1: GK^1, J^1K being part of a cone. Where these lines intersect the inclined lines GK and HJ, number as in Fig. 15.

For explanatory reasons only, the outline K^1GHJ^1 is transferred over to Fig. 16, as $J^1K^1G^1H^1$. With trammels or dividers on H^1 as centre and H^1K^1 as radius, strike the arc K^1K^2. With J^1 as centre and radius J^1G^1, strike the arc G^1G^2. With K^1 as centre, K^1G^1 as radius, strike the intersecting arc G^1G^2. Similarly with the same radius and G^1 as centre, strike the arc K^1K^2. Again, with K^1H^1 as radius, G^1 and K^1 as centres, strike the respective arcs J^1J^2 and H^1H^2. With J^1H^1 as radius and centres J^1 and

H^1, strike the intersecting arcs H^1H^2 and J^1J^2.

Draw an even curve through the points $G^2K^1G^1K^2$, Fig. 16, by the aid of a light wooden batten placed on the four points. In a similar manner draw in the curve through the points $H^2J^1H^1J^2$.

Again, for the benefit of instruction and to avoid a confusion of lines, Fig. 16 has been transferred over to Fig. 17, as shown by $4^14^14^1$ for the upper curve and 4^44^41 for the lower curve. Measure off from and on each side of 4^1—of the centre line 4^14^4—along the curve 4^14^1 a distance equal to half the neutral stretchout of the diameter 1^17^1, Fig. 15, which equals half of $22 \times 3.14 = 34\frac{1}{2}$ inches. The total of the stretchout for $4^14^14^1$ will be 69 inches. Similarly the stretchout for the lower curve will be $56\frac{1}{2}$ inches; therefore, half of this stretchout measured along each half of the curve from the central point 4^4 will locate the whole stretchout as enclosed



FIGS. 16 AND 17

by the points $4^14^14^44^4$. Divide 4^1 and 4^4 each into 12 equal spaces—that is, six spaces at each side of centre 4^1 and centre of 4^4, which is the number of spaces each half plan view is divided into in Fig. 15. These points on Fig. 17 are connected by straight lines and numbered accordingly. The curved centre line 4^0, 4^0, 4^0 is drawn equidistant to the curves $4^14^14^1$ and $4^44^44^4$.

As PN, Fig. 15, is equidistant from the inclined lines GK and HJ, therefore the distances 1^01^2, 2^02^2, etc., are equal respectively to 1^01^2, 2^02^2, etc. As both sides of the centre line PN are alike it will only be necessary to take one set of measurements to be transferred over to Fig. 17. These distances be measured from and at each side of the centre camber line $4^04^04^0$, Fig. 17.

Set the dividers to distance 1^01^2, Fig. 15; transfer this over to 1^01^2 and 1^01^3, Fig. 17. Proceed similarly by transferring over from Fig. 15 the distances 2^02^2, 3^03^3, etc., to Fig. 17, as 2^02^2, $2\,2^3$, 3^03^2, 3^03^3, etc. An even curve drawn through these points locates the rivet line and these points also indicate the rivet centres if desired. Divide the seam rivet lines 4^24^3, 4^24^3, each into the same number of rivet spaces. Twice the diameter of the rivet hole, measured from the rivet line, will give a suitable lap. For caulking purposes in water or steam-tight work, one and a half times the diameter of the hole will be more suitable for laps, the rivet holes, of course, being spaced according to the class of work.

Fig. 17 shows the complete pattern for courses B C and D. If the plate be cut on the line $4^04^04^0$, Fig. 17, the upper part would be the pattern for course E and the lower for course A.

MONTREAL HARBOR CONSTRUCTION WORK

AN inspection tour on October 18, by the three commissioners, Major David Seath, secretary; F. W. Cowie, chief engineer; M. P. Fennell, jr., and J. Vaughan, superintendent of railway terminals, revealed the fact that by the middle of next summer the permanent construction work of Montreal Harbor will be finished for that section of the port which stretches from McGill Street to the hay shed.

For some years the harbor work has been impeded to some extent by the very effort of the harbor authorities to bring the port up to an efficiency which would enable it to deal with the business which the West sends down to it. From next summer the problems of this part of the harbor will concern solely the administration of the facilities provided.

The commissioners on leaving their office proceeded to the place where the large addition to Elevator No. 1 is being constructed by the Fuller Construction Co. They expressed pleasure at the progress which had been made. The lower set of bins are now completed to the top, and the set on the shore side, which are about 19 feet higher, will be completed shortly. The whole thing will be covered in before the cold weather arrives, so that all through the winter work can go ahead with the installation of machinery and necessary interior work. The cupola will be on in a few weeks, and the commissioners were able to say after the inspection that the new building would be ready by the early summer of 1916.

Victoria Pier End

The commissioners also inspected the office building in its new position on the wharf, where it was moved to make room for the addition to Elevator No. 1. In the basement of this building the police department will be housed, as last year.

The last crib just put in place at the river end of Victoria pier has completed that pier, so far as its length is concerned. All that now remains to do is to build it up to the high level. Although this will not be accomplished this season, the work will be sufficiently advanced so that the winter ice will not damage it. Next year it will be finished in good time, and, when it is completed, Victoria pier will add about 2,500 lineal feet of harbor frontage to that available for ocean vessels, and 4,800 lineal feet along the inner side for lake and river vessels.

The commissioners and the departmental heads accompanying them afterwards proceeded by flat car along the higher level tracks of the harbor system down to the dry dock, to see what progress had been made with the filled-in land, and the extensions being made by the Canadian Vickers Co. The work done here has been little short of extraordinary, the activity being indicated by the fact that parts filled in only last summer are already built upon.

The party also traversed the high level tracks of the system, which have now been extended beyond Dominion Park, to connect ultimately with the Pointe aux Trembles wharf, built opposite the Canada Cement Co. premises. The flat car took the party almost down to Pointe aux Trembles, a sufficient indication of the progress of this extension of their railway system.

"Emden" Bombardment Effects.—An instance of the damage done to the German cruiser Emden by the Sydney's shots, states the Ironmonger, is to be found in one of the mementoes recently taken from the vessel. It is an oblong piece of metal, fairly smooth on one side, but on the other side presenting an appearance similar to that of a piece of jagged rock. It consists of a portion of the fireproof safe of the Emden and some silver dollars from a drawer of the safe. The explosion must have blown the dollars into the steel, and the heat of the flames which burst from the vessel shortly after the explosion melted the whole into a conglomerate mass of silver and steel. This gives a very clear indication of the conditions in those parts of the ship where the bombardment was most felt. It does not seem likely that much will be saved from those parts except for the melting pot or the foundry.

IT HAS been estimated that nearly fifty per cent. of the potential water power of this continent is available in the States of the Pacific Coast, or nearly twelve million horse-power.

CONTEMPORARY WAR ARTICLES

Embracing Information and Data Drawn from a Variety of Sources Relative to and Arising from the Prosecution of this Many-Sided European War

THE WORLD'S GREATEST ARSENAL

THE vast contracts received by various corporations in Canada and the United States have impressed most people by reason of the number of workers required to complete them, as much as by the value of the amounts involved. The fact that these contracts have been distributed over wide areas, has so detracted from their direct appeal to the general public, that an account of conditions pertaining in a restricted area like the valley of the River Clyde in Scotland is of absorbing interest to those of us engaged in munitions manufacture. The Glasgow Herald publishes the following particulars of wartime activity:

It must have been borne in upon every Clyde workman that the vast steel and shipbuilding area which exists between Motherwell and Dumbarton is one of the most extensive and important in the eyes of the nation. The Clyde area has become, indeed, the largest centre in the world for the production of war materials. This compliment is paid, notwithstanding the great developments which have taken place on the Tyne, at Barrow-in-Furness, Sheffield, Woolwich, etc. In the number of industries and the comprehensive scope of their productivity the Clyde has become the world's greatest arsenal. With the development of aircraft, too, the tendency must still be in favor of concentration on the Clyde and adjacent areas. The South of England is much too exposed to the menace of aircraft. Woolwich Arsenal and the Portsmouth and Devonport shipbuilding yards may be said to have seen their day. Once peace is concluded there will be an exodus for the north, where already some striking developments have begun in this direction, of which it is impossible here to speak. The Clyde is certain still more to outdistance all rivals in its importance as a naval and military centre of production.

Over 150,000 War Workers

It may surprise Clydesiders to discover the extraordinary number of men who are engaged locally in the shipbuilding and allied industries. At last census (1911) almost one-quarter of the males resident in Lanarkshire were engaged in such kindred trades. Lanarkshire's industries monopolized the labor of 212,482 males. Miners occupied premier place with 56,209 men employed, while the steel trade had 20,168 workers, and the engineering shops required the services of 20,145, and shipbuilding 14,528—a gross total of 54,841 in the steel and shipbuilding trades alone. This excludes Dumbartonshire, Renfrewshire, and North Ayrshire, all of which impinge on the Clyde munition area. Since the war began new munition factories have been laid down in many districts within the area, enormous developments have taken place in shipyards, gunshops, etc. Adding the men within the Dumbartonshire and Renfrewshire sections, plus the men engaged in the new workshops and factories, there cannot be less than 100,000 workers engaged in the Clyde area today on Government work, while the number of females may be set down at 5,000.

The Wages Bill—£600,000 a Week

Taking the men's wages at £3—an average balance between the smaller earnings of the unskilled laborer and the fat earnings of the skilled worker, swollen by abnormal overtime—this gives an influx into the Clyde area of £300,000 weekly in wages for the men, and, at £1 10s per head, the females take £7,500. In many cases unprecedented wage bills have been earned. Young, energetic fellows, having their time-sheets marked double time for Sunday labor, etc., have been known to earn £7 10s in a single week, while many steadily earn from £5 to £6. It is stated that one Clydebank family of five or six sons, plus the father—all skilled workmen—is earning £40 weekly—which is at the rate of £2,000 a year.

The total sum distributed by the Government in prosecuting the war is £4,500,000 daily, or £31,500,000 a week. It is well-known that in warships and war material the wage bill represents about one-half of the total cost (on battleships the wage bill is actually 60 per cent. of the total). On this basis, Clyde industries are receiving a total of over £600,000 weekly. In other words, almost one-fiftieth of the money expended by the nations on the war is finding its way into Clyde channels. This is proof, again, of the enormous importance of the West of Scotland to the nation—and the Allies—in the prosecution of this gigantic struggle.

A Shipbuilding Record

Leading up to this present-day abnormal development, the Clyde had already been for a number of years the largest and most comprehensive war arsenal in the world. For a long period it had been the largest warship-building centre extant. On the Admiralty List were five yards capable of producing battleships, while no other centre possessed more than two. For a number of years prior to the war the Scottish river had constantly on hand, in varying stages of construction, as many as four battleships of the Dreadnought type, representing, with a host of auxiliary craft, as much as £17,000,000 of taxpayers' cash. When Mr. Churchill visited the district several years ago he declared there were as many ships then building on the Clyde as represented the total fleet of a second-rate naval power. Since the Dreadnought era began the Clyde has completed the following battleships and battle cruisers—a list which roughly constitutes one-fourth of the total number of capital ships under the command of Admiral Jellicoe—the Colossus and Ajax at Greenock; Conqueror and Benbow at Dalmuir; Inflexible, Australia, and Tiger at Clydebank; and the Indomitable and New Zealand at Fairfield. There are certain other ships, about whose construction nothing may be said, however.

A Self-Contained Area

But it is in the multiplicity of its establishments that the Clyde leads the world. A battleship may be produced and equipped in every detail, everything being manufactured locally. There are immense gun shops, gun mounting departments, armor-plate shops, shell factories ad lib., a torpedo factory, and torpedo-testing range. The explosive works in our midst are the largest in the world. Then there is the highly technical establishment which produces range finders for guns. Every Navy extant has received some of Glasgow's products in this department—the British of course securing the specialties exclusively. Not even organized Germany can show a single centre with such multiplicity of warlike productivity.

The honor of leading the Clyde in this gigantic development of becoming the greatest naval and military arsenal in the world belongs to the firm of Wm. Beardmore & Co. It is very well known that the Parkhead establishment produces all kinds of weapons up to the largest naval guns in use on his Majesty's ships. Included amongst these are weapons for sisters of the Queen Elizabeth, completing "somewhere" in this country. The firm began its gun department ten years ago, on the personal initiative of its present head, Sir Wm. Beardmore, whose enterprise in this and other directions has proved a lucky asset for the nation to-day. Prior to the guns the Parkhead works had acquired great repu-

tation for their armor-plate. This involves the most complex metallurgical problem undertaken by steel manufacturers; and here, be it said, the product of Messrs. Beardmore stands unrivalled throughout the world. It is not generally known that until recently nearly all the English firms which produced armor-plate did so on a process invented and patented by Krupps, of Essen, to whom a royalty of 10s per ton was paid for license to work it. Messrs Beardmore never used this process. They adhered to their own methods, and by costly experimentation evolved a plate which is superior to the Krupp.

Universal Providers

During the Russo-Japanese war it was an odd coincidence that vessels engaged on both sides had materials in their hulls or engines which had come from Parkhead. The Russian battleship Petropavlovsk, which was sunk by a mine outside Port Arthur, had materials—engine, shafting, etc.—which were manufactured at Parkhead; while the Japanese battleship, to name one only, the Shikishia, had plates which were produced in Glasgow.

Messrs. John Brown & Co., Clydebank, come next to Messrs. Beardmore in the importance of their products for war. They built the Japanese battleship Asahi, which formed part of the squadron under Admiral Togo in the Sea of Tsushima when the Russian fleet was completely annihilated. Several years ago when on a visit to Glasgow, the Japanese naval commander paid a special tribute to the fine work of the Asahi in the greatest naval battle since Trafalgar. Messrs. Brown & Co., have at present the superintendence in Russia of one of the Government yards, where our Ally's new fleet is being prepared. One of their great successes has been achieved in turbine engine construction, developing the American Curtis system, and they have been favored with many Admiralty vessels designed for fast steaming. The Tiger battle-cruiser, the fastest in the world, came from this yard soon after war broke out.

In order to compete successfully with the great armaments firms of Vickers & Company at Barrow, and Wm. Beardmore on the Clyde, Messrs. John Brown & Co., combined with the Fairfield Company and the Coventry Ordnance Company, laid down a splendid factory at Scotstoun some years ago for the purpose of completing gun mountings. Messrs. Beardmore's is the only establishment on the Clyde which can completely build and equip a warship, while Messrs. John Brown & Co., and the Fairfield yard come next—a considerable distance behind, it must be admitted—in the multiplicity of their products and capacity to build and equip a battleship.

"BARGING ABOUT THE NORTH SEA"

WHEN Rear-Admiral Sir David Beatty, on a recent occasion spoke of the British Navy as "barging about the North Sea" (says the "Scotsman"), all who heard him realized the measure of the Navy's regret that there had been so much difference between what it wished to do and what it had been given an opportunity of doing. To sweep the seas of the world clean of the surface craft of the enemy within a few months, to impose upon his commerce a strangle hold, to fight land batteries and cover the operations of troops on distant coasts, to smash a way up tropical rivers, and edge over the shoals of a flat coast-line with great guns working mightily for the sake of a stricken people—these have been great achievements, but they have not satisfied the fleet. "The sure shield of Britain" has not failed her, and the utmost ingenuity of an absolutely unscrupulous enemy has been countered successfully and in silence. The whole world was made aware of the awful things which the German submarines would achieve, and now the whole world is aware that they have achieved practically nothing, and is almost imploring Britain to tell what she did to them. Such is the difference in method. The resounding phrases of the commission to the submarines of the enemy to "cleanse the North Sea" produced no evidence of disturbance over here. His underwater craft put out with injunctions of frightfulness showering upon them, and with impressed neutrals awaiting results, but they were just quietly gathered in, and the manner of their ending was a mystery to the Fatherland.

Opportunity Lacking

There has been lacking, however, the one great opportunity, as compared with which all the achievements indicated are regarded by the British Navy as of little moment. The enemy's fleet has remained locked away behind the minefields, and there has been no smashing contest such as would recall the famous days when the navies of nations fought. Deprived of the great test—the test which it believes would be final—the British Navy is disposed to look upon all else that it has done as mere "barging about."

It has been seen that "barging about" has included the reduction practically to impotence of the submarine service which the enemy had regarded as his most valuable sea weapon. It has included much more than that. If it were possible, indeed, to tell at this time all that "barging about" has meant, the gratitude and pride with which the nation—and not alone this nation—regards the Silent Service would be deeper than ever. The earliest days of the war were stirring days at sea. They seem far off now, and the lessons they provided have been well learned. Our Fleet at that time had yet to measure the infamy of the enemy, and to realize that to the German nothing was sacred but his success. There were some fine feats of seamanship during the first black, wild winter round coasts darkened and disguised, and amid courses mazed and mixed and falsified in "the blindfold game of war." Be it remembered that many of the ships of the Navy had been drawn across the world to the work on the lightless, shallow, narrow sea, where the enemy was assured that his mosquito craft from the harbors behind Heligoland would hunt at will. Sailormen will appreciate the seamanship which kept the ships in safety at their work, day and night, on such coasts, under such conditions. Efficiency and accuracy in the engine-room; efficiency, accuracy, and our heritage of "sea sense" on the bridge; these were the factors which, in darkness and storm, upset all the calculations of the enemy, and nullified all his efforts. The nerve of the Fleet was better, and the Fleet itself stronger, at the end of the winter than it had been at the beginning. The German calculation was that its nerve should have been gone, and the best of its ships destroyed. The strain only proved the quality of the Navy.

A "Tramp" Incident

There were many comparatively unimportant incidents of almost a year ago which at the time sent a grin round the fleet and did their part in the general hardening. These were connected, for the most part, with the attempts of the enemy to maintain supplies for his submarines. Many of our tars will recall one such incident which involved quite a feat of seamanship. It occurred out on the North Sea, and possibly a little west of the Long Forties. Just about twelve months have gone since the affair, but it still raises a smile in certain quarters. A fast, light cruiser of our Navy on a very dull morning, after a calm, cold night, sighted a cargo vessel under a neutral flag, and came to regard her with some suspicion. The "tramp" was kept under observation for a long time before she received any evidence at all of being watched. To outside appearance, the neutral was in that condition which brings to his mouth the heart of a skipper expectant of salvage, and no doubt more than one trawler that morning had glanced at her hopefully, and again and again, for a signal that she had broken down and wanted a tow.

Lying off in the distance, the warship was satisfied that the tramp was not "going lame," but was waiting for something. Having arrived at that conclusion, the neutral was approached in

the usual way, and an examination was made. In the making of the examination the "gullible and unsuspecting" Britisher rather scored. The officer entrusted with that duty did not spend much time over it. That was not necessary. He was apparently satisfied as to the bona fides of the tramp when he shouted a cheery "Good-bye," and returned to his ship. His report was to the point. Whilst "looking at nothing" he had seen enough to be certain that the vessel was neither a neutral nor an innocent tramp steamer with a defect in the engine-room. The warship disappeared, and the tramp "limped" along, with no more than steerage-way on, as before. Throughout eleven weary hours patient eyes and ready guns were turned on that unsuspecting merchantman, and at length darkness fell. Then there was vouchsafed the watchers that for which they had waited so long—the combination of lights on the neutral. It was a clever combination, in which her ordinary lights played the part of permanent basis. Having learned all that she seemed likely to learn by waiting, and being now certain that anything that was about to happen to the cargo steamer would not be seen by any submarines that might be about, the warship made a move in the darkness. During the whole eleven hours the position of the suspect had hardly changed. The extra lights of the combination suddenly vanished on the tramp as the cruiser bore nearer, and that was the first indication to the invisible fighting ship that the crew of the tramp had heard the rumble of machinery somewhere and were taking precautions. Then an astounding thing happened. On the quarter of the tramp a section of the darkness materialized in the most startling fashion, and from it there poured over the merchant ship a crowd of sturdy fellows who dashed for the bridge and dived for the engine room and had the ship in their hands and her crew prisoners within five minutes. The cruiser, slipping up in the blackness had laid her long, slim bows alongside as sweetly as ever she laid them along a jetty, and the boarding party asembled forward did the rest. The crew of the tramp had no time to do anything in the way of warning anyone. It was smart work, and a valuable capture. Stores of food, drums of oil fuel, and spare torpedoes were carried under the sham cargo of the supply ship. She was steamed into port by her prize crew, and she steamed very well indeed. It is said that she steamed out of port again not long after, and that on resuming her interrupted duties with a new crew she exercised a distinctly demoralizing influence upon certain units of the submarine service of the enemy.

Beatty's "Boarding"

The feat at seamanship involved in laying the cruiser alongside her quarry so suddenly and so closely in the darkness was noteworthy, but on the occasion of the fight at racing speed between our battle cruisers and those of the enemy, off the Dogger Bank, last January, there was provided a no less notable example of the splendid skill with which the fighting ships are controlled. It will be remembered that when the Lion dropped out of action, Admiral Beatty transferred his flag to the Princess Royal. The Princess Royal, steaming at full power, was using her guns with effect upon the fleeing enemy, without intermission. To recall her from that work in order that the Admiral might get on board was apparently not thought of. She had to be overtaken, not recalled. To catch her the Admiral boarded the Attack. The destroyer was asked to overtake a battle cruiser which was running at well over 30 miles per hour and to put the Admiral on board without delay. The Attack was "opened out" to the task, and it may be questioned if even her designers dreamt of the speed she developed. The Princess Royal was overhauled, but kept on her furious way, her guns crashing out unceasingly. Steadily the Attack worked closer, and very soon, with engine-room responding with marvellous precision to the demands of the bridge, she was reduced in speed to enable her absolutely to cling to the speeding leviathan ahead of her, and with both vessels rushing along at that terrific pace the Admiral passed from the destroyer to the battle cruiser and resumed his place in the action.

GUNMETAL: ITS COMPOSITION AND APPLICATIONS

THE following is a short summary of an article recently published in the "Foundry Trades' Journal":

The compositions which come under the heading of gunmetal include chiefly the following:

Copper	Tin	Zinc
88	11	2
88	11	1
87	8	5
87.5	6.25	6.25
84	12	4

The first of these is the recognized Admiralty steam metal, the second is used for general admiralty work, the third is for propellers, the fourth for bolts, and the fifth is a well-known metal for bearings. In making gun-metal, the copper should be melted first at a fairly rapid rate in a good fire, a cover of broken glass or powdered charcoal being used to protect from the atmosphere or from furnace fumes. When the metal is molten, the tin should be added, and finally, just prior to pouring, the zinc, the temperature then being raised slightly to overcome the chilling effects of the addition. A small piece of phosphor-copper used as a deoxidiser adds fluidity and aids soundness. The great essential in Admiralty specifications is purity of raw materials; the copper used should not contain more than 0.25 per cent. of arsenic, nor the zinc more than 0.25 per cent. of lead. Care must be taken not to overheat the metal in the furnace, nor to keep it at full heat for any longer time than is necessary: the molds must be ready when the metal is ready. The maximum temperature of pouring may be taken as 1,300 deg. Cent., and the aim should be to bring out the metal at this heat in order that it may enter the mold at not less that 1,100 deg. Cent. The rate of pouring should be more rapid than with iron; in fact, the metal should be poured as rapidly and fully as possible. Gun-metal being a somewhat sluggish metal, it is well to flush the mold by pouring extra metal through to clears away any gases which are liable to be entrapped.

The molds may be either green-sand or dry-sand. Much small work can be cast in green-sand, but if difficulty is experienced with blow-holes, it is advisable to dry the molds, and this is frequently done in larger work, as the trouble may be due to gases created in the molding blowing through the metal to escape. These gases are, of course, practically removed during the drying process, and there is only the contained air in the mold to be attended to. An open-grained sand usually obviates this trouble. Holes due to the liberation of dissolved gases are only dealt with by more careful melting or by changing the copper for a purer brand. In order to allow rapid pouring, the gates should be ample. Parts to be machined should be cast down; as any oxide present works to the top. The sand used in moulding should be of open texture and drier than is used for iron. The molds should be well rammed and well vented.

TO MAKE a permanent cement used for stopping leaks in steam pipes, where caulking or plugging is impossible, mix black oxide of manganese and raw linseed oil, using enough oil with the manganese to bring it to a thick paste; apply to the pipe or joint at leak. It is best to remove pressure from the pipe and keep it sufficiently warm to absorb the oil from the manganese. In twenty-four hours the cement will be as hard as the iron pipe.—Locomotive Engineering.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

TRANSFER TRUCKS

IN order to meet the demand for a thoroughly efficient transfer truck of low cost, the George P. Clark Co., Windsor Locks, Conn., have placed on the market the two models illustrated.

FIG 1. TYPE WN30 TRUCK FRAME DEPRESSED

Type WN30 shown in Figs. 1 and 2 is adapted for loads from 500 to 1,000 lbs. The frame is made of channel steel, is designed to raise 1⅞ in., and is fitted with

FIG 3. TYPE YN10 TRUCK FRAME DEPRESSED

three wheels 6 in. diameter by 2 in. face having roller bearings and steel axles.

Fig. 1 shows the truck with the top frame in its lowest position with the lifting link resting on the front rod ready to elevate the frame. When the handle is pulled forward the top frame is swung upwards on the supporting links to its maximum elevation, when the lifting link can be unhooked from the rod by pressure of the operator's foot on the front end of the link which projects forward of the handle.

The platform which straddles the frame in the usual manner may now be transported to its destination and lowered by reversing the operations. This type is made in two sizes each having a capacity of 1,000 lbs., and taking a maximum size platform of 32 x 32 inches, and 42 x 32 inches respectively. These trucks weigh 130 lbs. and 140 lbs., the minimum height from floor to top of frame being 6 inches in both sizes.

A heavier type of truck for maximum loads of 2,200 lbs. is shown in Figs. 3 and 4. These are of substantial construction being built of malleable iron and steel, and of such proportions as will insure rigidity in use. The axles are of steel, the iron wheels 6 in. x 2 in. with dust proof roller bearings, and hardened and ground rolls and sleeves.

The elevating gear consists of combination cam-gears, the necessary movement being obtained by means of an anti-friction rack connected to the neap swivel and operated by the handle of the truck. The rack in the neap swivel moves only when the handle is swung away from the anti-friction roll, consequently the neap swivel can be turned completely around, which is of advantage when it is desired to move the truck with frame depressed.

The combination cam-gears provide a rolling lift which reduces lifting stress to a minimum. When elevated, the upper frame is positively locked in position by the sliding bolts, either of which is sufficient to hold the load elevated, while they cannot be disengaged except by raising the handle and again lowering it. All work of elevating or moving the truck is performed by the handle which is rigidly pivoted to the neap swivel.

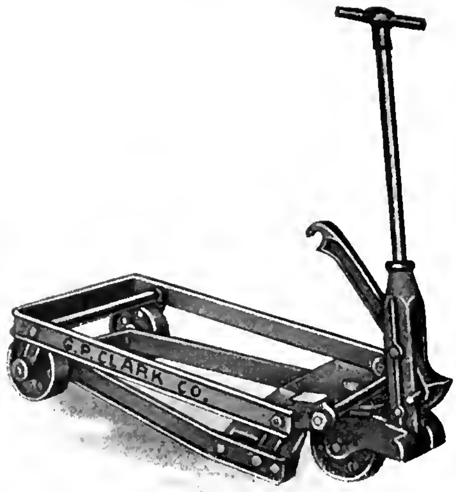


FIG. 2. FRAME ELEVATED

This truck type YN10 is built in four sizes, all having a minimum height of 6 inches with a lift of 2 inches. The maximum platform sizes vary from 32 x 32 inches to 52 x 38 inches, and the weights from 225 to 275 lbs. respectively.

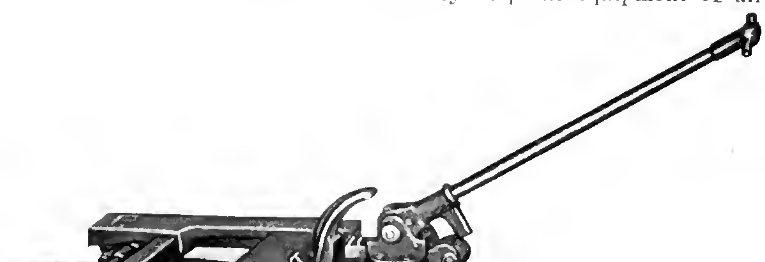

FIG. 4. FRAME ELEVATED

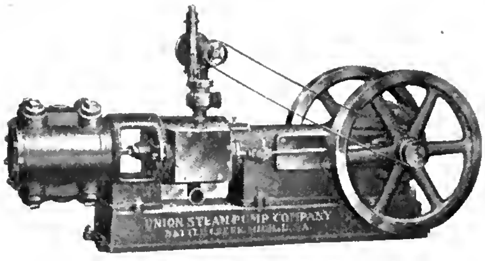
ENCLOSED AIR COMPRESSORS

THE constant demand for increased efficiency in plant equipment of all kinds has been met with corresponding effort on the part of builders. Air compressors are one line of manufacture which has been the object of consistent effort.

Creek, Mich., build a full line of compressors which embody all that is desirable in modern air compressor design. These machines are of both vertical and horizontal types, and are adaptable to

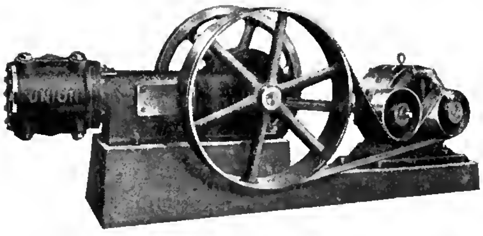


STEAM DRIVEN FLYWHEEL COMPRESSOR

all drives. They are built with open frames as well as enclosed, and also duplex single-stage, and two-stage.

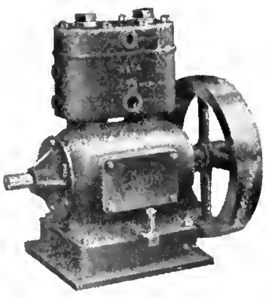
Enclosed construction, as shown in the illustrations, completely protects all running parts from grit or dirt, and enables the splash system of lubrication to be adopted. Access to the various parts is obtained through suitably placed cover plates.

Air valve design has received all the attention which this important feature



COMPRESSOR WITH MOTOR BELT DRIVE

deserves, and the flat steel-disc valve as developed by the makers is the result of many years' experience. This valve has a very small lift accompanied by freedom from noise, and its period of service is



VERTICAL DUPLEX COMPRESSOR

indefinitely lengthened by the use of special heat-treated steel in its construction.

In addition to the types illustrated, there is also manufactured a line of single cylinder vertical compressors from 3 x 3 inch to 6 x 6 inch, all of the water cool type.

SHRAPNEL SAND BLASTING MACHINE

SAND blasting shrapnel shells so as to thoroughly clean them externally and internally has found considerable favor. The apparatus here illustrated and described is a product of the W. W. Sly Mfg. Co., Cleveland, Ohio. The table of this machine has six shell pockets. Three of these are in the blasting department, and the other three as shown in the illustration are in the open. Thus, while three of the shells are being cleaned, the operator can remove the other three that have been cleaned, replacing them with three more to be blasted. Constant operation is thereby attainable.

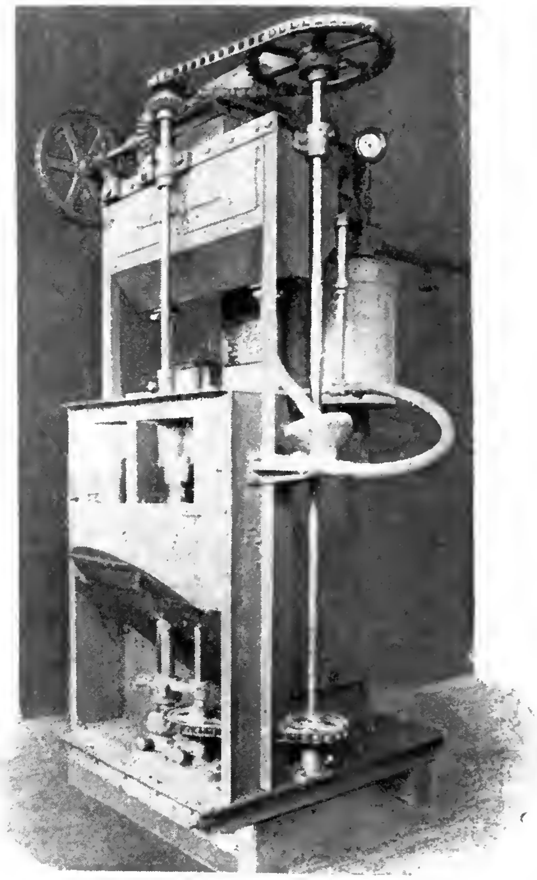
The apparatus when connected to an exhaust system is claimed to be nearly dustless and absolutely automatic in operation. All sand used falls into an elevator boot and is elevated by means of buckets into a storage hopper, from whence it is returned by gravity to the three nozzles shown. The sand is in this way used over and over again, until it becomes so fine that it is practically useless for its purpose.

All parts of the machine which are subject to wear are enclosed with sheet iron, and not exposed to the sand blast. On the sand blasting table proper it will be noted that the division plates are lined with wood to protect the steel plate. The wood is inexpensive and easily replaced. The only parts which are subject to wear are the nozzles, which may be replaced at a slight expense.

Each nozzle is provided with an air nozzle which is not subject to wear, and has a constant opening so that the air consumption does not increase during operation. The standard air nozzle has a 1/4 in. opening, which can be increased or decreased to suit conditions and the amount of air available.

The machine is designed so that the copper band groove and the upper part of the exterior of the shell are blasted by separate nozzles. When necessary to blast a small portion of the interior of the shell, the apparatus can be arranged to do so. Its capacity for continuous running is from 150 to 200 shells per hour.

The speed of working and the peculiarly clean surface obtained by means of sand blasting, combined with the absence of danger, due to scalding when using wash tanks, etc., commend this machine to all shell manufacturers who aim at producing the best quality of work with the least possible amount of rejections.



SHRAPNEL SAND BLASTING MACHINE.

DURANT COUNTING MACHINES

AS the result of a regrettable error, the description appearing October 21st of the new model counting machine made by the Durant Manufacturing Company, of Milwaukee, Wis., was accompanied by an illustration of an entirely different article. The discrepancy, while sufficiently obvious to our readers, is

MODEL "D" DURANT COUNTER

inexcusable, and in reproducing the correct illustration of the Durant Model "D" Counter, we tender our apologies to both the Durant Company and the makers of the article, which was inadvertently illustrated.

SHELL COMMITTEE RECONSTITUTION

SHELL manufacture in Canada having passed beyond the "immediate emergency" stage, it naturally followed, if the efforts of our metal-working plants continued to be requisitioned, that something more akin to a commercial basis for the distribution of future contracts would be developed and established. Recent happenings indicate progress in such a direction.

We are not of those who seem to see an investigation of the Shell Committee work looming up, and much less still would we expect to find, as a result, a series of unsavoury revelations. The organization of a Shell Committee for Canada was beset with difficulties relative to its personnel that many of its detractors neither appreciate nor want to.

The emergency of the situation a year ago made it altogether impossible for either official British expert knowledge or that of her Allies to be available. Assistance from the United States could not be considered on account of that country's neutrality. We were therefore put upon our own resources, if we would undertake the work. It was also fully realized that we were placed in the gracious position of aiding materially in our Empire struggle, and incidentally of helping ourselves.

The personnel of the Shell Committee had of necessity to consist of both a civil and a military element, and as regards the former—the most severely criticized, it would have been utter folly to have attempted to exclude such of our prominent manufacturers or their representatives who found a seat in its councils.

The Shell Committee appreciating the responsibility laid upon them, took no chances, of course, in placing contracts. Shell orders, even small as they were at first, did not come to us simply to give opportunity to experiment. Shell shipments were urgently required and shipping dates might be stated to have been the very essence of every contract.

Like every other big issue to be met—the "Message to Garcia," or "Shells to Britain," the men on whom the onus was laid took it as a personal matter, and staked their manufacturing reputations on the enterprise. They let contracts at the start-off to just such firms as their personal knowledge and experience warranted. It is therefore assuming nothing, much less making endeavor to mitigate what spiteful criticism dubs an indiscretion, when we say that manufacturers' representatives on the Shell Committee, were in every sense justified in sharing the bulk of the initial contracts among the firms in which they were interested.

Regarding prices paid for shells in Canada, much ill-advised criticism is being directed against the Shell Committee. A substantial price was in the earlier stages paid for the work; this has not, however, been maintained. It was but reasonable that a good margin should be provided our machine shops, not only to allow them to install the necessary equipment, but to make haste slowly towards success.

D. A. Thomas has been here to find out just what stage of productivity we have reached; to find out if we have taken advantage of the good margin price to install and equip, or to find out if we have simply temporized. He has got all data of that nature together, and the No. 1 firms—large and small are going to participate soon in the distribution of larger than ever shell orders and larger than ever shells. The best answer to all requests for a commission of investigation and the best opiate for the friction gossip is that D. A. Thomas has seen to the former and is satisfied, and that the latter in consequence does not exist.

The Shell Committee is being reconstituted, because Britain is now in a position to spare men with expert knowledge to co-operate with us in the work. Further, some of our manufacturing representatives are only too glad to again get opportunity to give their whole attention to the particular enterprises with which they are connected. The association of Brig.-Gen. Bertram and Lt.-Col. D. Carnegie, at least, with Lionel Hichen and R. H. Brand as the administrative board of the new Shell Committee, will express publicly Mr. Thomas' appreciation of the sincerity of purpose with which the civil section of the old committee carried out its work, and at the same time commend the high-degree achievement which it realized.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, Que., Nov. 1, 1915—Conditions generally in the steel and metal markets show some improvement over last week. Quotations on many products have been advanced and are very firm. The shell industry continues to develop and the heavy demand for steel for munitions is keeping the mills operating at capacity. Indications point to a considerable increase in tonnage.

Preliminary investigations are being made with a view to establishing an ordnance factory at some central point. Sir Frederick Donaldson and General Mahon have been visiting several mills and shops with the object of ascertaining if these plants can be utilized for making parts of guns. A large number of tenders have been received for the new eighty-million dollar shell order, and contracts will likely be distributed during the present week. With the reorganization of the Shell Committee, the production of shells will be stimulated.

Steel Market

The steel industry is still taxed to the utmost trying to meet the continued demand for bars and billets. Orders for 6-in., 8-in. and 9.2-inch shells are expected to be placed this week and this will call for production of a larger tonnage of billets for the forging of these shells. Some progress has already been made by a few of the larger plants on the forgings for these shells, and it is expected that little delay will be experienced in making the necessary preparation for the machining operations.

Machine Tools and Supplies

Little change is noted in the machine tool situation. The delay in delivery is one of the chief drawbacks to the shell makers. Delivery at a specified date is very uncertain, and with the increased demand for tools, caused by the placing of new orders for shells, is expected to complicate rather than relieve the situation.

The prospect of a demand for heavy tools, suitable for the manufacture of heavy projectiles of the 6-in., 8-in. and 9.2-inch type, will open a new field for the tool builder.

Sheets

The present indications show a tendency to higher quotations on dull and bright sheets, which may go into effect at any time. Demand for black sheets for early delivery has increased somewhat and the demand for galvanized sheets has also improved. Large enquiries are being made for blue annealed sheets. An advance in sheets is expected shortly.

Metals

Quotations on the various metals show little change over that of a week ago, with the exception of tin and lead, both of which have advanced. Rumors of a heavy demand for copper from Europe for war purposes is causing producers to anticipate an advance in price. Quotations are unchanged this week.

The increase in tin appears to be caused by the apparent scarcity of this metal, which is, by general indications, somewhat exaggerated. Little improvement is noted in the consumption and no change in the visible supply.

Spelter at present is steady, but may advance before the close of the week.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

Lead has shown a small increase within the last few days, but the general market is little changed from a week ago.

Old Materials

The prices on scrap metals are holding firm; slight advances are noted, with prospects of further increases shortly.

Toronto, Ont., Nov. 2.—The industrial situation continues to improve, and the marked increase in production is shown by the development in the export trade. Exports already far exceed in value the imports for corresponding periods, and there is every indication that this tendency will continue for several months. As a result of the war, Canadian manufacturers are producing many articles which were previously imported. This should prove a permanent benefit to the country and increase the number of industries in Canada. In addition, outputs have considerably increased in products which have been manufactured in Canada for some years, thus assisting materially in consolidating the position of the industries affected. The value of orders for articles purely for war purposes has already reached a large total and will increase considerably. The Dominion Customs revenues for the month of October increased by two and one-half million dollars over the corresponding month last year, and in the seven months of the fiscal year the increase was nearly fifty-three million dollars.

The reorganization of the Shell Committee is proceeding quietly, and will probably be completed very shortly. The prospective development in the shell industry and extension of the powers of the committee render this step desirable. The committee in future will to all intents and purposes be directly responsible to the British Minister of Munitions. Tenders for 6 in., 8 in., and 9.2 in. high explosive howitzer shells have been submitted by several firms, and contracts will be awarded at an early date. The possibility of establishing an ordnance industry in Canada is under consideration. Experts are engaged in obtaining the necessary data as to the firms which might be able to manufacture parts of guns to be assembled later in a large central plant under Government supervision.

Steel Market

Extraordinary activity prevails in the steel market and the demand for steel for munitions continues to increase. The production of steel rounds has reached a heavy tonnage and mills have all the business they can handle. The Algoma Steel Co. is the latest concern to take up this class of work, they having secured an order through J. P. Morgan & Co. for 30,000 tons of rounds, while other contracts involving 20,000 tons of rounds have been closed. The contracts for the larger calibre shells, which will be placed shortly, will call for a considerable increased production of steel.

Conditions in the galvanized sheet trade are still somewhat unsettled. Owing to the increase in the price of black sheets and the possibility of higher prices for spelter, galvanized sheets have an upward tendency, although there is no change in prices to be noted this week. Black sheets are strong, No. 28 gauge being firmly held at $2.10 Pittsburg basis for early delivery, and mills are refusing to sell for extended shipments.

The steel trade in the States is in a very satisfactory condition. There is no abatement in the demand for various lines of steel, which is in excess of the producing capacity of the mills. Makers are still unable to meet the heavy demand for large rounds for shells, and the mill capacity is sold up months ahead. In addition to steel rounds, there is a good export demand for barb wire, forging billets, blooms and wire rods. The continued heavy demand for billets is forcing prices upward. Bessemers billets are now quoted at $25, open-

hearth billets $26, and forging billets $40 base f.o.b. Pittsburg.

Pig Iron

The situation in the pig iron trade is improving, and prices are holding firm. The consumption of low phosphorous iron is increasing, and there is also a better demand for foundry iron.

Old Material

The market is quiet, but prices are firm. There is not much demand for old metals except heavy melting steel, which is strong. Prices on scrap copper are unchanged, and there is a fair demand.

Machine Tools

Great interest is being manifested in the machine tool trade over the contract for the larger calibre shells, which will be awarded shortly. These shells are 6 in., 8 in. and 9.2 in., and weigh 180, 250 and 290 lbs. filled, respectively. Heavier tools will, therefore, be required than are being used for the 18-pdr. Lathes with 24 in. and 30 in. swing will be in good demand, although considerable difficulty may be experienced in getting delivery this year on new equipment. Quicker delivery is obtainable on second-hand lathes, and the market for this class of equipment will be stimulated. It is reported that some contracts for the large shells have already been placed, but no official statement has been issued as yet.

Supplies

Business continues active in machine shop supplies, and prices are very firm. The lines in greatest demand consist of chucks, taps and dies, drills, belting and belt fasteners, cutting compounds, etc. Prices of high-speed twist drills are still withdrawn, and quotations are subject to immediate acceptance. The high-speed tool steel situation is unchanged, stocks are very low and prices continue to advance. A sharp advance of 10c is to be noted in turpentine, due, it is said, to a shortage of supplies at Savannah. Turpentine is being quoted in Toronto at 80c per Imperial gallon. Prices of solders have advanced ½c, due to the strength in the tin market. Quotations on benzine have been adjusted; the new price is 21½c per gallon in barrels.

Metals

The market is holding steady, and, with the exception of an advance in tin, there are no price changes to note. The copper market is still very quiet, and the buying movement has not started, although it is anticipated that there will be one shortly. Spelter is higher in London, but unchanged locally. Lead is stronger, and will possibly advance. The antimony situation is unchanged, and prices are holding firm. There is a continued scarcity of aluminum, and supplies of this metal are almost unobtainable. The situation in the metal market locally is unchanged, and trade reports show business as being brisk in metals for munitions.

Tin.—A more active demand for spot and near-by tin has had a favorable effect on the market. There is, however, no improvement in actual consumption and so change in the visible supply. It is doubtful, therefore, if the advance is justified by conditions. Tin has advanced 2c, and is now quoted at 39c per pound.

Copper.—There is no change in the situation; the market is quiet, and there is little business doing. It is reported that producers are in control of the market—which indicates a possibility of higher prices. Local quotations are firm and unchanged at 19½c per pound.

Spelter.—The London market has advanced, but it has not affected New York except to make that market firmer. The market is uncertain, and consumers are inclined to defer buying, except those making munitions, until the situation clears up. There is every possibility that the demand for spelter for galvanizing will increase, as the substitutes which have been tried have not proved a success, and there is also a possibility of the demand for sheets increasing. Local prices of spelter are unchanged and firm at 17½c per pound.

Lead.—The "Trust" have advanced the price of lead $3 per ton to a basis of $4.90 New York. Local prices, however, are unchanged meanwhile. There is a continued big demand for lead, and the position is a strong one. Local quotations are very firm at 6¼c per pound.

Antimony.—There is no improvement to be recorded in the market for antimony, which is under the control, for all practical purposes, of the British Government. There is a tremendous demand for this metal, and English makers have practically ceased to export any except to the Dominions, and then only for munitions. Quotations are firm and unchanged at 35c per pound.

Aluminum.—The market is very firm, and has an upward tendency. There is a big demand for aluminum, but it is very scarce and difficult to obtain. Local quotations are entirely nominal at 60c per pound.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Messrs. S. Ruperti and Alexsieff, care Military Attache, Russian Embassy, Washington, D.C.

CANADIAN TRADE RETURNS

THE total Canadian trade for the six months of the fiscal year ending September 30 last was well over half a billion dollars, according to the official statement issued by the Hon. J. D. Reid, Minister of Customs. The figures show a very satisfactory advance over the corresponding six months of 1914, which were $500,634,000, as against $559,529,000 for the six months just ended, or in round figures a total increase of trade of 59 millions of dollars.

The trade for September just ended was as follows: Merchandise entered for consumption, $38,026,000; domestic exports, $46,129,000, or a total of $84,156,000. This is a considerable advance on September, 1914, when the imports were $36,567,000, and the domestic exports $31,796,000, or a total of $68,364,000.

The export of manufactured goods for September was very heavy—reaching a total of $9,244,000, compared with $5,188,000 for September, 1914. Of agricultural products, $11,139,000 worth were exported last September, as against $7,478,000 for the corresponding month last year. The export of domestic animals and their produce was also heavy—being $10,188,000, against $7,063,000 for September, 1914.

It is interesting to note there is a substantial increase in the export of domestic fisheries for the month of September, the total being $2,750,000, against $1,900,000 for September, 1914.

The importation of free goods for September last was $15,746,000, compared with $13,991,000 for September, 1914. For the six months ending September last Canada imported of free and dutiable goods, $213,588,000. During the same period she exported $246,392,000, so that our value of exports were considerably greater than our imports.

On the whole, the showing is a very satisfactory one, the duty collected for the six months just ended being $44,418,000, compared with $42,857,000 for the corresponding period of 1914.

WAR BENEFITS CANADIAN TRADE

JUDGING by detailed trade figures published by the Department of Trade and Commerce, the war is having a good, rather than an injurious effect upon Canadian trade. For the six months ending with September of this year, Canada's total trade in merchandise was $486,966,000, or $18,440,000 more than it was for the corresponding six months of last year, for the most part under antebellum conditions. While imports of merchandise during the past six months show a relative decrease of thirty-eight millions, exports of Canadian produce show an increase of sixty-five millions. Exports of foreign products, however, show a decrease of some ten millions.

Figures for the month of September show that even in imports there is now beginning to be an increase, compared with last year, and although the September increase of $1,459,000 may in part be attributed to the unsettled conditions of September last year, immediately following the outbreak of the war, it is believed that it reflects in large measure the definite turning of the tide, pointing to renewed business confidence, replenishment of stocks in Canada, and a steady up-grade tendency in regard to the country's ability to pay for its imports through the increased volume of its exports.

For September, exports totalled $46,129,000, an increase of $14,333,000 over September of last year. Of this increase four millions is credited to manufactures, three millions to animal produce, and five millions to agricultural produce. As for the balance of trade, it is interesting to note that the total exports for the past six months have been $246,000,000, as compared with total imports of $213,000,000.

The value of war orders to Canada in stimulating exports is seen especially in the figures in regard to manufactured exports. For the past six months the total value of manufactured articles exported has been $71,476,000, or $39,559,000 more than for the corresponding months of last year. The increase is more than 100 per cent.

For the full twelve months ending with September last, the aggregate trade in merchandise was $935,254,000, a decrease of $64,809,000 as compared with the preceding twelve months. Imports totalled $417,472,000, a decrease of $114,000,000, while exports of merchandise totalled $474,000,000, an increase of $40,000,000.

DOMINION REVENUE SHOWING INCREASE

THE Dominion revenues for the month of October so far indicate a further substantial increase and the monthly statement is expected to be a most satisfactory one. This evidence and others emphasize the growing strength of the financial position of Canada as a result of the special measures resorted to since the outbreak of the war. There is every probability that the revenue estimate given to Parliament by the Finance Minister in his last budget will be more than realized.

The restoration of a normal situation as regards exchange between the United States and Canada is also affecting beneficially the affairs of the Dominion. The flotation of the $45,000,000 Canadian loan in New York in August and the sale in New York of sterling bills drawn against shipments of Canadian wheat to Great Britain and Europe have brought exchange on New York back practically to par. This is a marked improvement over the situation of three months ago, when the American dollar was worth more than the Canadian dollar, and a premium of one-half to one per cent. in Canadian money had to be paid for funds in New York.

The loan, in addition to stabilizing exchange between Canada and the United States, helped sterling exchange also by providing Canada with funds which otherwise would have been obtained in London. In addition, it conserved the gold reserves of Canada and paved the way for the Anglo-French loan.

It is learned here that the proceeds of the loan were not brought to Canada at once, but were withdrawn gradually so as to gradually reduce the exchange. The Finance Department made over $36,000 in exchange in the transfer of the money.

RECORD OF COPPER PRODUCTION

IT IS announced from New York that the present output of copper by smelters as well as by refiners, is record-breaking, just as it is in steel; but the entire production of copper is not being taken up, as is the case with crude and rolled steel.

During September, it is conservatively estimated that there was a surplus of 30,000,000 pounds in producers' stock in this country. This is based upon an estimated total consumption of 125,000,000 pounds. As the exports were approximately 35,000,000 pounds, this would leave 90,000,000 pounds for domestic consumption. Estimates of melting by domestic consumers range from 80,000,000 to 100,000,000 pounds, but it is doubtful that there is capacity enough to consume 100,000,000 pounds per month, even with the recent extensions made to manufacturing plants.

The total production of blister copper in September is estimated at 165,000,000 pounds, but the refined output is said to have been 5,000,000 to 10,000,000 pounds less; thus it is indicated that there was an increase in smelters stocks of about 10,000,000 pounds, as well as an increase of 30,000,000 pounds in stocks at the refineries.

CANADA'S TRADE WITH GREAT BRITAIN

THE following are the official figures of trade between Great Britain and Canada in the undermentioned articles during September:

	Sept. 1915	Sept. 1914
Exports from Canada.	£	£
Wheat	956,572	2,213,733
Wheatmeal and flour	143,422	87,604
Barley	220,399	46,654
Oats	9,316	115,189
Bacon	250,916	137,955
Hams	21,313	99,815
Cheese	342,055	634,833
Canned salmon	85,069	36,699
Canned lobsters	27,063	43,823
Imports to Canada.		
Spirits	31,023	49,101
Wool	34,086	11,056
Pig iron	17,823	1,945
Wire	544	5,969
Galvanized sheets	6,780	5,898
Tinned plates	2,988	6,344
Steel bars	7,701	7,138
Pig lead	3,266	3,569
Cutlery	9,423	9,300
Hardware	1,790	5,742

PROMISING OPENINGS FOR CANADIAN TRADE

THE Export Association of Canada, acting under the auspices of the Canadian Government and the Canadian Manufacturers' Association, met in London, England, to inaugurate a co-operative movement to extend Canadian trade, especially in countries where German commercial influence has hitherto been predominant.

F. C. Armstrong, joint general manager, presided. The gathering included representatives of the Canadian Car & Foundry Co., the Dominion Bridge Co., the Canadian General Electric , the National Steel Co., the Dunlop Tire Co., the Northern Electric, the Canadian Rubber Co., the Dominion Steel Corporation, the National Steel Car Co., the C. P. R., the G. T. R., and the C. N. R.

The speeches indicated a most promising opening of Canadian trade with Russia, Serbia, Italy, France and other parts of Europe, and also Great Britain. There was a general agreement that Canadian manufacturers and merchants should profit by the example of the Germans, so successfully set before the war, by methods of close co-operation in national interests between producers and railways and steamship companies, to secure the lowest possible freights. An

executive committee was formed to organize a vigorous campaign.

CANADIAN TRADE WITH OUTSIDE COUNTRIES

COMPARATIVE figures of customs revenue contributed by the different provinces are furnished by the annual report of the Customs Department just issued and covering the last fiscal year. Ontario leads with $33,218,000 collected in duties, Quebec comes next with $22,919,000. The revenue from other provinces was as follows: British Columbia, $7,373,000; Manitoba, $6,413,000; Nova Scotia, $2,930,000; New Brunswick, $2,162,000; Alberta, $2,484,000; Saskatchewan, $1,356,000, and Prince Edward Island, $160,225.

Quebec takes first place in exports. In the fiscal year they totalled $181,982,000 compared with $167,685,000 for Ontario. New Brunswick is third on the list with $54,322,000.

Imports from Germany during the fiscal year 1913-14 aggregated $14,500,000. In the year ended March last they fell to $5,000,000. Goods from the United States show an increase, being $428,000,000 compared with $410,000,000 in the previous year. Imports from the United Kingdom declined from $132,000,000 to $90,000,000.

On the other hand, Canada exported to Great Britain $211,000,000 worth of goods and to the United States $215,000,000 worth. There is likewise an increase in exports to France which grew from three million in 1913-14 to fourteen millions in 1914-15.

A small trade was done with Spain. Exports to that country amounted to $489,000 and imports $977,000. Italy took two millions worth of goods from Canada last year and we imported $1,472,000 worth. Two million dollars of exports were sent to Germany in 1914 before war was declared and all trade suspended. To Australia our exports were five and a half millions, to the West Indies nearly six and a half millions and to Newfoundland $4,481,000.

Manufacture of Guns Contemplated—It is believed in Ottawa that the manufacture of heavy guns in Canada is practically assured as the result of the investigation made by Sir Frederick Donaldson and Gen. Mahon, but that the British experts are not disposed to encourage a venture on so large a scale as was contemplated at the conference of manufacturers and bankers in Ottawa a few weeks ago. When Sir Frederick Donaldson and Gen. Mahon have completed their enquiry, it is probable that an ordnance plant will be established on the basis of a stated order from the British Government. The Canadian Government will have the opportunity of taking over the plant at the close of the period if it so desires.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Hedley, B.C.—The Daly Reduction Co. have recently installed a number of new units at their plant.

Hespeler, Ont.—The A. B. Jardine Co. will enlarge their plant. A building 50 ft. x 60 ft. will join the machine shop and foundry.

Valleyfield, Que.—The town will loan the Castings Company of Canada $25,000. This is a new concern, which proposes making shells.

Collingwood, Ont.—There is a possibility of operations being started at the Northern Iron and Steel Works. G. Manton, of Cleveland, Ohio, is an interested party.

Sarnia, Ont.—The Sarnia Metal Products Co. has received from the British Government a war contract, which amounts to a large figure, for shell parts. New machinery to the value of $37,000 has been purchased.

Welland, Ont.—The Electro Steel Metals Co. will extend their plant. The extensions will include a machine shop, 30 ft. x 50 ft., and an office building, 40 ft. x 50 ft., two storeys high. A 6-ton electric furnace will be installed.

Woodstock, Ont.—J. D. Tindall & Son have been given the contract for the construction of an addition to William Baird's machine shop on Dundas street. The addition to be erected will be added to the present building and will be 60 ft. x 90 ft.

Montreal, Que.—The directors of the Laurentide Company have under consideration a large extension to their paper mill at Grand Mere, Que. It was stated that the output of the mill could be doubled by an expenditure of $1,500,000. Mr. Chahoon is president of the company.

Nelson, B.C.—Fred. R. Wolfle, president and general manager of the Florence Mine, states that construction work will start soon on a 200-ton daily capacity concentrator, a hydro-electric power station and compressor plant, together with extensive underground development to cost not less than $150,000.

Electrical

Doon, Ont. — A hydro-electric lighting system will be installed here.

Otterville, Ont.—A hydro-electric by-law will be submitted to the rate-payers on Nov. 5.

London, Ont.—Beattie Bros. are considering the purchase of a number of electric motors.

Owen Sound, Ont.—It is certain now that the power from Eugenia will be turned into Owen Sound by December 1. Construction Engineer A. S. Robertson has arrived here and is busy installing the three transformers, which will carry 1,500 horse-power. The new hydro building is almost completed and the machinery will be installed as rapidly as possible.

Municipal

Renfrew, Ont.—The town council are considering the question of obtaining more power for local industries.

Georgetown, Ont.—It is proposed to loan Henry Corke $6,000 to assist in establishing and operating a woolen mill.

Lindsay, Ont.—The town council has been successful in renting the balance of the Sylvester plant not used for shell-making to the Lindsay Wood-Working Co.

Brantford, Ont.—The city council has purchased from the Waterous Engine Works for $7,100, a combination auto hose and chemical wagon for the fire department.

Port Coquitlam, B.C.—The construction of a waterworks system is contemplated by the City Council at an estimated cost of $35,000. A by-law will be voted on.

Montreal, Que.—The Board of Control are considering the construction of an incinerator, having a capacity of 500 tons per day. The cost is estimated at $200,000.

Hamilton, Ont.—The city council is considering the establishment of a steam power plant, as a reserve, at the pumping station, as an alternative to using hydro-electric power for this purpose.

Sherbrooke, Que.—The council have engaged M. A. Sammett, an electrical engineer, to make a report as to the best means of increasing the power production to meet the demands of local industries.

Penetang, Ont.—A by-law will be voted on by the ratepayers on Nov. 8 to raise $3,500 for water main extensions.

Sarnia, Ont.—Engineer Latour, of Toronto, who is to undertake to get a plentiful supply of pure water for the new Sarnia waterworks, has completed his plans, and will start work at the new plant as soon as the contract with the city is signed. The work will, it is estimated, cost the city about $3,000.

General Industrial

Camrose, Alta.—Work has started on the new Pallesen creamery.

Toronto, Ont.—The Langmuir Mfg. Co., leather goods, will build an addition to their factory.

Southey, Sask.—A big fire occurred at Markinch on Oct. 27, when the Maple Leaf elevator, which contains about 15,000 bushels of wheat, was totally destroyed.

Halifax, N.S.—The paper mill of the MacLeod Pulp & Paper Co., situated at Milton, near Liverpool, N.S., and valued at about $250,000, was totally destroyed by fire last Monday.

Winnipeg, Man.—Owing to the rapidly increasing business, the Robin Hood Milling Co. are planning erecting more mills in the West. George A. Bean, of Minneapolis, is president of the company.

Chatham, Ont.—A deal is on for the sale of the Defiance Ironworks, on Lacroix Street, by the city to a concern in Illinois, and a committee has been appointed to leave immediately for the States to close the deal.

Kincardine, Ont.—The new knitting mill has been completed, and at a special meeting of the town council the agreement between the Circle Bar Knitting Co. and the town was ratified. The latter has made a loan to the company of $15,000, to be paid back in annual installments. Between $30,000 and $40,000 is being invested in the new concern.

Wood-Working

Meaford, Ont.—The W. A. Moore Co. are disposing of their woodworking plant.

The Manufacture of Galvanized Sheets in Canada

Staff Article

Continual evidence of this country's industrial progress is afforded by the frequent establishment of factories for the manufacture of products, the demand for which has hitherto been supplied entirely by foreign producers. The demand for sheet metal in this country assures a market which is distinctly encouraging to the organizers of this enterprise.

A NEW industry for Canada was inaugurated on September 1 last when the Dominion Sheet Metal Co. started operations at their new galvanized sheet plant at Hamilton, Ont. The plant occupies a site covering five acres, and is situated on the belt line railway, jointly operated by the G. T. R., C. P. R. and the T. H. & B. It is within a short distance of Lake Ontario, the water of which being soft and clean, is particularly suitable for the process of galvanizing. If hard water only was obtainable, the effects of lime and other deposits, which prevent the sheets from receiving the coating properly would have to be neutralized.

In normal times approximately 70,000 tons of galvanized sheets are used in Canada per year, and prior to the establishment of this plant no sheets were produced in Canada, the bulk of the supply being imported from the United States and some from England. The product of this plant bears the trade mark of "Premier," but in addition the company makes a "tight-coated" "Premier" galvanized sheet when desired. This latter is especially useful for purposes requiring extreme forming, seaming, etc. The black sheets from which the "Premier" galvanized sheets are made are specified from certain mills, and must conform to exact physical and chemical analysis. All the materials used, such as open-hearth or Bessemer black sheets, spelter, lead, tin, sal-ammoniac and acids, etc., must conform to approved chemical analysis, subject to test.

Plant Layout

The factory comprises two bays, east and west, the former being 50 ft. x 200 ft., and the latter 60 ft. x 200 ft. A spur from the belt line railway runs into the east bay for its entire length; the loading and unloading of the cars is, therefore, done under cover. By this arrangement the handling of the sheets, both black and galvanized, is greatly facilitated. In this bay is installed a 124-in. squaring shear for trimming sheets, which was built by the Bertsch Co., Cambridge City, Ind. Provision has also been made for installing any additional machines that may be required in the future.

In the west bay the entire space, with the exception of a galvanized sheet store room at the north end, is occupied by the galvanizing plant. At the south

A. T. ENLOW,
PRESIDENT AND GENERAL MANAGER.

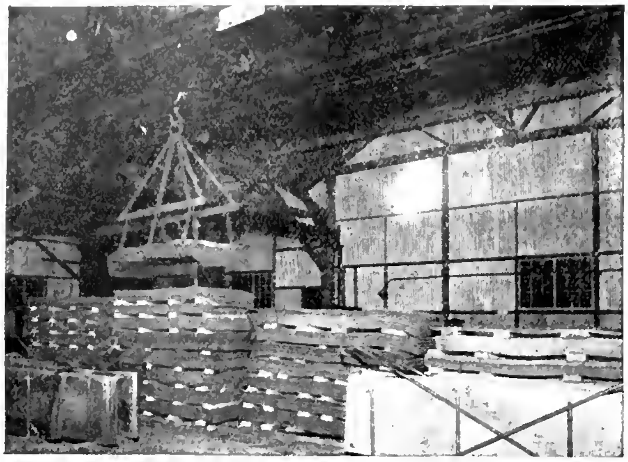
end of this bay is the black sheet storage; further along are the picking machines, washing tanks, storage tanks and galvanizing machines, while extending into the east bay are the cooling machines. The west bay has a monitor roof for providing sufficient ventilation. In handling the sheets, a five-ton electric crane is installed. The crane operates over the entire length of the west bay, and was built by the Northern Crane Works, Walkerville, Ont. When the black sheets arrive on the cars they are placed on hand trucks and weighed, and then moved into the west bay, where they are picked up by the electric crane and transferred to the store room. Here they are placed in piles, according to gauge. When undergoing treatment they are placed side up in crates, to which are attached crane hooks. An interesting feature about these crates is that they are made of "Monel" metal, each crate representing an outlay of $1,000. "Monel" metal possesses the characteristics of being able to withstand the corrosive action of the hot acid in the pickling tank and lasts indefinitely, whereas crates made of bronze would soon corrode. This metal is a by-product, and is obtained from Sudbury, Ont.

Pickling Process

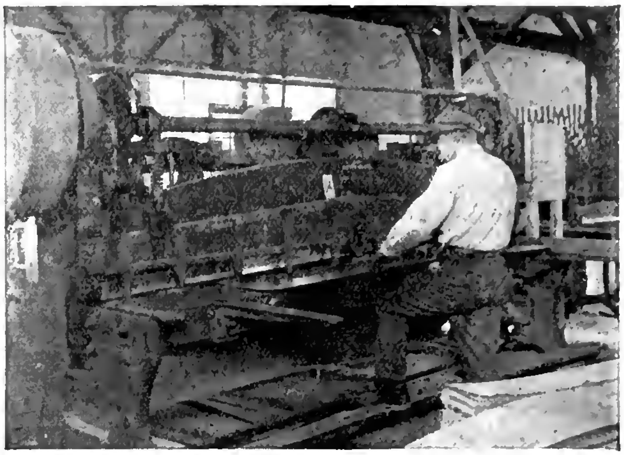
The first process consists of pickling, where the sheets are treated with sulphuric acid to remove the scale and clean the surface, so that when being galvanized the spelter will adhere perfectly to the sheet. The pickling machine consists of two plunger tanks of the latest type, each tank being 12 ft. 6 in. x 3 ft. x 5 ft. deep, and having a capacity of from 100 to 300 sheets, according to gauge, at one operation. The tanks are constructed of solid 8 x 10 in. Georgia pine, and have a bottom of lead. At one side of each tank is a plunger, also made of Georgia pine. The plungers are mechanically operated, and are used to agitate the liquid in the tanks, by which means the sheets are kept separated so that the acid may work more effectually.

There are three pipe connections for each tank for water, sulphuric acid and steam, respectively, the latter accelerating the pickling process. Adjoining the pickling machine are two independent sulphuric acid storage tanks, one for each pickling tank, equipped with floats and gauges for regulating the quantity of acid used. The acid flows by gravity to the pickling tanks. The independent acid tanks are connected to a large acid storage tank located outside the building, and having

NEW PLANT OF DOMINION SHEET METAL CO., LTD., HAMILTON, ONT.



STORE ROOM FOR BLACK SHEETS.



SQUARING SHEETS ON SHEARING MACHINE.

a capacity of 60,000 pounds. The acid is obtained from the Grasselli Chemical Co., which adjoins this plant. The steam for the pickling flush is obtained from a boiler, which will be referred to later in detail. The sheets remain in the pickling liquid for about thirty minutes, after which they are removed to the rinsing tanks.

The machinery for operating the plungers is located in a pit under the shop floor and adjacent to the tanks. The electric motor which drives the machinery is above the floor level, and is controlled by a "Wagner" polyphase motor starter. The motor is 10 h.p., 3-phase, 60-cycle, 220 volts, and was supplied by the Wagner Electric Mfg. Co., through their Toronto office.

A belt drive connects the motor to a pulley on the machine underneath, the power being transmitted to a crank shaft by a link-belt chain. A disc crank at the end of the shaft is connected by means of a connecting rod to another crank, which lifts a vertical rod up and down, thus operating the plungers. The motor starter and acid feed controller are located near together, both being within reach of the operator.

Washing Process

After the sheets have been in the pickling tanks the prescribed length of time, the crate holding them is lifted out by the crane which carries them over to the rinsing tanks near-by. These are two tanks constructed of wood, each being 3 ft. x 12 ft. 6 in. x 5 ft. deep. They contain clean, fresh water, which flows through in a continuous stream, thus effectively washing the sheets and removing all traces of acid. The sheets remain in the rinsing tanks for about thirty minutes.

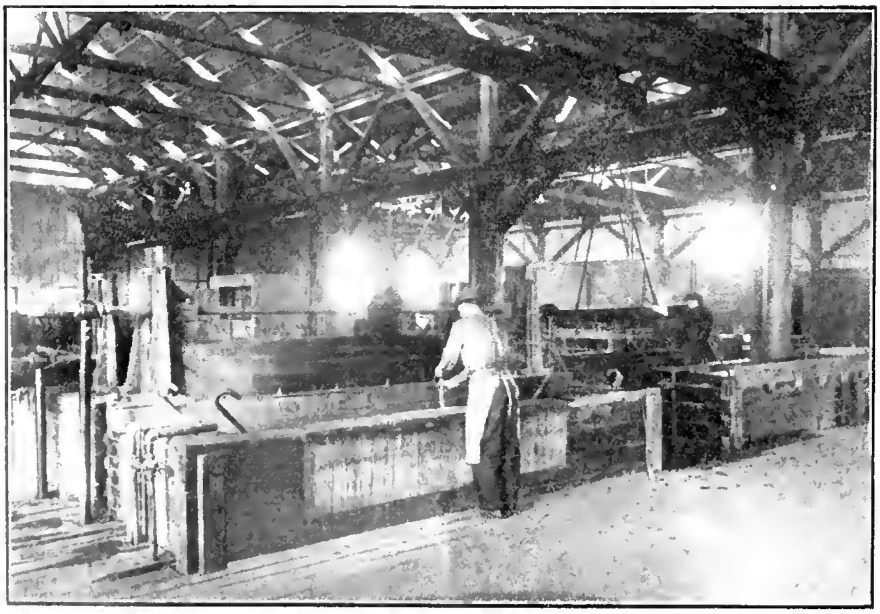
If the sheets are not to be galvanized immediately, they are carried by the electric crane to storage tanks containing water, where they remain until required for further treatment. If required at the galvanizing machine, they are carried to the feed tank direct by the crane, after having first being inspected and placed in skips laid flat. In either case they are carefully inspected before any further treatment.

There are five storage tanks, each being 4 ft. 6 in. x 12 ft. 6 in. x 3 ft. deep. They are also made of wood and contain clean water. After inspection, the sheets are laid flat in a skip, which has a capacity of about 5 tons and placed in the tank.

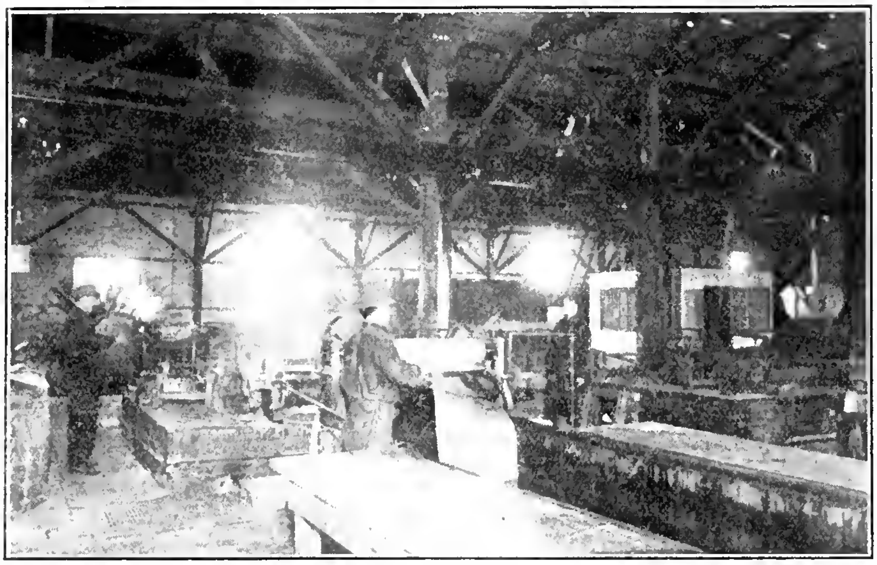
Galvanizing Process

Great care and expert knowledge is required in this operation, which consists of coating the sheets with a thin layer of zinc spelter. It will shortly be possible to obtain Canadian smelted zinc. There are two galvanizing plants installed and are operated independently of each other. Each plant consists of a "pot" constructed of brick, and having a natural gas-fired furnace underneath. The "pot" contains the spelter, one charge weighing about 80,000 pounds, and also the machine for doing the galvanizing. The pot and furnace were constructed by the company, and the machine was supplied by the Berger Mfg. Co., Canton, Ohio. An interesting feature is the C. G. E. motor controller, which has 14 speeds ahead and reverse; by this means the speed of the sheet passing through the tank can be varied, as each different gauge of metal must be coated at a speed definitely determined in advance. The motor and drive for each machine are located in a pit near the machine, and thus do not obstruct the operators. The motors are each 7½ h.p., and were supplied by the Wagner Electric Mfg. Co.

Before being galvanized, the sheets are inspected and dipped in a tank containing muriatic acid; this acid cleans the sheets, and also acts as a flux or binding medium for the spelter. The sheets are fed from the tank through a pair of 6-in. rubber rolls through a bath of salammoniac, which is a flux and floats at one end of the pot only, on top of the spelter. The sheets travel down on guides immersed in spelter through the bottom



PICKLING DEPARTMENT WHERE SHEETS ARE PREPARED FOR GALVANIZING.

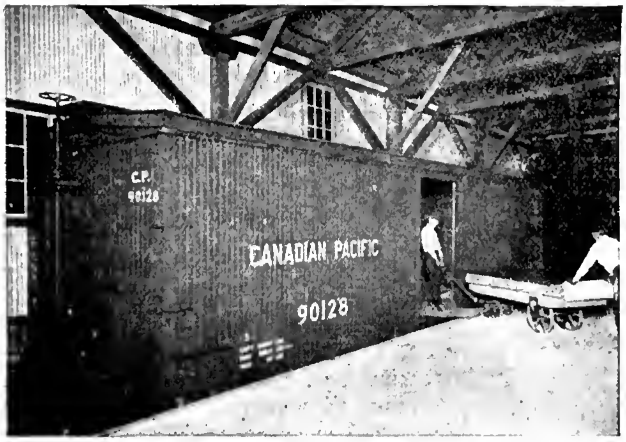


GALVANIZING MACHINE WITH FEED TANK.

rolls which carry the sheets along. The sheets then pass through another set of finishing rolls, which assist in the process, and also draw the sheets out of the pot. The speeds of the various sets of rollers vary, a feature which is carefully worked out in the construction of the drive gear. The temperature of the spelter in the pot is recorded on a pyrometer supplied by the Brown Electric Pyrometer Co., Philadelphia, Pa.

Cooling the Sheets

As the sheets leave the finishing rolls on a chain conveyor, they are carried between a series of rolls or levellers, which, as the name indicates, flattens out the sheets while hot. The sheets are then carried a short distance on another set of rollers to a table in front of the revolving cooling racks. On this table is a trip gear automatically operated, which places each sheet in position on each rack as the latter comes round. The cooling machine revolves very slowly, and, while doing so, compressed air



SHIPPING "PREMIER" GALVANIZED SHEETS.

is played on the sheets, giving to the smooth silvery surface that spangled appearance which distinguishes all galvanized sheets. The accompanying illustration will give the reader an idea as to the type of machine used for the cooling process. There are two of these automatic cooling machines installed, both having been built by the United Engineering and Foundry Co., Pittsburg, Pa. The cooling machines are operated by the motors that drive the galvanizing machines.

By the time the sheets have travelled over to the other side of the cooler they are cool. They are then taken from the racks, placed on trucks and carefully inspected on both sides for any imperfection. Any sheets that are imperfect are placed on one side, while the perfect sheets are branded. The sheets are now finished and are loaded into cars, which are inside the shop, or are bundled, weighed, and taken to the warehouse to await shipment when required.

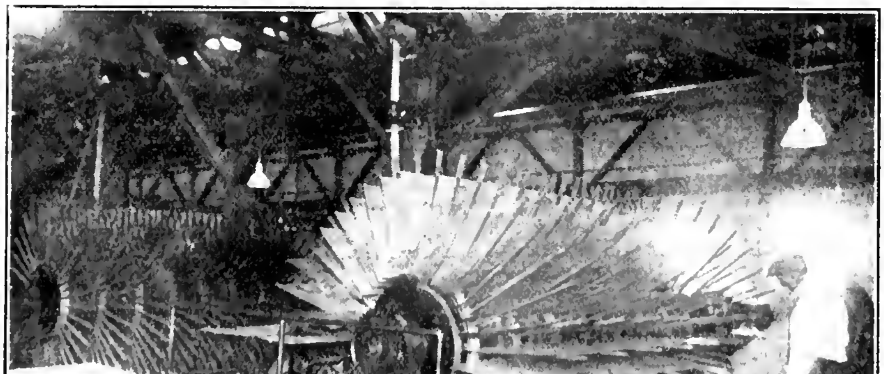
Heating and Lighting Feature

The boiler for heating the plant is located in the warehouse. The boiler is rated at 30 h.p., is of the horizontal return tubular type, and was built by E. Leonard & Sons, London, Ont. It is fired from waste heat from the galvanizing pot furnaces, but is also equipped with gas burners as a stand-by. This boiler also furnishes the steam for the pickling tanks.

Current from the Hydro-Electric system is used throughout the plant for the motors and the lighting system. In connection with the latter there are a number of 600-watt tungsten lamps installed, which give an exceptionally bright appearance to the interior of the shops. The offices are located in a separate building. On the property is a pond used for receiving the discharge from the acid tanks, a considerable saving in operating expenses being made by means of this.

Although the plant has only been in operation for a comparatively short period, the company has been very successful in producing a high-class sheet. The president and general manager of the company, A. T. Enlow, has had a lifelong experience in the sheet metal business, and is ably supported by an efficient technical staff. The company has thus been spared many of the troubles which would doubtless handicap a concern embarking on a new venture of this description under less favorable conditions.

The control of the mind as a working machine is the end of all education. This can be accomplished with deliberation.



INSPECTION DEPARTMENT AND AUTOMATIC COOLING MACHINES FOR FINISHED SHEETS.

COPPER IN AMMUNITION

AMONG the many and varied uses of copper, its consumption in the manufacture of ammunition is not the least important, as is attested by the fact that some 20,000,000 lb. of copper is used for this purpose each year in the United States alone, in spite of the small degree to which military preparation for war is here developed. Within the past few months huge orders for the ammunition required in Europe have been placed with firms in this country, many of them concerns formerly engaged in making other kinds of goods, but who are not unwilling to modify their plants and procedure in order to benefit by the high prices paid for quick delivery of the various munitions now being consumed so lavishly. It is impossible to estimate how much copper is now being used for this purpose, but some idea may be gleaned from the way in which the price of the metal has risen in the past few months, and continues to rise in spite of the efforts of the mining companies to increase their output.

When copper in ammunition is mentioned, the natural association is with the brass cartridges used for ordinary rifles. Greater interest attaches to the cartridge cases for quick-firers and field guns. The case of the cartridge for a 3-in. gun weighs 1 lb. 5 oz., while that for a 6-in. gun weighs 28 lb. 14 oz. As in a million rifle cartridges only 23,000 to 26,000 lb. copper is used, it is seen that the greater weight of the larger cartridges tends to compensate for the less frequency with which they are fired. But there are other uses of copper in ammunition. Every shrapnel shell must have a copper band about it in order to prevent the escape of the gases of the explosion past the projectile; these rings average 2½ to 3 lb. in weight per shell. The copper expands under the impact of the explosion and makes a tight fit against the sides of the gun. This saves the wear caused by the rush of the gas past the projectile and increases the power of the gun; it also makes the projectile follow the rifling better.

Every cartridge requires a primer; these are made of copper or a soft brass rich in copper. The old-style lead bullet is not suitable for use in the modern high-power rifles, so the projectile is commonly made with a hard jacket over a lead core. An alloy of 85 per cent. copper and 15 per cent. nickel is the most suitable for this purpose. The Germans use sheet-steel cases for bullets, plating them to protect them from rust. The steel is believed to wear the rifling of the barrel more rapidly than cupronickel, but does not foul it so quickly, being harder. One of the armies of Europe uses a solid brass bullet. The lead used in all projectiles, especially shrapnel, contains antimony, hence the present demand and high price of that metal.

Spelter advances with the demand for copper in war. The brass used in the making of ammunition must be of the best quality, containing about 70 per cent. copper and 30 per cent. zinc, so it will not crack in working, nor be destroyed in firing, as all cartridges are reloaded. The specifications of the United States Army require cartridges to stand twenty reloadings without failure. The reason for this is that the case of a rifle cartridge costs 1½ cents, while the complete cartridge costs only 2½ cents, thus it is good economy to reload as often as possible. In making a case, flat discs are stamped out of brass sheets of the requisite thickness. The next operation cups the disc, and by a series of these it is formed into a cylinder, "necked-down" to the shape required, and the head is finally formed from the thick metal left in the base. After each operation the brass must be annealed, as the working makes it hard and it would crack on further working. Both the copper and spelter must be pure, as impurities make the brass hard and cause it to crack. Good electrolytic copper is pure enough, but the spelter must be purer than ordinary brands, which contain too much lead for this purpose. Spelter made from the franklinite and zincite ores of New Jersey and the blende from Tennessee, which are free from lead, therefore commands a premium over prime Western. This premium has recently been large enough to warrant the redistilling of ordinary spelter in order to purify it. Another reason for using brass of the highest quality should be pointed out. Brass is used for cartridges rather than copper, because the cases must possess sufficient resilience to spring away from the sides of the gun-chamber, after firing; otherwise the shell cannot be extracted, and the gun is temporarily out of commission. This is especially important in the case of quick-firing guns. If the case splits or cracks, it will stick in the chamber.

As previously stated, all cases are reloaded. But it must be remembered that it is a long way from Bukowina to the Naugatuck Valley of Connecticut, while many shells are lost on the battlefields and will not find their way back for reloading for a long time. Orders for ammunition are being based on immediate requirements; in the event of the war being protracted the rate of consumption will probably decline, and when peace is concluded enormous quantities of scrap brass will find their way into the markets of Europe. What effect this is likely to have on post-war copper consumption it is difficult to prophesy.—Queensland Mining Journal.

LUBRICATION OF PORTABLE AIR TOOLS

ENORMOUS numbers of compressed air hammers, drills, and other portable tools are in regular service in various engineering and mining services, and it is safe to say that a very large percentage of these tools are working at less than full efficiency and wearing out unnecessarily fast owing to improper lubrication. The volume of air passing through even the smallest tool is very large, and it has several prejudicial tendencies. In the first place, it tends to blow oil away from the air valves and piston into the exhaust passage, particularly since a thin oil is necessary for these high-speed parts. It tends also to oxidize any oil which is of a "drying" nature or contains oxidizable adulterants, and any "gumming" naturally means decreased efficiency and increased wear. Finally, unfiltered air carries with it dust in amounts which will only be appreciated by those who have had experience with air filters. Unless the latter be used, particles carried by the air will be deposited in the air compressors and air tool to the detriment of glands, valves, and cylinders.

Quite a simple air filter, consisting of several layers of muslin over a wood or wire framework, is sufficient over the air intake of the compressor, and efficient filter nipples are on the market for instant connection in any compressed air line supplying individual tools. By thus keeping dirt out of the tools half the battle of efficiency and durability is won. For the rest it suffices to give the working parts of the tool a thorough washing with paraffin once a week at least and once a day if the service is very heavy; and to lubricate liberally and regularly during working. A thin machine oil is suitable for hammer pistons and valves, and a supply should be given every hour or so during regular working. Gear and crank cases should be filled with high quality grease once a shift. In the air compressor itself it is best to use one of the special graphite lubricants, since accumulations of oily matter in air containers and pipe lines are apt to cause spontaneous combustion and explosions.

YOUR GREATEST work—a work in which there can be no failure for the earnest and sincere man—your greatest opportunity in life, will be found shoulder to shoulder with your fellow-man, doing the things good for all of us. Thus in serving yourself, you will serve your neighbor, your community, your state and your nation. You will be doing your work in helping to perpetuate the civilization of the entire world.

Presses for the Manufacture of Shells and Shell Cases *

By William Rodger **

The question of the best type of press to install for the production of steel shell forgings or brass cartridge cases appears to be more or less an open one. In the discussion following the reading of the accompanying paper, both power and hydraulically operated presses were championed, although operations of varying nature occasionally call for discrimination.

IN connection with the manufacture of cartridges and shells, the question raised is whether an hydraulic or power type is the most economical and efficient press for the manufacture of cartridges and shells. The writer is fully aware that economy in some cases is unattainable if the plant has been laid out for the manufacture of material other than the work above designated, but by careful attention to the lay-out, economy can be attained. It is purposed in this paper to deal with the following types of hydraulic and power plant presses:—

1—Steam pump press.
2—Motor driven pump press.
3—Motor driven power press.
4—Direct steam press.

Steam Pump Press

Boilers are required to generate steam to drive the pumps, and the pumps must be sufficiently large to supply the water at the required pressure and velocity to keep up the accumulator when the presses are in operation. It is absolutely essential that a receiving tank should be installed, having a direct connection with the water main and in order to prevent the pumps drawing air, care should be taken to ensure a sufficient height of water being maintained above the suction pipe at the pump. The water so pumped into the accumulator, performs the work in the press and exhausts back to the receiving tank, thus setting up a standard of economy in the supply of water. A stop valve should be fixed in the main intake to close the water supply when the pump is not in operation and thus guard against an overflow of the tank. In this type of press, economy in steam power can be attained by the use of a trip valve operated automatically, which cuts out the steam when the press is not in operation.

It is policy, when installing this type of press, to make the pumps 25 per cent. larger than actually required, and the writer is also of the opinion that it indicates good judgment on the part of the engineer, as at times the pump is liable to give out with an overload on the press. The pressure of water per square inch is obtained by the steam pressure on the piston, and the load is transmitted through the crank shaft to the plungers; consequently any pressure per square inch can be attained. An hydraulic intensifier is capable of transforming low pressure, as from a main, into a useful hydraulic pressure, therefore, by this means, additional pressure can be transmitted to the accumulator.

The accumulator is undoubtedly the most important adjunct in hydraulic transmission, constituting an artificial head, by which the pressure of water is transmitted to the press by the aid of

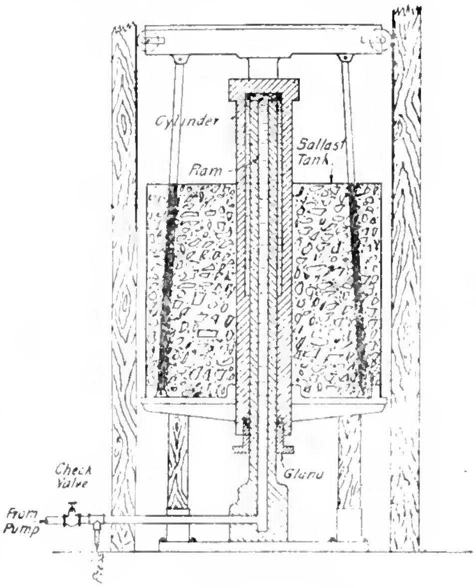


FIG. 1. ACCUMULATOR.

material in addition to water power. Fig. 1 illustrates an accumulator having a ram 21 feet long, 12 inches diameter and 4 inches thick. The lower part of the ram is cast with a tapered collar 14 inches in length having a diameter sufficiently large to ensure a pressure of not more than 545 lbs. per square inch on the supporting surface; there is also an elliptical boss on collar for pipe connection. From the collar to the lower extremity, the diameter of the ram is 18 inches and the length 21 inches. It is machined to gauge to fit into the bottom base. The base is made of cast iron about six feet square and six inches thick, and is bored to gauge to receive the ram.

The cylinder is a large cast iron pipe closed at the upper end and surmounted by a cross-head to which are attached stay-rods leading to the floor of the ballast drum. The lower flange of the cylinder carries the ballast drum, and immediately below this flange, the cylinder is extended to form a stuffing box. The gland is also made of cast iron, being cast in halves in order to facilitate packing.

The ballast drum is about ten feet in height, having a diameter also of ten feet. It is made of quarter inch plates riveted together, having 4 x 4 x ½ angles at the bottom and 3 x 3 x ½ at the top. The lower plate of the drum is of ¾ inch boiler plate made in halves, having tees riveted at the bottom, radiating from the centre to the outer edge to which the stay rods are pinned. It is essential that the stay rods should be made strong to stand the stress due to weight of the ballast in the drum.

On a ram 12 inches diameter, having a similar size of drum, the quantity of ballast required to maintain a pressure of 1,500 lbs. per square inch would be approximately 145,000 lbs. The ballast preferred for this purpose would be iron cuttings and punchings. The following is the ratio of various materials which could be used as ballast:—Pig iron, 6.25 cubic feet per ton; broken stone, 17.2; clay or earth, 18.5; bricks, 22.2.

The accumulator requires to be fixed on good concrete foundation, about six feet deep by eight feet square, made amply strong to carry the load and the weight. Between the accumulator and the pump is placed a by-pass with pilot valve. This is operated automatically by the upstrokes of the ram, which contacts with a weight connected with a wire rope travelling over a pulley fixed to the roof or girder of the building, and joined to lever of the pilot valve, thus reversing the action of the water and closing the connection from the pump to the accumulator. The service pipe to the press, the absorber, and the check valve are fixed between the by-pass valve and the accumulator. The absorber is used to reduce the shock when accumulator is in operation and in turn the check valve prevents the return of the water to the pump.

Hydraulic Press.

The position of the presses should be known relative to the pump and accumulator in order that the pipes may be arranged to eliminate right angle bends, thus preventing sudden shocks and bursting of pipes, which would materially re-

*From a paper before the Canadian Railway Club, Montreal.
**Elevator Draftsman, C.P.R., Montreal.

tard the output. It is desirable that the pipe leading from the pump to the accumulator should be larger than the pipes leading from the accumulator to the presses.

A loss of power occurs when flowing water passes round a sharp bend or angle, or when it is subjected to sudden force. When easy bends are used there is practically no loss of energy in this direction, but with sharp bends and elbows the loss may be greatly increased. These facts point to the necessity of avoiding, as far as possible, all sharp edge inlets to ports. The best results are obtained when the water passages from the pump to the press are designed so as to ensure all the changes of direction and velocity being as gradual as possible.

If a hydraulic plant is well designed, the loss of useful effect between the pump and an accumulator properly packed, is but little. After various researches the writer found that Mr. Tweddell had compiled some careful records of the working of two pumps delivering water to the accumulator. What

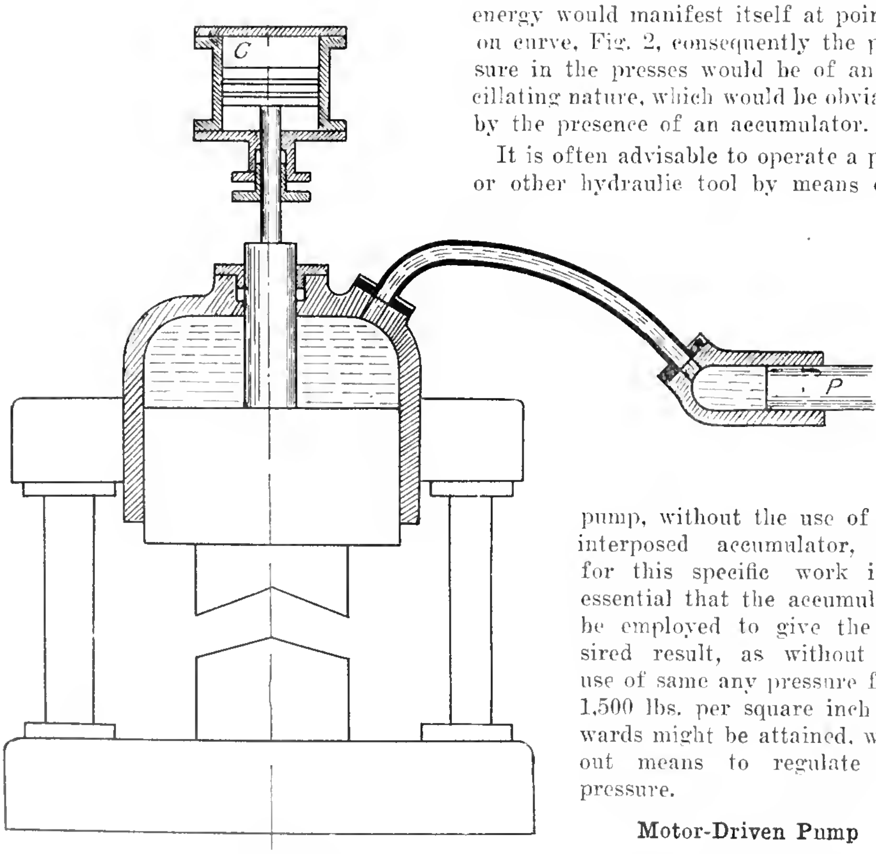

FIG. 3. "ALLEN" PRESS.

he found to be the theoretical delivery for twenty strokes of one pump to raise the ram to the exact height was 1,694 cubic inches of water, whereas the actual delivery was 1,614 cubic inches only, consequently a loss of 4¾ per cent. With both pumps working for a similar number of strokes, the theoretical delivery was 3,388 cubic inches, whereas the actual was 3,278 cubic inches, showing a loss of 3¼ per cent. only.

At the time these experiments were made, it was noticed that the ascending pressure in the accumulator indicated 1,250 lbs. per square inch, while the de-

FIG. 2. PUMP DELIVERY CURVE.

scending pressure indicated 1,225 lbs. per square inch. Thus, it will be observed, in the ascending stroke, in addition to lifting the load, the pumps had to overcome the friction, and the descending friction, as will be readily appreciated would be half the difference of pressure in both instances, i.e., 12½ lbs. per sq. inch, equivalent to one per cent. of the total pressure.

In the manufacture of cartridges and shells, the writer considers that the use of an accumulator is indispensable. To illustrate this point; should a triplex pump, which gives a more even flow of water pressure, be used, a certain loss of energy would manifest itself at point A on curve, Fig. 2, consequently the pressure in the presses would be of an oscillating nature, which would be obviated by the presence of an accumulator.

It is often advisable to operate a press or other hydraulic tool by means of a pump, without the use of any interposed accumulator, but for this specific work it is essential that the accumulator be employed to give the desired result, as without the use of same any pressure from 1,500 lbs. per square inch upwards might be attained, without means to regulate the pressure.

Motor-Driven Pump

This type of hydraulic plant is operated by a steam-driven generator which supplies current to the motor driving the power pump. The electrical generator is driven by a high-speed engine, having a short cut off, which consequently will use less steam and consume less coal than a high pressure steam pump. This class of engine will use steam at the rate of 10.8 to about 20 lbs. per i.h.p. hour, while a steam pump working at 150 lbs. boiler pressure would use approximately 80 lbs. per i.h.p. hour. Hence the motor driven pump has the advantage over the direct steam pump, and the effect is a saving of four to eight times, which would more than cover the cost of the auxiliary plant.

The most efficient power pump that will overcome the trouble due to uneven flow of water is the triplex pump, for in this type the pulsations overlap each other, the cranks being set to 120 degrees apart, in such manner that the combined discharge from the cylinder is practically uniform in quantity and pressure.

Motor Driven Power Press

This type is purely mechanical, and is operated by an electrical motor arranged in any suitable way. There are many ways of driving the power press, and it is the opinion of the writer that the best method is by a motor-driven countershaft, which obviates the necessity of a special self-starting rheostat.

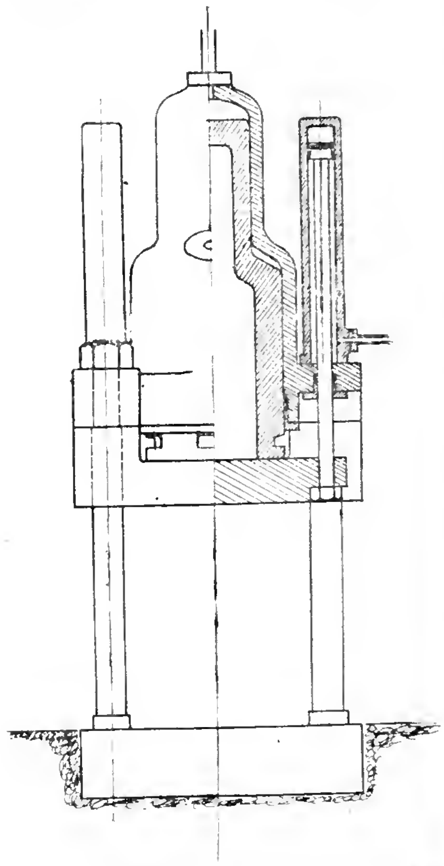

FIG. 4. TANDEM CYLINDER HYDRAULIC PRESS.

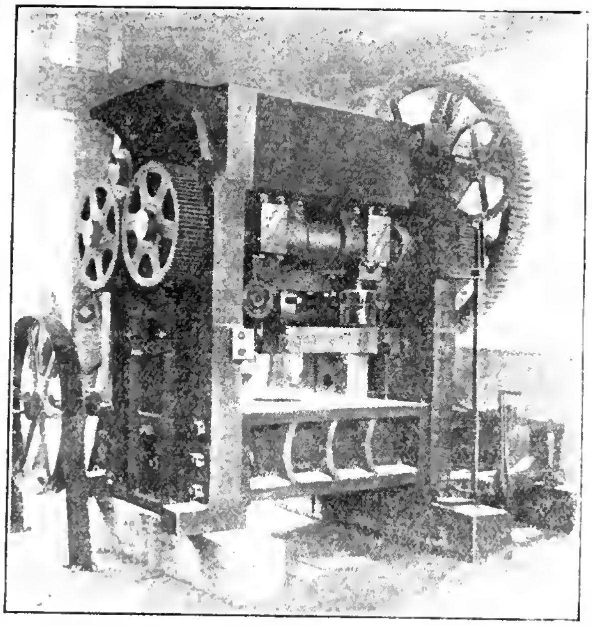
In connection with the above type of press, to obtain an even pressure, Taylor & Challen, England, found it necessary to introduce four cranks with connecting rods operated by two crank shafts, and from the illustration it will be seen how the drive is effected.

The other type of press is oper-

ated by motor, the power being transmitted through a worm. The worm is screwed right and left hand, with a crosshead placed on each side, and the moving table has a vertical guide bar fixed thereon, which slides through the top platen. The vertical motion is made by four links, two of which are fixed to the top platen, and two to the guide bar, and connected to crosshead on either side. When the worm revolves the crosshead travels inwards towards the centre and presses the table on the material and vice versa releases the pressure.



FOUR-CRANK POWER PRESS BY TAYLOR AND CHALLEN, LTD.

Direct Steam Press

This type would not be suitable for shell or cartridge making, as it is not possible to attain the required pressure per square inch at the back of the piston. The expense likely to be incurred in the installation of a high pressure boiler for this work would be far too great, for, in addition, the introduction of a crank system would be required to attain a pressure of 800 lbs. per square inch.

Having dealt with the four types of presses, the writer will endeavor to demonstrate the superiority of the hydraulic press with a motor driven pump, as compared with the steam pump press and a motor driven power press. Before entering into details it will be interesting to note the records made by Professor Robinson:—

Flow of Solids.—Hydraulic forging has revolutionized the treatment of large masses of iron and steel by enabling immense pressure to be brought to bear on hot metal plates, or masses of iron and steel. By means of fluid compression, ingots are produced of a soundness which was hitherto impossible of accomplishment, and by hydraulic pressure masses of metal can be squeezed into required shapes far better than by blows from a steam hammer.

The employment in recent years of iron in increasingly large masses has involved the consideration of how the continuity of the fibre can be maintained and what the conditions are which have to be observed in order to prevent break of continuity, or a diminution of the calculated strength of the mass. Investigations by the late Mr. Tresca, recorded in the Proceedings of the Inst. of Mechanical Engineers (dated 1868 and 1878), have thrown light on the subject and would be of practical value with regard to forgings made under pressure or squeezed, instead of being forged under a hammer and formed by means of blows. Mr. Tresca applied the expression "the flow of solids," and the singular fact he established indicated that an entirely new branch of observation had been opened out, to which M. De St. Venant gave the name of Plastic Dynamics.

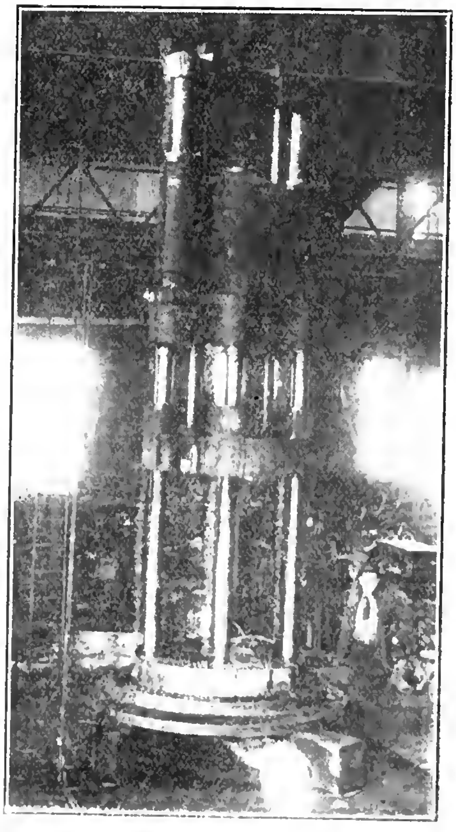
Presses for 18-Pounder Shrapnel Shell Forgings

The presses for the manufacture of 18-pdr. shells are fixed on a concrete foundation surmounted with a cast iron base through which four steel columns, eight inches diameter, pass, and are held at lower extremity with solid hexagon nuts. These columns support the main cylinder by means of a collar, and are also held in position by solid hexagon nuts. The columns also guide the moving table which is bushed in halves to facilitate the placing or the replacement of the bushes, and a retaining ring is used to hold the bushes in position. The draw-back cylinders are bolted to the main cylinder and the rams are made fast to the crosshead and connected to the moving table by two columns of about five inches diameter. In this manner the pressure is released from the tools.

The height of the press complete is approximately 21 feet and there are two classes: The first has a capacity of 350 tons pressure, the second having a capacity of 225 tons only. The presses are constructed having the main ram common to both, while the difference of pressure is accounted for by the diameter of the draw back cylinders, which in this instance would be 8 and 10½ inches, respectively. The stroke of the ram in the former press is thirty-six inches and in the latter forty-five inches.

In the production of heavy forgings from large ingots of mild steel, it is essential that every part of the ingot should be equally worked if the resultant forging is to be homogeneous in structure. Where a steam hammer is used, the energy of the blow is absorbed in producing distortion of the outer layers while the interior is practically unaffected. This disadvantage is overcome by the use of the hydraulic forging press with its slow and powerful compression, it gradually supplanting the steam hammer for the production of very heavy forgings.

The "Allen press (Fig. 3) works on a very ingenious principle. Here a pressure accumulator is necessary, likewise the valves in the high pressure water column. For its operation a low water pressure supply, approximately of 200 to 300 lbs. per square inch, is necessary, and during the idle part of the stroke this follows up the ram, the high pressure connecting pipe being kept full. In the meantime, when the pressure is required, this supply is cut off and communication is made with the high pressure pump. The pump has no valves, hence the ram has a continuous up and down motion, the water column simply following the motion of the pump plunger. The momentum of this column thus has a useful effect in increasing pressure on the ram at the end



HYDRAULIC PRESS FOR PRODUCTION 18-PDR. SHELLS.

of the working stroke. A steam cylinder is usually provided for lifting the ram.

Fig. 4 shows a type of hydraulic press having two cylinders with two draw backs, to which the pressure is supplied by an accumulator and an intensifier. It can be operated for three distinct loads, and is constructed to carry any load. The top cylinder is of 21 inches diameter and the lower cylinder has a diameter of 36 inches. It will be readily seen that this type of press is particularly advantageous and can be profitably adapted to the manufacture of shells, heavy forgings, cartridges, etc.

The hydraulic press has the advantage over the power press, as it is necessary for the latter to have some means of bringing down the moving table, either by a crank or toggle arrangement. A power press with crank, having a short travel similar to press manufactured by Taylor & Challen (already described) would not be practical for this specific work, as a stroke of 36 to 45 inches is required. The crank motion also has a tendency to fly out on a tangent, thus causing the tools or dies to get out of line. With the toggle arrangement a similar trouble would be experienced, although the travel required would be attained.

Cartridge Case Heading and Indenting

In the manufacture of cartridge cases presses are built for indenting and heading 18 pdr., and 4.5 sizes. It was found for this particular operation that the pressure required was 800 tons. The cylinder of the press is made of cast steel, similar in shape to a goblet, with a cast iron ram of 36 inches diameter, the lower portion being 8 inches diameter only, to serve as a guide for the main ram, in which a hole three inches in diameter is cored to the bottom of the guide, in order that the benefit of 36 inches area might be derived. The four columns are carried by four lugs cast on the upper part of the cylinder, the columns being surmounted with a cast steel platen.

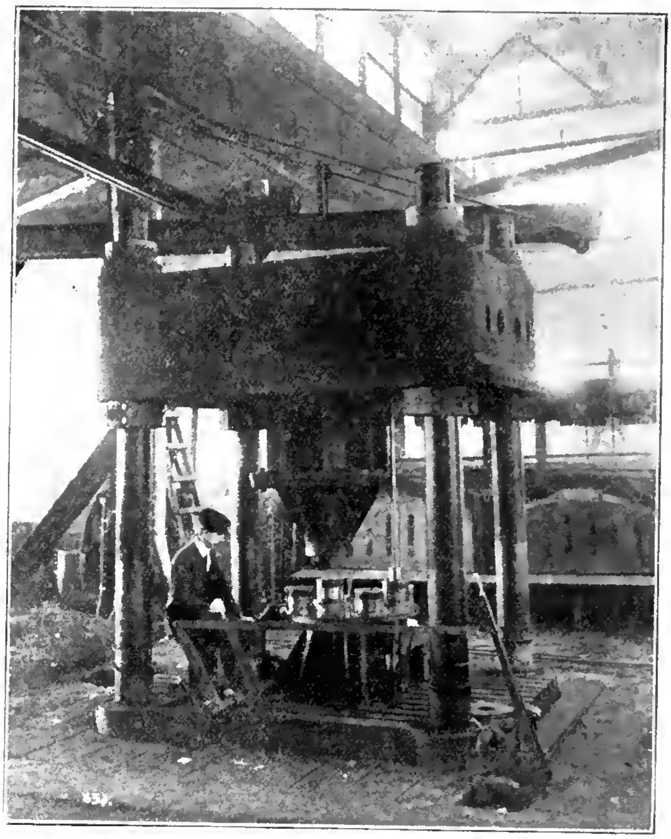


FIG. 7. 500-TON HYDRAULIC PRESS.

A fixed table is bolted to the top of the ram above which a movable table is fixed, riding on ball-races, for the purpose of facilitating the operation of bringing the dies to dead centre; the dies being kept in position while indenting and heading by notches cut at equal distance on the outer edge of the revolving table.

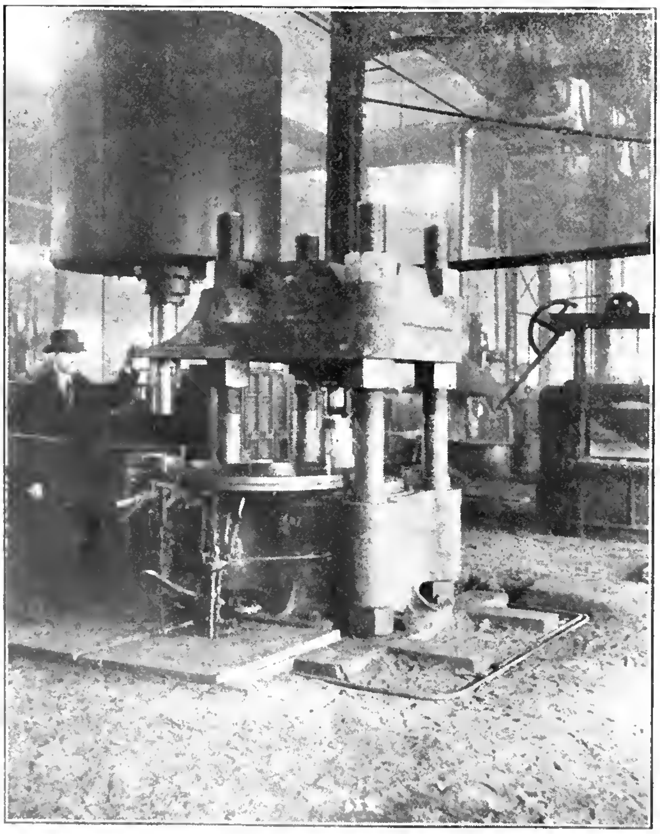

FIG. 6. 800-TON HYDRAULIC PRESS FOR CARTRIDGE CASE HEADING AND INDENTING.

It is very important that the work of indenting and heading the cartridge be accurate, and the press most suitable for this class of work is without doubt the hydraulic, as although the required pressure can be attained by the power press, its accuracy cannot be relied upon. The material in present use is bronze and the cartridge on completion of the operation of the hydraulic press is isotropic. In other words, the stress is equal, both lateral and vertical. This could not be attained by the power press, because of unequal pressure, its agencies being contrary to downward motion, and the result an irregular section.

1916 FOUNDRY EXHIBIT AT CLEVELAND

AT a recent meeting of the executive committee of the American Foundrymen's Association at Cleveland it was decided to receive bids for the conduct of the exhibition of foundry machinery and supplies which will be held in connection with the convention at Cleveland next year. For several years the exhibition has been under the control of the Foundry & Machine Exhibition Company. It is understood that bids are to be opened Nov. 13 at Cleveland, and that the successful bidder will manage the exhibition for the foundrymen, the net profits to go to the associations and the exhibitors.

ECONOMICAL VANADIUM IRON CASTINGS

THE problem of cheapening production without impairing quality is one that is always with us, and it will be of greater importance than ever in the years of industrial rivalry following the war. The use of the cheapest suitable materials is by no means the least fruitful of the many possible fields of economy, and in this connection it is interesting to note

the results of a series of tests recently conducted by Prof. Fitch on vanadium castings. It appears that a pig iron containing silicon 2.00; sulphur, 0.02; phosphorus, 0.58; manganese, 0.69; carbon, 3.62 (0.55 combined); titanium, 0.022; and vanadium, 0.04 per cent., has unusually high scrap-carrying abilities and that nothing is to be gained from using a mixture of pig iron and scrap containing a large proportion of pig iron, even for automobile cylinders, or other work requiring soft, dense, machinable metal.

A series of tests was conducted on castings containing from zero to 80 per cent. scrap of the following composition: Silicon, 1.74; sulphur, 0.09; phosphorus, 0.49; manganese, 0.36; carbon, 3.30 (0.75 combined); titanium, 0.04; vanadium, 0.01 per cent. It was found that the test data lay between the following limits for specimens with from 20 to 80 per cent. scrap, the bracketed figures referring to pure pig specimens: Tensile, 22,000-26,500 (25,200) lb.; modulus of transverse rupture, 48,000-55,000 (50,600) lb. per sq. in.; deflection (12-in. centres), 0.086-0.116 (0.097) in.; shrinkage per foot, .11-.125 in. (.11 in.) in green sand and .125-.15 in. (.13.) against a chill; scleroscope reading (tool steel 100) 35.3-36.1 (36.3); pouring temperature, 2,125-2,475 deg. F. (2,280 deg.). These figures give a good indication of the scrap-carrying capacity of the pig and of the strength and resiliency of vanadium castings.

Using pig of the composition stated and scrap not differing much from the above analysis, it is recommended that a 50 per cent. mixture be used for all but heavy castings (wherein no part is less than 2 in. thick). Sixty per cent. gray iron machinery scrap gives good medium castings, and no less than 80 per cent. scrap can be used for heavy casting. Castings of these compositions are claimed to be easy to machine, soft and close grained, and easily susceptible to high polish. The possibilities of high-scrap, vanadium castings are distinctly worth bearing in mind for practically all classes of work.

THE CAUSE OF RUPTURED FLY-WHEELS

WHEN a flywheel cools after casting, the rim and central boss remain hot much longer than the arms, and thus continue to shrink after the arms have set rigidly. This is where the mischief occurs. The shrinking rim and boss subject the arms to mixed stresses, and the arms resist the shrinkage of the rim and boss. The net result is that, though the wheel does not fracture at the time of cooling, yet it is in such a condition of internal stress of tension that a slight excess of speed of revolution above the normal is liable to fracture it. The majority of the fractures of flywheels originate from this cause alone. A great deal can be done, however, in proportioning the rim, arms and boss, or by hastening the cooling of the rim and boss, and delaying that of the arms, so that the cooling shall take place in about equal times. This is properly done in cast iron flywheels, but as there is always an element of risk, the practice has grown of abandoning such wheels in favor of those built up in separate pieces, bolted together, and in another direction of using arms of wrought iron in rims and bosses cast around the ends of the arms. Therefore, though cast iron is used for wheels of small and moderate dimensions, the composite wheels are almost invariably used for those of large dimensions.

Chairman Cammell, Laird & Co., Birkenhead and Sheffield, England, who has arrived in Canada to assist in the work of organizing munitions production.

MILL CONSTRUCTION

MILL construction consists in so disposing the timber and plans in heavy and solid masses as to expose the least number of corners or ignitible projections to fire, to the end also that when fire occurs it may be most readily reached by water from sprinklers or hose.

It consists in separating every floor from every other floor by incombustible stops—by automatic hatchways, by encasing stairways either in brick or other incombustible partitions so that a fire shall be retarded in passing from floor to floor to the utmost that is consistent with the use of wood or any material in construction that is not absolutely proof against fire from any source.

It consists in guarding the ceilings over all specially hazardous stock or processes with fire-retarding material, such as plastering laid on wire-lath, or expanded metal, or upon wooden dovetailed lath, following the lines of the ceiling and of the timbers without any interspaces between the plastering and the wood; or else in protecting ceilings over hazardous places with asbestos air-cell board, sheet metal, "Sackett" wall board, or other fire-retardant.

It consists not only in so constructing the mill, workshop or warehouse that fire shall pass as slowly as possible from one part of the building to another, but also in providing all suitable safeguards against fire.

Vertical openings throughout buildings as far as stairs and elevators are concerned, rapidly communicate fire to all storeys. With buildings of considerable height or combustible contents, this is likely to result in fire conditions beyond fire department control. All such floor openings should be enclosed in brick-wall shafts, crowned by thin glass skylight, and extended through roofs having fire doors with openings to storeys. Enclosed vertical openings are considered to be the most prominent features contributing to fire cost and loss of life. Neglect to guard these openings is common. Pains should be taken to rectify this condition in all existing buildings as well as in those hereafter erected, particularly if of mercantile, manufacture or storage occupancy.—Ex.

MUNITIONS CLASSES IN SCOTLAND

CONSIDERABLE interest is being evinced in these classes, and already between 1,200 and 1,300 applications from intending students have been received by the governors of the Glasgow Technical College, although the classes must, for the present, be limited to thirty workers at a time. At the moment this is the total number of lathes available, and, withal, larger engineering works being so fully occupied on Government contracts, the only possible chance of increasing this number is to get some on loan from smaller tradesmen who might be able to spare them.

WATER meters in London, Ont., numbered 2,562 January 1, 1915, an increase of 486 during the previous year. Only 17 per cent. of services are metered, although 24 per cent. of the water consumed passes through meters and furnishes 40 per cent. of the revenue. Each inhabitant of this town of 56,000 population consumes on the average 81 Imperial gallons per day and the cost of the water is $34.15 per million gallons.

PROGRESS IN NEW EQUIPMENT

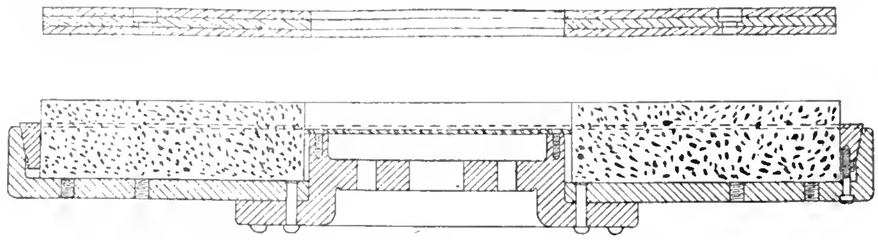
A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

WIDE FACE RING WHEEL GRINDER

An improved flat surface grinder of the ring wheel type has just been placed on the market by Charles H. Besly & Co., 120 North Clinton St., Chicago. This machine is called a Besly Wide Face Ring Wheel Grinder, and as shown in Fig. 1, is similar to the single spindle lever feed Besly disc grinder except that for roughing off scale and excess stock one end of the spindle is equipped with a pressed steel chuck holding a wide face vitrified ring wheel. This grinding wheel has 8 inches to 10 inches width of grinding face, so that work may be allowed to "float" on this broad face, while grinding; same as is done on the usual steel disc wheels covered with cloth abrasive discs.

These vitrified grinding wheels are more efficient and economical than cloth back abrasive discs for heavy rough grinding on scale; in fact, large rough work may be accomplished on the wide face ring wheel grinder which cannot be done at all on the ordinary disc grinder.

Besly grinders have, heretofore, been equipped with ring wheel chucks for rough grinding, but with comparatively narrow-faced ring wheels which made it necessary to rigidly clamp any work which was to be ground. The advantage of the wide face ring wheel as compared with the original narrow face ring wheel is that much work may be "floated" against the wide face wheel as in disc grinding and ground without clamping. This saves time in chucking. There is a further saving in the time of grinding because with the wide face ring wheel more cutting points are in action, as it grinds all over the face of the work at once—side swiping. The opposite end of spindle is equipped with the usual steel disc wheel set up with cloth back abrasive discs for finish grinding.



PRESSED STEEL CHUCK WITH CLAMP RING AND LAMINATED PACKING PLATE.

Chuck body is pressed steel, double riveted to a cast iron centre. Construction of this centre is such that spindle bearing projects into the chuck, thereby minimizing overhang. Chuck body is drilled and tapped from the back to receive headless threaded plugs for balancing. Grinding wheel is held in the chuck by pressure over its periphery. This pressure is applied by means of a wrought steel tapered clamp ring, passing around the grinding wheel. This ring is drawn into the tapered chuck body by means of clamp screws operated from the back of the chuck body. A suitable steel plate is provided to fit the centre hole of the grinding wheel and guard the heads of the screws which hold the chuck on the grinder spindle; so there are no external projections. This makes the chuck especially safe. As grinding wheel wears away, it may be set out in the chuck by means of a laminated wood plate supplied with the chuck.

The Besly wide face ring wheel grinder is built in two sizes: No. 17 carrying vitrified grinding wheel 24-inch diameter, 8-inch hole, 8-inch width of grinding face, illustrated in Fig. 1, and No. 16 carrying vitrified grinding wheel 30-inch diameter, 10-inch hole, 10-inch width of grinding face. All ring wheels are 3-inch thick when new and may be worn down to 1 inch in thickness.

Examples of economical surfacing are shown in Figs. 2 and 3, the former showing grinding of pillow blocks and caps. The 6 in. x 13 in. bottom surface of the cast iron pillow block was formerly done on a variable speed, motor driven shaper, using high speed tools to the limit of their capacity. In order to make this suitable for grinding instead of shaping, the pattern was changed. Very little stock was left for finish, and surface

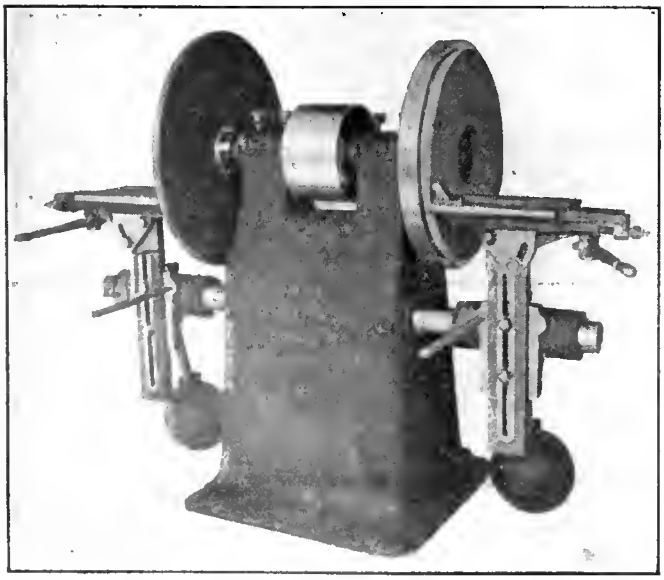


FIG. 1. NO. 17 GRINDER WITH 24-INCH DIAMETER WHEEL.

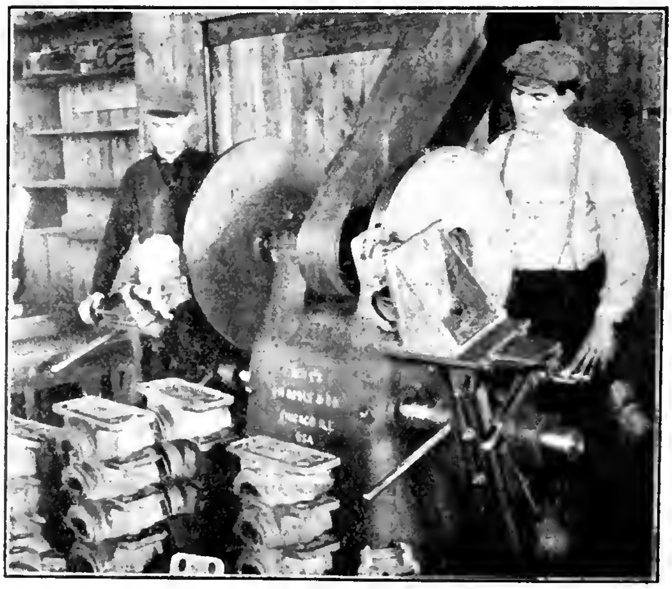

FIG. 2. GRINDING CAST IRON PILLOW BLOCKS AND CAPS.

was recessed in molding to facilitate grinding. By a little care on the part of the moulder, these castings came to the grinder with a maximnm of 1/16 in. stock for finish.

The No. 17 Besly wide face ring wheel grinder roughed and finished these surfaces, to size and flat—tested on surface plate, in less than two minutes. Former time on shaper was about twenty minutes. Allowing for careless moulding, necessitating the removal of ⅛ in. of stock, the grinder accomplishes the work in three minutes as against 20 minutes for the shaper, this time covering all work, floor to floor, including surface plate test. It will be noted that these heavy pillow blocks and caps are ground without rigid chucking—the work "floats" against the grinding wheel both in roughing and finishing operations.

Referring to Fig. 3 which shows grinding of automobile gear shifter covers; these castings are malleable iron and rather frail. As they are ground without rigid chucking, there is no chance to distort the casting as when rigidly clamped for milling.

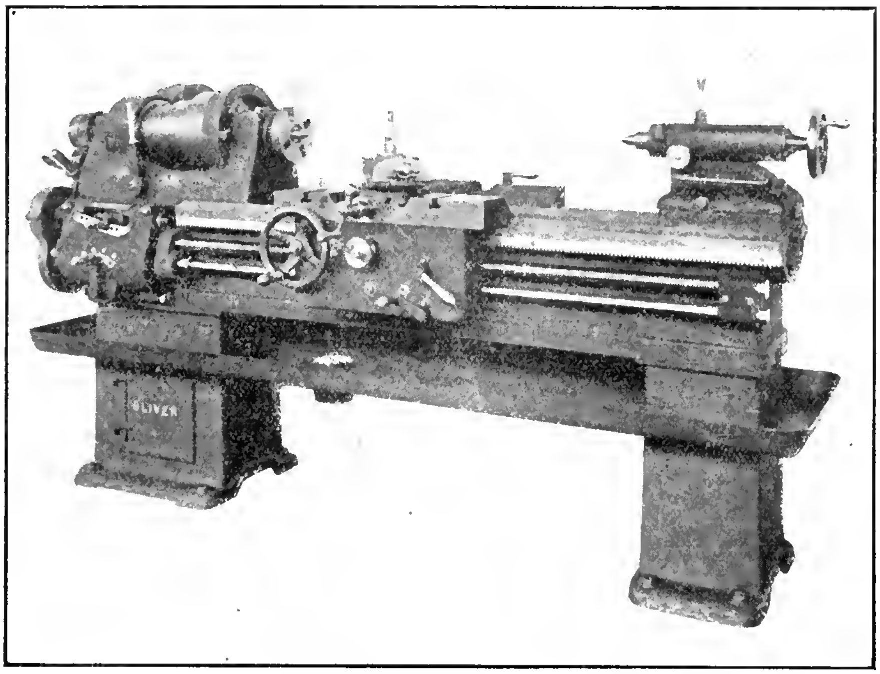
The grinder workholder is very simple. The work rests loosely on three studs projecting from the face of the angle plate. The work is located and supported on this three-point bearing by means of four studs projecting from the angle plate. The time on this job is 200 grinding operations per hour, per operator, or 100 castings roughed and finished per hour, per operator. As machine accommodates two operators, the production per machine is double that above mentioned. The geared lever feed work table used on this Besly grinder gives the operator a leverage of 20 to 1, so that with a very slight pressure of the operator's hand, the work is forced against the grinding wheel with sufficient pressure to secure maximum grinding efficiency.

To secure the best results, it is necessary to use care in designing patternmaking and moulding, so that the work may come to the grinder with the minimum amount of stock for finish, and large surfaces should be relieved to facilitate grinding.

FIG. 3. GRINDING SMALL MALLEABLE IRON CASTINGS.

16 IN. HEAVY DUTY ENGINE LATHE

THE 16-in. "Oliver" engine lathe embodies in its construction a number of new ideas in design. It is built with ample power and is quite rigid for heavy and fast cuts.



16-INCH HEAVY DUTY ENGINE LATHE.

The headstock is of three-step double back-geared type, using 3¾ in. wide belt. The spindle is large in diameter, with long bearings, lubricated by means of felt wipers feeding from large pockets. Spindle is of special high carbon steel accurately ground. The cone pulley is so designed as to carry a large oil reservoir, which provides lubricant at all times. The drive pinions for the back gears are one solid forging made of special high carbon steel and pressed into the cone pulley, keyed on, and reinforced by three filister head screws. A replaceable bronze bushing gives the proper bearing for the spindle in these gears. Thrust is taken against the front end of the rear bearing housing on a hardened and ground steel collar.

The bed is of very liberal proportions, being 7 ft. 2 in. long x 13 in. deep x 15 in. wide, and is strongly reinforced by boxed sections. The supporting columns are so placed as to allow no overhang at the end of the bed, and they are made wide so as to shorten the span of the bed between the columns. Saddle carrying cross slides to the post and apron is unusually heavy and generous in its measurements. It is 7 in. wide at the bridge and a 24½ in. bearing on the shears. Cross slide and compound slide are both provided with taper gibs to take up wear, and both screws for

this slide are indexed to read to .001 inch.

The apron is cast in one piece, and provides a double bearing to all gears.

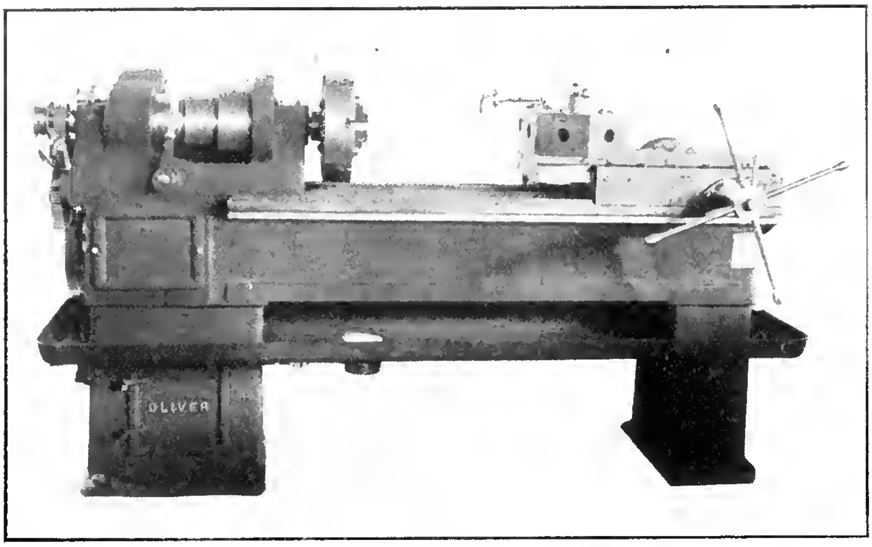
The tailstock spindle is of the same material as the hearstock spindle and accurately ground. Tailstock is clamped to the bed by means of a single heavy cast iron clamp operating the whole length of the tailstock, and secured by two bolts diagonally placed, which provides one of the best methods yet adopted for locking a tailstock. Tailstock casting is not split, but the spindle is locked by means of a clamping lever acting on double nuts, machined to fit perfectly to tailstock spindle.

The gear box for the quick change gears is very compact, requiring only two levers to obtain the thirty-two threads, ranging from three to forty-six per inch. Feeds, thirty-two in number, range from .0076 in. to .111 in. per revolution of spindle. All gears and shafts in the gear box are lubricated from but two oil cups, and there is no multiplicity of oil holes to become clogged with dirt. Gears are all steel machine cut. The gear box is so arranged that part of the box extends into the bed and projection beyond the front of the bed is reduced to a minimum, making a very compact drive. All shafts in the gear box are bronze bushed.

For lathes requiring turret, the tailstock, change gear box, apron and saddle are omitted, and the turret base, slide and turret are placed upon the bed. By means of suitable gearing the turret is connected positively to the spindle, and may be operated by power feed if desired. Change gears supplied with a machine thus equipped, allow four feeds, viz.: .010 in., .012 in., .015 in., .018 in. per revolution of spindle. To change to hand feed it is simply necessary to trip the power feed lever, dropping the worm out of mesh with the worm wheel. The diameter of the turret across the flat is 12 in. The bore for the tools is 2 in., and on each face four holes are tapped to secure special tool holders or other special equipment as desired. The turret head revolves upon a very large stud fitting it exactly, so that it is not necessary to use the clamping lever at each operation unless heavy cuts are being taken. The revolving head is of hexagon shape, giving better results for box tools. By forcing the turret slide back by means of the hand wheel the locking plunger is automatically released and the head revolved to the next station. The turret is self-indexing, the locking plunger being tool steel kept in line with taper gibs and seating itself in a hardened steel ring underneath the turret. The feed shaft is keywayed for 30 in. from the end, permitting the whole turret mechanism to be moved up close to the headstock if it is necessary to machine short work.

The equipment for the turret lathe consists of double friction countershaft, pump and piping and flexible hose with steel chip and drain pan, centre bushing and knock-out plug, and one No. 4 Morse taper centre and all necessary wrenches. (Chuck not included.)

Equipment for the regular engine lathe consists of double friction countershaft, tool post, 7 in. face plate, centre bushing and knock-out plug, pump, piping and flexible hose, steel chip pan, two No. 4 Morse taper centres, and necessary wrenches.



16-INCH LATHE FITTED WITH TURRET.

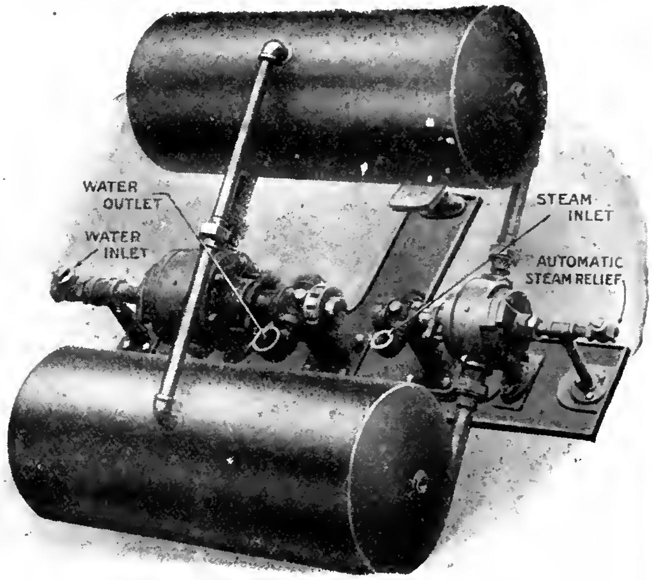
The principal specifications of this lathe, which is the product of the Oliver Machinery Co., Grand Rapids, Mich., are as follows:

Swing-over carriage	$10\frac{1}{4}$ in.
Swing-over shears	$17\frac{1}{2}$ in.
Length of bed	7 ft. 2 in.
Distance between centres	$38\frac{1}{2}$ in.
Front spindle bearing	3 in. x 5 in.
Rear spindle bearing	$2\frac{3}{8}$ in. x $3\frac{3}{4}$ in.
Tailstock spindle diameter	$2\frac{1}{8}$ in.
Tailstock spindle travel	6 in.
Hole through spindle	1 5/16 in.
Countershaft pulleys	12 in x 4 in.
Countershaft speeds	180-220 r.p.m.
Weight on skids	3,150 lbs. net.

DUPLEX STEAM TRAP

THIS Duplex Return Steam Trap is designed to fill all the requirements where a reliable and inexpensive method of handling condensation is necessary. It receives the water of condensation from whatever source and automatically delivers it into the boiler, or elevates it to a heater at practically the temperature corresponding to the pressure at which the steam is condensed.

Self-cleaning valves of the sliding type are used. These are brass-lined and not liable to choke. The device feeds direct from the main or other source, discharging a continuous stream of are used in operating this trap and the



DUPLEX STEAM TRAP AND BOILER FEEDER.

water to the boiler. No levers or weights whole arrangement is located entirely on the exterior of the boiler where all parts are easily accessible.

When one tank is filling the other is emptying, the difference in weight of water in the drums operating the system.

The American Duplex Steam Trap Co. of Detroit, Mich., are the makers of this appliance.

DEVELOPMENT OF SHELL MAKING OPPORTUNITIES

THE certainty of a prolonged struggle in Europe has practically eliminated all uncertainty regarding developments in Canada's shell industry, and the net result is that we are now on the eve of embarking on the manufacture of types of shells in quantity, size and weight that not only easily surpass our present accomplishment, but call for equipment, methods, devices, attachments, and operative skill more diversified and more highly specialized than has yet been our privilege or opportunity.

The abnormal demand for machine tools and the myriad accessories incidental thereto shows little, if any, abatement so far as the manufacture of 3.3 shrapnel and 3.3 and 4.5 high explosive shells is concerned. In spite of this, and the fact that the placing of orders for these specialties will be continued without intermission and more or less indefinitely, contracts are being let for not only larger type shells, but for quantities of them that may easily rival the prolific production output of the above-mentioned small size projectiles.

Our editor has just returned from Ottawa, where he was privileged to meet Messrs. W. L. Hichens and R. H. Brand, who recently arrived from England to assume expert representation of the British Minister of Munitions on our Shell Committee.

Advantage was taken of the opportunity while in Ottawa to discuss a few features of the munitions situation in Canada and Great Britain at the present time, and relative to the easily unparalleled conditions that must necessarily be faced by both countries on conclusion of the war. The matter of ordnance manufacture in Canada also came under review.

Although but a few days in Canada, Messrs. Hichens and Brand had got well into harness, and, while the former was more or less a stranger in our midst, it was early apparent in the course of conversation that Mr. Brand was neither a stranger in the geographical sense of the word, nor in a business sense. Considering, however, the importance of the mission of the two gentlemen, it was by no means surprising that a widespread intimacy of men and things Canadian revealed itself.

Appreciation of the shell production of our metal-working plants, large and small, was expressed. Labor conditions were also touched upon, the employment of female labor on an extensive scale by munitions firms in Britain being referred to as the only solution there for the shortage of male labor, so far as maintenance and continuity of output was concerned.

Regarding the position of factories both here and in Great Britain when peace is declared, there was a tendency evident to presuppose a possibly brief but trying period during which the readjustments to peace conditions were being made. It was, however, anticipated that a gradual slowing down of munitions production would be operative through the better part of the succeeding twelve months, and that in the case of the specially-built and equipped "National" factories in Great Britain, these would be promptly closed down.

In the matter of the establishment of a Canadian ordnance factory, the consensus of opinion favored same, it being believed that, despite the lapse of time necessary to construct, equip and bring to the production stage such a plant, the venture would be worth while from the present war point of view, and would be an asset of considerable value to us against future war possibilities.

The addition to the personnel of Canada's Shell Committee of W. L. Hichens and R. H. Brand gives unmistakable proof of whole-hearted intention on the part of Britain's Munitions of War Minister to not only follow up the achievement of the Shell Committee formed by our Minister of Militia, but to strengthen, develop and broaden the scope by enlarging the opportunity of that body, and through it make our metal working plants more patriotically and commercially effective.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, Que., Nov. 8, 1915.—The general industrial situation still shows an improving tendency. While the bulk of the business is largely due to the filling of contracts for munitions and war supplies, considerable activity is being shown in other spheres of industrial enterprise.

Several plants, closely connected with shell-making in and around Montreal, are contemplating building additions to their present factories, or erecting new plants entirely to meet the requirements of the newly-placed orders. It is understood that the Canada Cement Company have commenced operations on a plant which, when completed, will be fully equipped with the necessary machinery for the production of 9.2 high explosive shells.

The successful harvesting of an unprecedented crop will go a long way to stimulate trade conditions in Canada. The transportation of the crop is expected to tax to the limit existing facilities and equipment, both on land and water.

Pig Iron

Reports from many sources show conditions steadily improving in the market for pig iron. For some time there was apparent the possibility of a shortage in the supply, due to the heavy demand for steel bars and billets. Production has, however, been well maintained, the pace set by the unprecedented output requirements of the steel mills notwithstanding. While advances fail to be noted in the quotations of foreign markets, local prices remain steady. Increased demand in the near future, due to the requirements of shell manufacturers, for the production of larger shells may cause a further advance and tend to create a scarcity.

If the production of pig iron becomes in excess of the quantity consumed, no serious inconvenience will be caused.

Steel

The exceptional situation in the iron and steel trade has a tendency to put the general markets somewhat out of balance. No definite prices can be obtained on many steel products, as many of the mills have withdrawn quotations. In numerous instances it is not a question of price, but of output, as the mills are full up with orders that will keep them busy at full capacity for a period of six months to a year or more. The advent of further orders for 3.3 and 4.5 shells and the placing of contracts for the larger high explosive shells will, of course, make the situation still more acute.

Purchasers of finished steel are having great difficulty in securing early delivery, and in some cases it is only the largest buyers that are getting any reasonable satisfaction on their manufacturing needs for 1916. Some concerns may find their future output seriously curtailed for lack of raw material.

Machine Tools and Supplies

Machine tool builders are having added responsibility placed upon them by the inquiries for equipment for the production of 5-in., 6-in., 8-in. and 9.2-in shells. No definite information is available as to the firms receiving orders for these munitions, but it is learned that several of the largest plants throughout the Eastern provinces have signed contracts for shell orders amounting to anywhere from $5,000,000 to $25,000,000. With the completion of the placing of these contracts and further orders for the smaller shells, the demand for tools is bound to tax the resources of machine tool makers to the utmost. The equipment necessary for the larger size shells will require very heavy machinery and facilities for handling will require careful consideration on the part of the tool builder and the shell manufacturer.

The 9.2-in. and 8-in. shells, and even the 6-in. shells, will necessarily require different equipment than that being used for the smaller and lighter projectiles. Convenient and economic methods must be adopted for handling the heavy shells in and out of the different machines and transferring them from opeeration to operation. Chain blocks, air hoists and monorails or transfer trucks will be required, and means of holding the shells and driving them while being turned will call for special thought and consideration. Inquiries have been received by one dealer for 35 large projectile lathes for the manufacture of 9.2-in. shells.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Messrs. S. Ruperti and Alexsieff, care Military Atache, Russian Embassy, Washington, D.C.

Metals

The general trend of the metal markets is to advance, and while quotations remain unchanged locally, there is a possibility of slight advances in some lines before the close of the present week. Lead will very likely be stronger. New York quotes the following advances:—Spelter, .75 cents; lead, .15 cents; tin, 2.32 cents, and antimony, 1.25 cents per pound.

Copper

Slight improvement is shown in the copper market, but owing to the comparatively poor showing of last month, producers are still in a position to supply the demand without noticeable advance in prices. Requirements of copper for shell orders now being placed may have some effect towards increasing prices.

Tin

While activity in the foreign markets appears brisk, the local situation is little changed from the previous week, and quotations are holding firm. An advance of 2.32 cents per lb. is shown on the New York market, due to the apparent scarcity of supply. Local dealers are quoting 38c per pound.

Spelter

A decline in the price of spelter is looked for in the near future. Producers are gradually increasing the supply over that of the demand, and prospects are that quotations on spelter will be lower than at present. Foreign demand has created an advance in the United States, but there is little to indicate what the ultimate condition of the market will be. The price is steady at 18 cents per lb.

Lead

Quotations on lead remain firm, and the situation is unchanged. However, local dealers expect an advance before the coming week. Present price, 6½ cents a lb.

Antimony

The market is quiet, but quotations remain firm, present price being 35 cents per lb.

Old Material

Business is quiet with dealers in old material. Inquiries for heavy melting steel and turnings have fallen off considerably. Prices remain unchanged,

with the exception of tea lead, which shows an advance of 25 cents per 100 lbs,. and scrap zinc; which has risen to $11.50 per 100 lbs.

Toronto, Ont., Nov. 9.—The industrial situation continues favorable and there is an increase of confidence for the future in business circles. In addition to heavy increases in exports the Dominion revenue is steadily growing. The customs returns for October were about four million dollars more than for the corresponding month of 1914, while for the first seven months of the present fiscal year the revenues were seven millions more than for the corresponding period of last year. The high ocean freight rates at present prevailing are a serious handicap to ordinary trade other than war business. The rates which are very much higher than at normal times, add considerably to the cost of the product and so have a tendency to restrict business.

Developments in the shell industry are being followed with the greatest interest; this is to be expected, considering the large amount of money involved. Contracts for the 6-in., 8-in. and 9.2-in. shells are being allotted gradually, and it is pretty well understood who are the recipients, although the amounts and values have not been given out officially. A large number of tenders for shells and shell parts have been submitted and their consideration requires considerable time and attention. The reorganization of the Shell Committee will probably not take place until the awarding of the various contracts has been completed. Sir Frederick Donaldson has left for England, where he will report to the War Office as to conditions in Canada and the feasibility of establishing ordnance works here.

Steel Market

The most important development in the steel market this week and one which indicates the trend of business is the withdrawal of prices on steel bars. The mills have taken this action on account of the unsettled condition of the market due to the heavy demand for steel and the difficulty in promising delivery. The mills will until further notice quote on application only for prompt acceptance. Canadian steel companies have advanced steel bars 10c. to $2.45 per 100 lbs., which price is really nominal. Iron bars are unchanged at $2.35. Pittsburgh bars for Canadian consumption are quoted nominally at 1.50c, but higher prices are more general. The steel market is very active and the demand for steel for munitions is steadily increasing. The placing of orders for the large-calibre shells will mean a considerable increase in tonnage, and will tax the capacity of the mills. This business will be additional to the requirements for the 18-pdr. shells, which are still being produced in large quantities. The steel trade is in an exceedingly prosperous condition and the present activity will no doubt be a permanent benefit to the industry.

Prices of electric weld coil chain have been reduced, but in all probability will only be effective a short time. With a higher tendency on all steel products, chain cannot help but be effected. Proof coil chain, fire welded, is unchanged but an advance is looked for in the near future. Seamless boiler tubes are very firm at last week's advance and may go still higher. Prices of boiler plates have been readjusted in an upward direction. Galvanized sheets are strong, some brands having been advanced. The tendency is decidedly in an upward direction on account of the high prices of spelter, acid and black sheets. There is only a fair demand for galvanized sheets in Canada, although in the States there is a large volume of export business. Bessemer black sheets No. 28 gauge are being quoted at 2.10c to 2.20c; open hearth; No. 28, 2.20c to 2.24c, and blue annealed No. 10 at 1.70c to 1.80c, Pittsburgh. "Premier" galvanized sheets are now being quoted at $5.20 per 100 lb. Toronto.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

The high-speed tool steel situation may fairly be said to be acute. The scarcity, especially under present conditions, is very serious and is causing considerable anxiety to makers of munitions. Although prices are advancing all the time, these ranging from $2.50 to $3.50 per lb., the makers are unable to promise either a definite delivery date or the amount specified. Stocks in Canada are very low and supplies are difficult to obtain from Sheffield, England, on account of the restrictions placed on exports of tool steel by the British Government because of the enormous demand and the necessity of conserving supplies. The heavy demand in the States also makes it exceedingly difficult to obtain supplies from the mills in that country.

The extraordinary demand in the States for steel, particularly for munitions, continues and the mills are overwhelmed with orders. The output is expanding rapidly and prices are steadily advancing. For domestic delivery all makers are quoting bars at 1.50c Pittsburgh, but export business is being booked at considerably higher figures. The heavy demand for billets continues and prices are still advancing. Bessemer billets are now being quoted at $26, open-hearth billets at $28, and forging billets range from $35 to $45 f.o.b. Pittsburgh.

Pig Iron

There is an increased demand for low-phosphorus pig iron and there appears to be some scarcity of this grade. It is reported that Canadian buyers are unable to satisfy their requirements, one interest being in the market for several thousand tons monthly. Foundry grades are in better demand, but the tonnage is comparatively light.

Machine Tools

Although it is understood that no contracts for the large shells have been signed up, a number of firms who are practically certain of getting some of the business are making preparations to this end. Enquiries have been sent out for heavy lathes, but few orders have actually been placed, although considerable activity is expected very shortly. The situation is interesting to local dealers, and also to the builders of suitable tools.

Supplies

The demand for machine shop supplies continues very active, and prices in some lines have advanced. An all-round advance in cotton and wool waste has been announced ranging from ¼c to 1c per pound according to quality, etc. The long expected advance in leather belting has materialized, the new discounts being 40 and 10 per cent. for extra heavy single and double, and 50 per cent. for standard quality. Prices of high-speed cutters are higher, and the list has been revised with extras added. Prices on high-speed twist drills are withdrawn and quotations made only for prompt acceptance. Benzine has advanced again, and is now quoted at 25½c per gallon in barrels. Gasoline is 3c higher and is quoted at 23c per gallon. There is practically no change in prices of linseed oil or turpentine, although the latter is subject to considerable fluctuation and ranges from 76c to 82c per gallon. Plumbers' oakum is a little higher, and is quoted at $4.50 per 100 lb.

Old Metals

The metal for scrap iron and steel is weaker, Canadian mills having covered their requirements meantime. No. 1 wrought iron and heavy melting steel are both lower, having dropped 50c a ton. Machinery cast iron is stronger and has advanced 50c per ton. The market

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Niagara Falls, Ont.—W. P. Gonder is in the market for turning machinery to cost $1,000.

Woodstock, Ont.—W. Baird & Son will build a machine shop to cost $4,000.

London, Ont.—The Empire Brass Co. will build an addition to their plant, to cost $1,300.

Montreal, Que.—The Canadian Tube & Iron Co. is building a machine shop on St. Patrick street.

Niagara Falls, Ont.—J. E. Gardner is in the market for a 20 h.p. engine and boiler to operate a sawmill.

Montreal, Que.—A fire at the Canadian Steel Foundries plant on St. Patrick street did about $1,500 damage on Nov. 2.

Owen Sound, Ont.—The Canadian Malleable Iron Co. will equip its plant for the manufacture of 60-lb. high-explosive shells.

Owen Sound, Ont.—The Owen Sound Iron Works Co. will shortly install machinery in its plant to manufacture high-explosive shells.

Mount Brydges, Ont.—R. H. Bellamy, Box 134, will purchase material for the factory to be erected here for the Crow Automobile Co.

Eustis, Que.—The Eustis Mining Co. will extend their plant at a cost of $100,000. Loomis & Dakin Co., Montreal, are the contractors.

Victoria, B.C.—The Victoria Chemical Co. will commence shortly on the erection of an addition to its plant for the manufacture of war material.

Leamington, Ont.—The town council have decided to call for tenders for two 110 h.p. boilers for the waterworks. A new boiler house will be built.

Chatham, Ont.—J. D. Dort of Flint, Mich., is associated with Robert Gray of this city in a proposition to establish a factory here for building motor cars.

Toronto, Ont.—It is announced that the Canadian Tygard Engine, Ltd., has purchased the old Ontario House, 942 Kingston road, for a factory, where aeroplane and submarine engines may be manufactured.

Sherbrooke, Que. — The Canadian Ingersoll Rand Co. will build a new machine shop to cost $50,000. Anglins, Ltd., Montreal, are the general contractors.

Vancouver, B. C.—An Eastern firm with a rolling mill costing from $120,000 to $160,000, is looking for a location at the coast, according to City Industrial Commissioner Davison.

Renfrew, Ont.—The O'Brien Munitions, Ltd., are building a smokeless powder plant of a capacity of 35,000 pounds per day. The plant will be opened about the first of the year.

Collingwood, Ont. — The Imperial Steel and Wire Co. is reported to have contracted with the British War Office for a supply of munitions and special articles used in trench warfare, the contract price being close to $5,000,000.

Chatham, Ont.—A deal has been closed whereby the American Well Works Co., of Aurora, Ill., will purchase the old Defiance Iron Works plant in Chatham. The plant was turned over to the new owners for $12,000. They will manufacture waterworks equipment.

Toronto, Ont.—The Canadian Tygard Engine, Ltd., has concluded the purchase of a tract of land at the corner of Kingston road and Lawlor avenue, East Toronto. The present buildings are to be utilized as a factory to fill orders until other buildings can be added.

Electrical

Stratford, Ont.—The Hydro Commission may install more transformers as the existing units are carrying a capacity load.

Kingston, Ont.—B. R. Newton, of Arden, situated about 50 miles from here, has water power capable of developing 2,000 h.p. which it is suggested should be taken over by the city and a hydro electric system installed.

Owen Sound, Ont.—The high tension work at the hydro-electric sub-station here is almost finished, and the current from the Eugenia Falls power plant could be turned on in Owen Sound if necessary. The wires which bring the power from Eugenia into Owen Sound at 22,000 volts have all been connected with the transformers which step it down to 2,300 volts.

Niagara, Falls, Ont.—The ratepayers on Nov. 3, at a special election passed a by-law approving a contract with the Hydro-Electric Commission of Ontario. The by-law was carried by a majority of 48. Another by-law appropriating $14,000 for machinery for the municipal electric light plant was carried by a majority of two. The Hydro contract calls for a minimum of 2,000 horse-power at $11.50 per horse-power, with an additional $1 per horse-power for transmission, and the term is 30 years.

General Industrial

London, Ont.—H. T. Reason contemplates the erection of a factory for the manufacture of paper boxes.

Kingston, Ont.—The City Council may buy a combination motor-driven pump, chemical and hose truck.

Peterborough, Ont.—Fire damaged the plant and stock of the Canadian Chicle Co. on Nov. 1, to extent of $6,000.

Oshawa, Ont.—The council will appoint a town engineer and waterworks superintendent. Thos. Morris is town clerk.

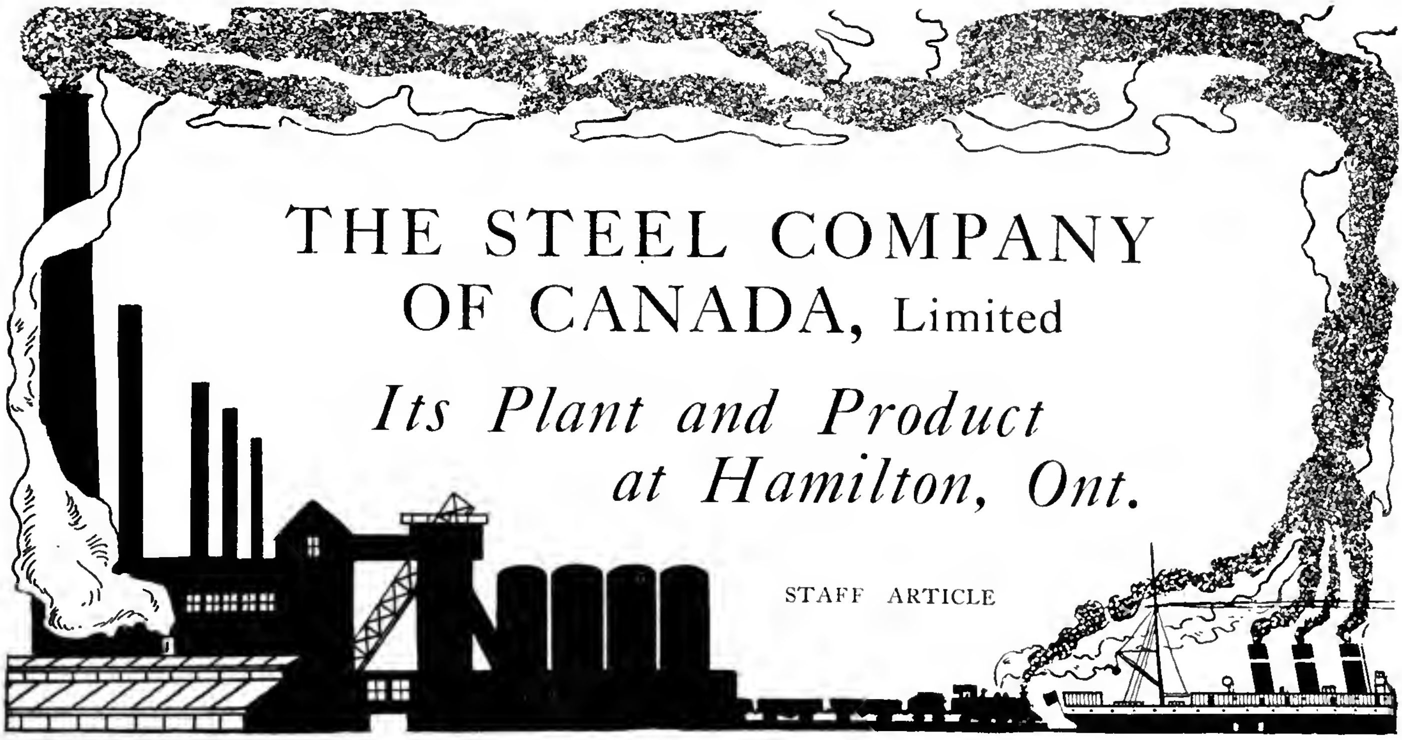
Paris, Ont.—The Paris Wincey Mills Co. will build a factory to cost $30,000. P. H. Secord & Sons, Brantford, are the contractors.

Prescott, Ont.—The Newell Mfg. Co. of Ogdensburg, N.Y., manufacturers of hardware, propose establishing a plant here. A by-law will be submitted to the ratepayers on Nov. 15.

Montreal, Que.—The Canadian Consolidated Rubber Co., Notre Dame Street, are building an extension to their factory to cost $3,000. G. M. Martin & Co. are the general contractors.

Wingham, Ont.—A representative of an American Safe Manufacturing Co. was in town last week looking through the old chair factory with a view to buying. He was greatly impressed with the town.

Windsor, Ont.—The representative of a large New England firm was in Windsor recently seeking a location for a branch plant. The company is anxious to find a building with 15,000 to 20,000 square feet of floor space, preferring rented quarters for the present.



THE STEEL COMPANY OF CANADA, Limited

Its Plant and Product at Hamilton, Ont.

STAFF ARTICLE

From the ore mines of Mesabi to the fighting front in France is a long way to go, but not long enough to prevent a steady flow of shells and other munitions of war. The help which Canada is giving to the Empire, grows in volume and variety as it progresses Eastward and the valued assistance being rendered by establishments such as the one described in this article is convincing evidence of Canada's present power and future potentiality.

THE entrance of Canada into the ranks of munitions producing nations was one of the unexpected events of a war, in which the unexpected has been more than once prominent. A year ago, when hostilities had been in progress for several months, there were few, if any, indeed, who foresaw the extent to which this country's resources would be relied upon for providing not only ammunition, but army stores of all descriptions in enormous quantities. Possessing an area of 3,817,000 square miles, equal to more than one-quarter of the land possessions of the Empire, with natural resources more varied and extensive than any other colony, and geographical location and political environment of the most favorable nature, Canada would have failed in her duty as a loyal colony had she exerted herself one whit less strenuously than she has done during the past year. Circumstances point to intensification and continuation of such efforts till the British Empire once more asserts itself as the chief factor in the world's peace, and in the attainment of such a state of affairs Canada will be looked to for increased help and support until the much desired consummation of events is attained.

The building of ordnance in the near future along with impending developments in munitions manufacture will tend more and more towards the consolidation of the Dominion as a self-contained and fully developed unit, and increase to a desirable extent the effective help so necessary in the terrible struggle for liberty and justice.

The Genesis of a Shell

While the successful production of guns will form the completion of Canada's military development, the demand for munitions has been most urgent, and so far the efforts of all parties have been so concentrated on actual production that few of us have realized that every step, every operation, every substance that enters into a finished shell, and last, but not least, the men and the guns to use them; in fact, each and every phase in the life of a shell from the ore mine to the battlefield is now in existence in this country.

The successful production of a modern artillery projectile is dependent on a degree of scientific knowledge, mechanical ability, and complexity of operations, of which the casual observer has only the faintest idea, and in devoting its efforts to the manufacture of munitions The Steel Company of Canada affords a splendid instance of that promptness, thoroughness and wholeheartedness which has been so characteristic of our manufacturers.

Immediately it became apparent that the company's services would be needed, preparations for new, and alterations to operating plant and equipment were begun and carried out with such promptness and alacrity that in a very short time, shells were being produced at a highly creditable rate, and during the months which the plant has been engaged on this work the company has earned a lasting reputation as a producer of material for this purpose of the very highest order. In considering this performance one must remember that the metal is made from the ore, the forging is made from the metal, and the finished shell produced from the forging all under the one management. The life story of a shell as observed at the company's various plants is fascinating, instructive and highly stimulative of that industrial patriotism which is so characteristic of Canada's present efforts.

Mining the Iron Ore

Situated in the Mesabi range of hills in the northern part of the State of Minnesota, close to the Canadian border, and 800 miles from Hamilton, Ont., as the crow flies, are vast deposits of iron ore. From this locality, known as the Lake Superior district, about 40,000,000 tons of hematite iron ore are shipped annually to blast fur-

naces which yield more than three-quarters of the pig iron production on the North American continent. This red or brown hematite is one of the richest forms of iron ore, containing in some cases as much as 68 per cent. of iron, and in appearance resembles soft brownish earth. The deposits of the Mesabi range of hills lie near the surface, and are mined by means of immense steam shovels or excavators, such as are used for digging foundations, canals, railway cuttings, etc. These deposits are particularly adapted for handling by machinery, and the mining, transportation, and unloading of this material have resulted in the perfection of mechanical appliances of wonderful capacity and efficiency.

Lake Transportation

Ore boats carrying 10,000 or 12,000 tons of ore in one cargo, convey the ore to its destination. These boats are loaded from immense bins, into which the cars from the mines are emptied, the bins being elevated above the level of the boats, so that by means of ore chutes leading into each hatchway, the ore is rapidly conveyed by gravity into the hold of the vessel. In a few hours the ship has received its cargo and is ready to start on its long journey down the chain of inland lakes to its destination, where unloading of the boats is accomplished almost as rapidly as the loading.

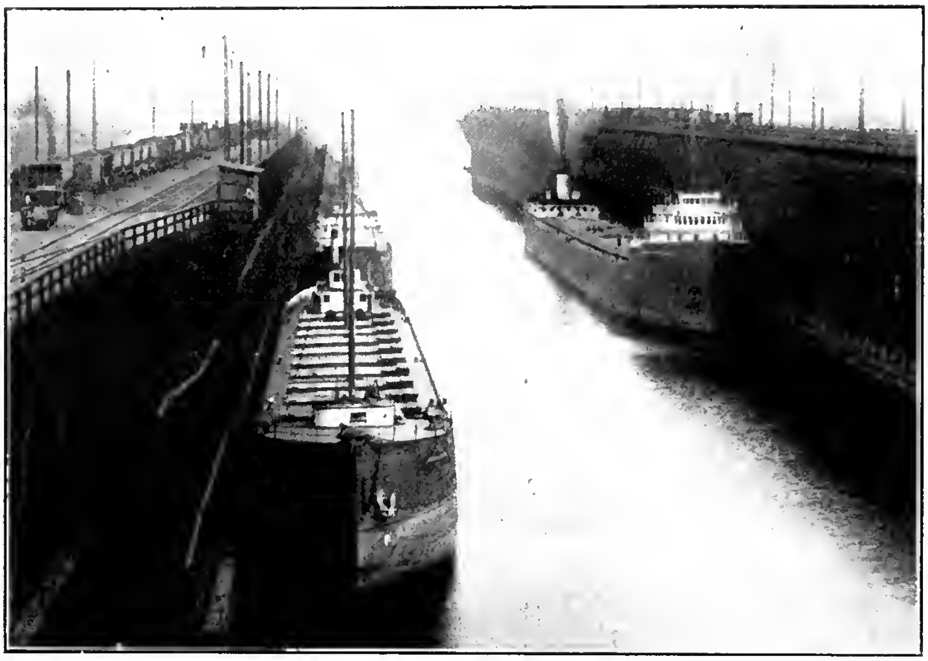


Photo. LOADING ORE BOATS AT MESABA ORE DOCK, DULUTH. Gallagher, Duluth.

The Production of Pig Iron

The plant of The Steel Company of Canada is complete in every detail, and is considered by many authorities to be of most modern design and construction. Here, in an extent of several acres, and in the course of a few hours may be seen steel in every stage of production from iron ore, barely distinguishable from common earth to the shrapnel and high-explosive shell, wanting only the addition of the explosive charge and propellant to make it ready for actual use in battle.

A short explanation of the reasons for and nature of the various processes through which the metal passes, may render clearer a description of the plant.

The first step in the manufacture of steel from iron ore is to separate the iron from the various substances associated with it in that form. This is accomplished by smelting the ore in a blast furnace with fuel and flux, whereby much of the impurities is removed, and a cast iron, commonly known as pig iron, is obtained. The pig iron thus produced is still an impure grade of

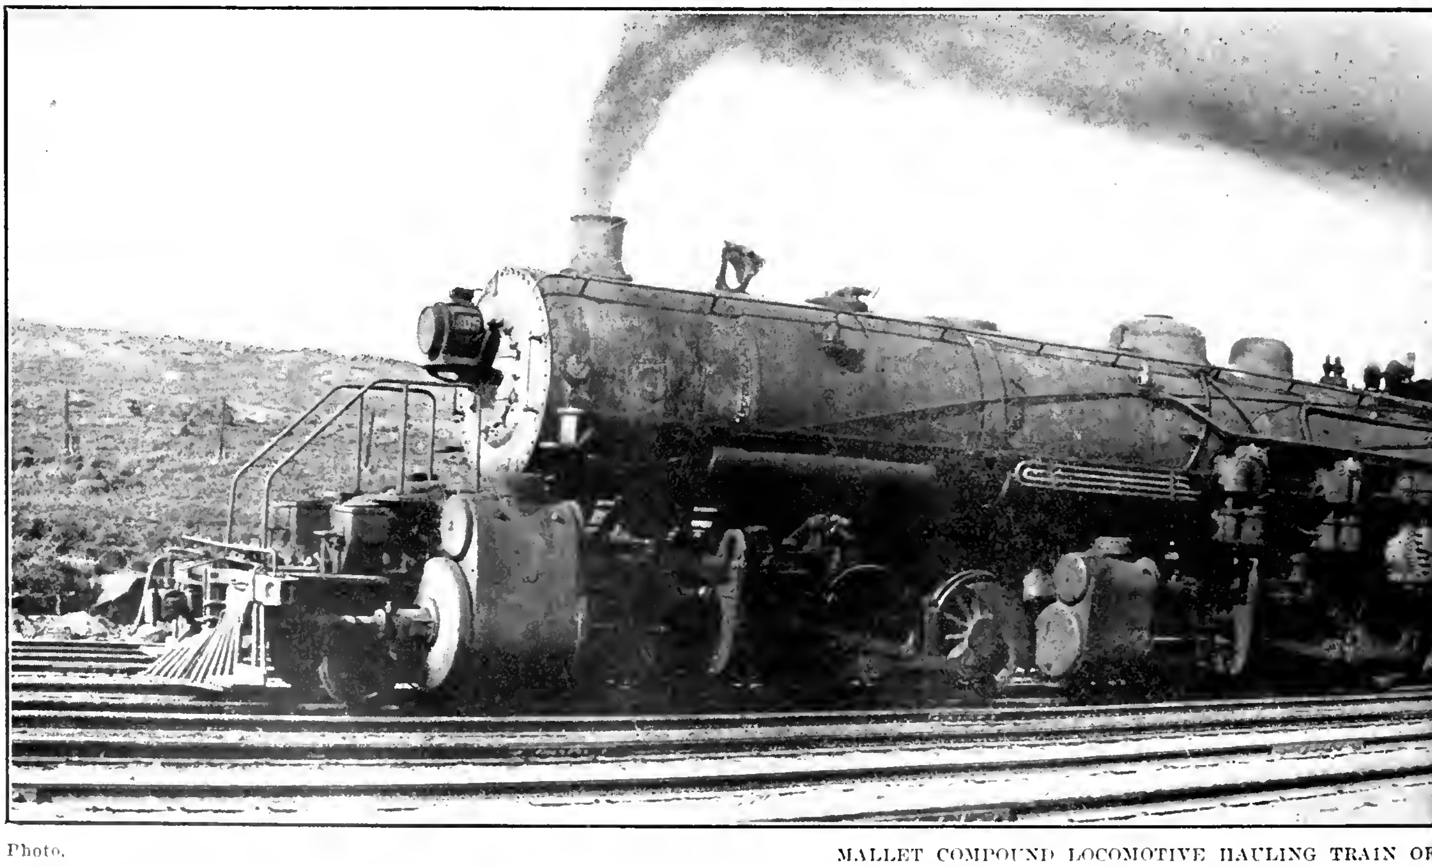

Photo. MALLET COMPOUND LOCOMOTIVE HAULING TRAIN OF

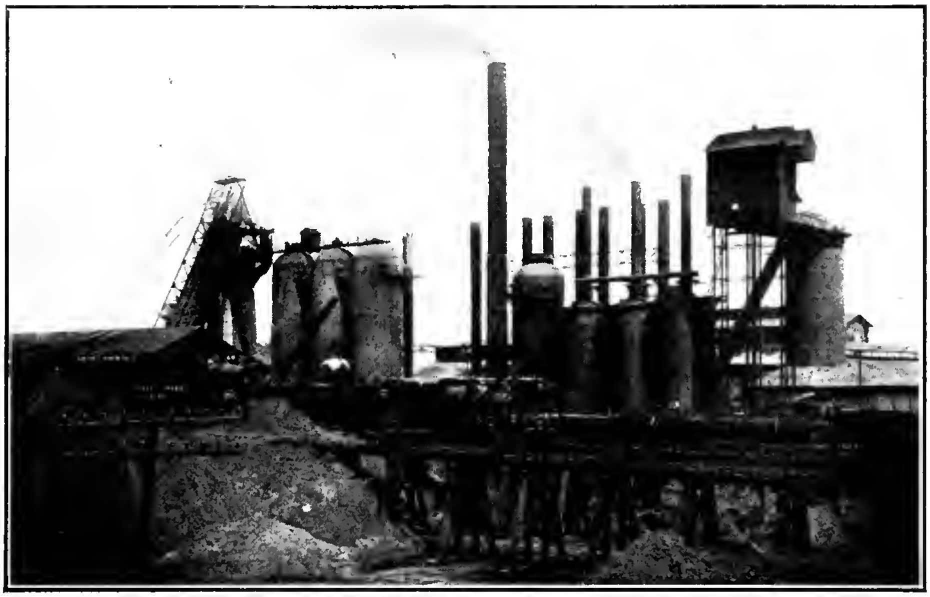
iron, containing roughly 1.00 per cent. silicon, 0.1 per cent. sulphur, 1.50 per cent. phosphorus, 1.50 per cent. manganese, 3.50 per cent. carbon. A steel suitable for projectile manufacture would have a composition approximately thus: .15 silicon, 0.03 per cent. sulphur, 0.05 per cent. phosphorus, 0.70 per cent. manganese, 0.50 per cent. carbon. In order to obtain metal of this composition it is necessary to remove nearly all of the various impurities from the pig iron, and then add the necessary proportions of such ingredients as are desired.

This constitutes steel-making proper, and may be accomplished by various processes, all of which are similar in general principles, though differing widely in certain features which have important bearing on the finished produce.

After the desired chemical composition has been obtained, the steel is subjected to various mechanical treatments terminating with its appearance in the shape of the now familiar shell forging.

The Blast Furnace

Returning now to the blast furnace—the iron ore arrives in hopper bottom cars, which are run out on elevated tracks and dumped in huge storage piles in close proximity to the blast furnace. Limestone and coke, which are necessary materials in steel-making, are similarly stored.



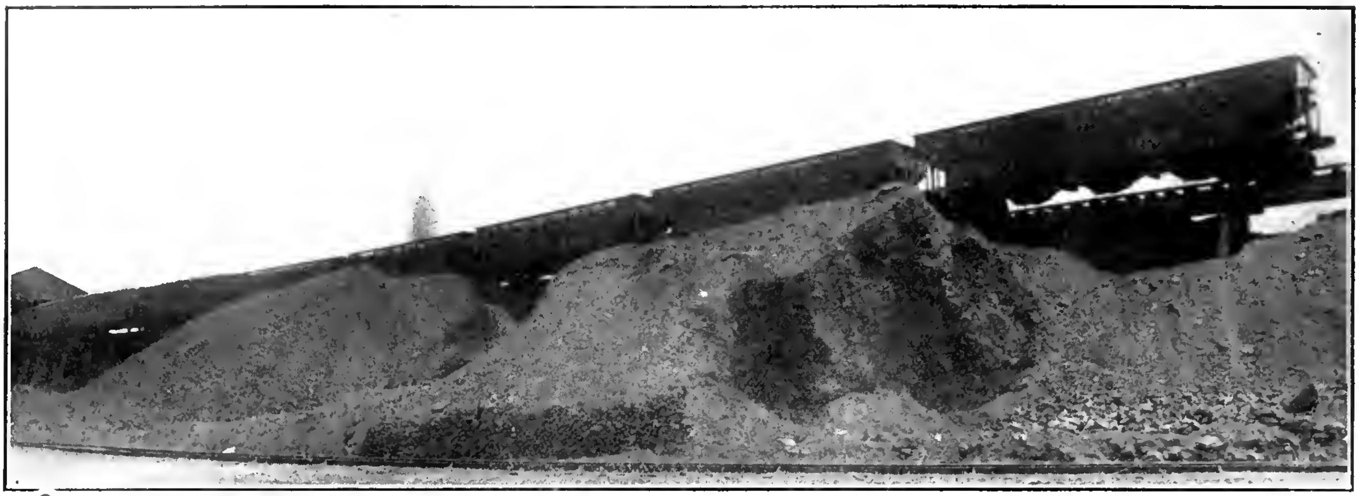
BLAST FURNACE PLANT OF THE STEEL COMPANY OF CANADA, LTD., HAMILTON, ONT.

A sectional view of the blast furnace with skip hoist and charging bins is shown on page 465.

The charging bins are situated well above ground level, the discharge spouts being so arranged that the necessary amounts of ore, coke and limestone may be fed into a travelling dump car provided with scales, and running on a track below the bins. The car empties its load of material into the skip, two of which are used, one descending to be filled when the other ascends with the charge for the furnace. When the loaded skip nears the top of the hoist tracks, projections on the ends of the rear axle engage with suitable curved guide rails, and tip the skip over so that its contents are discharged into the hopper on top of the furnace. This hopper is of double construction, being fitted with two bells or cones A and B. Bell B is held against the bottom of the upper hopper by a counterweight, and is opened by hydraulic gear, thus allowing the charge to fall into the main hopper I, which in turn is closed by bell A. When hopper I has been charged with the proper quantities of ore, limestone and coke, bell A is opened, while bell B is kept tightly

LOADED CARS FROM ORE MINES TO LAKE SUPERIOR — Gallagher, Duluth.

closed. The contents are now precipitated into the furnace, while the gas is prevented from escaping by bell B and going to waste as formerly, thus giving rise to the long flame which some years ago was such a prominent feature of blast furnace plants.



STORAGE PILES OF IRON ORE AWAITING TREATMENT IN BLAST FURNACE.

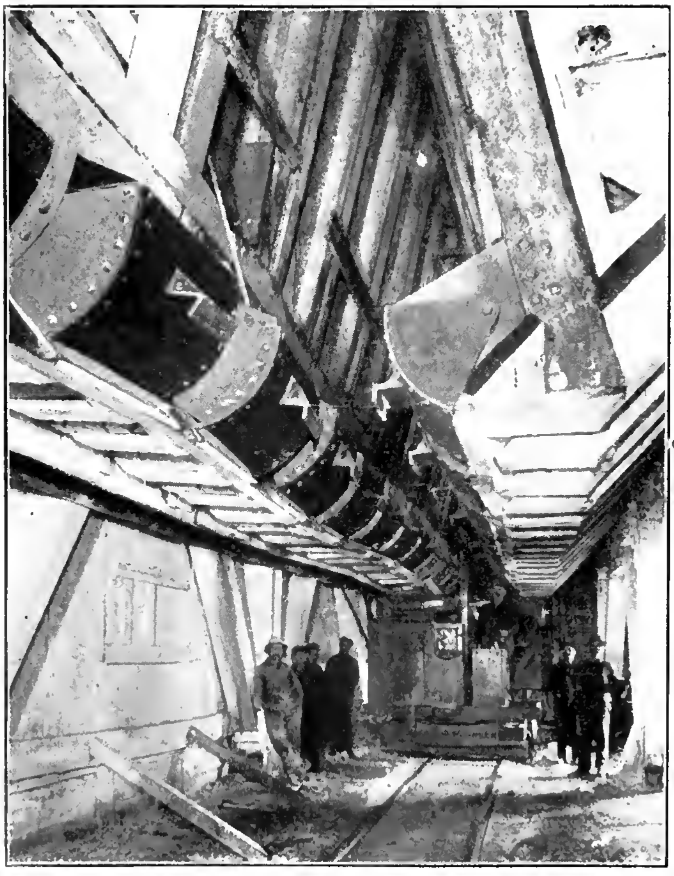
Design

As will be observed from the drawing, a blast furnace consists of a vertical brick-lined shaft, the internal shape being of a special outline, which has assumed its present form and proportions as the result of experience and scientific investigation. The lining of the furnace consists of acid (silicious) fire-brick, into the outer surface of which are built numerous water pipes for cooling purposes. These are easily seen in the photograph on page 466.

Encircling the lower part of the furnace is the blast pipe L, which supplies air to the furnace through the tuyeres N. The tuyeres, 12 in number, extend through the lining, the openings or "notches" as well as the tuyeres being cooled by water circulating through special pipes and hollow shields.

The hearth is the lower portion of the furnace, about 8 ft. in height, with vertical sides. Above that for a distance of 12 ft. is a portion of gradually increasing diameter, known as the bosh. From the top of the bosh, which is the largest diameter of the furnace, the walls close in gradually, forming the stack, which extends upwards to the throat where the charging hopper is located.

About three feet below the level of the tuyeres a hole is provided, known as the "cinder notch" or "monkey." This is protected by a water-cooled casting, and is closed by means of an iron plug. The purpose of this hole is to draw off the cinder and prevent it reaching the level of the tuyeres. On a level with the bottom of the crucible, on the front side of the furnace, is the iron tap-hole through which the liquid metal is drawn off from the furnace. This is simply a large hole in the brick work, which is stopped with clay balls. In tapping the furnace, these balls are broken up with a bar, and in order to stop the hole again a mud gun is employed, which shoots the balls of clay into the hole. This gun is seen lying at the base of the furnace in photograph on page 466.



ELECTRICALLY DRIVEN CHARGING CAR WHICH WEIGHS THE ORE, COKE, ETC., AS DELIVERED BY OVERHEAD CHUTES FROM CHARGING BINS.

Blowing Engines

The air which is necessary to operate the furnace is supplied at a pressure of from 15 to 30 lb. per sq. in., according to furnace conditions. The blowing engines for supplying this air are of a type which is more or less peculiar to blast furnace plants, and one of these is shown in a photograph on page 465. They are what are known as disconnected compound, long cross-head blowing engines. The steam cylinders are 44 in. and 84 in. diameter by 60 in. stroke, and are placed above the blowing cylinders, which are located between the flywheels.

Before entering the furnaces the air is heated to a temperature of 900 to 1,250 deg. Fahr. by passing through the hot blast stoves. These stoves, of which there are three, are distinctive features in the appearance of blast furnace plants. They are upwards of 100 ft. high and 20 ft. in diameter.

The hot gas from the top of the blast furnace is conveyed through large pipes to the base of the stoves, where it is mixed with air and burned. The products of combustion pass upwards through the central passage and then downward through the surrounding space, which is constructed of suitably arranged fire-brick chambers, after which the gases escape through the chimney. After running for a certain period, the stove has absorbed a maximum amount of heat from the gases, and the process is then reversed. The air from the blowing engines is now re-

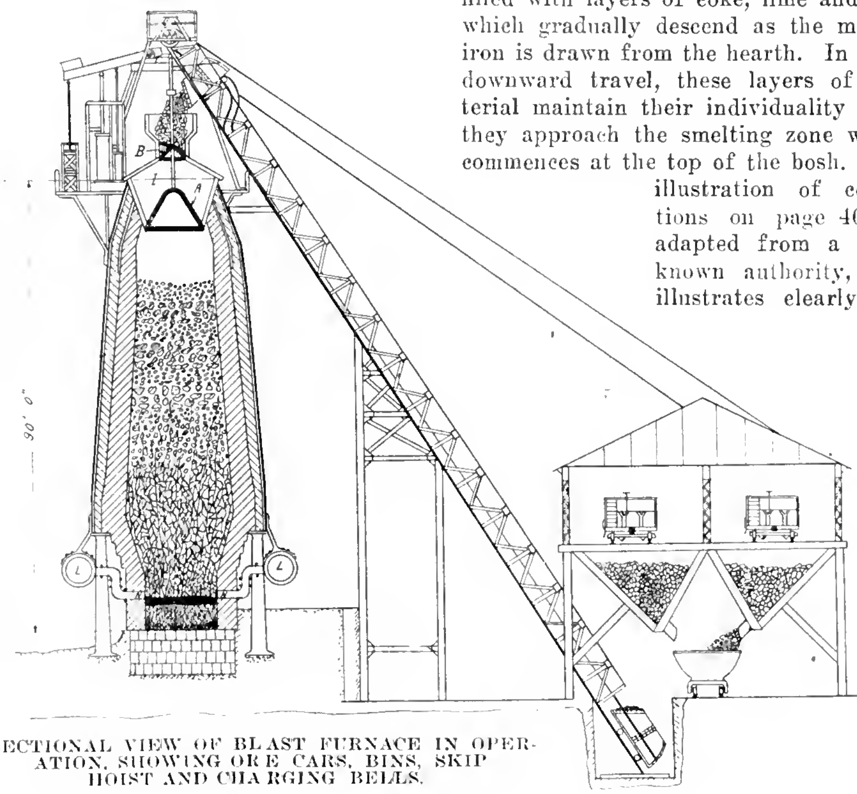
ceived through a valve at the base of the chimney, and, passing upwards through the hot fire-brick, is raised to a high temperature before passing out at the bottom of the central passage and thence to the tuyeres. When this reversal takes place, the hot gases from the furnace are switched into that stove, which was previously heating the air. While one stove is heating the air, the remaining stoves are being warmed up by the hot gases. In order to maintain a fairly regular temperature in the blast furnace, the stoves are changed over about once an hour.

Utilizing the Waste Gases

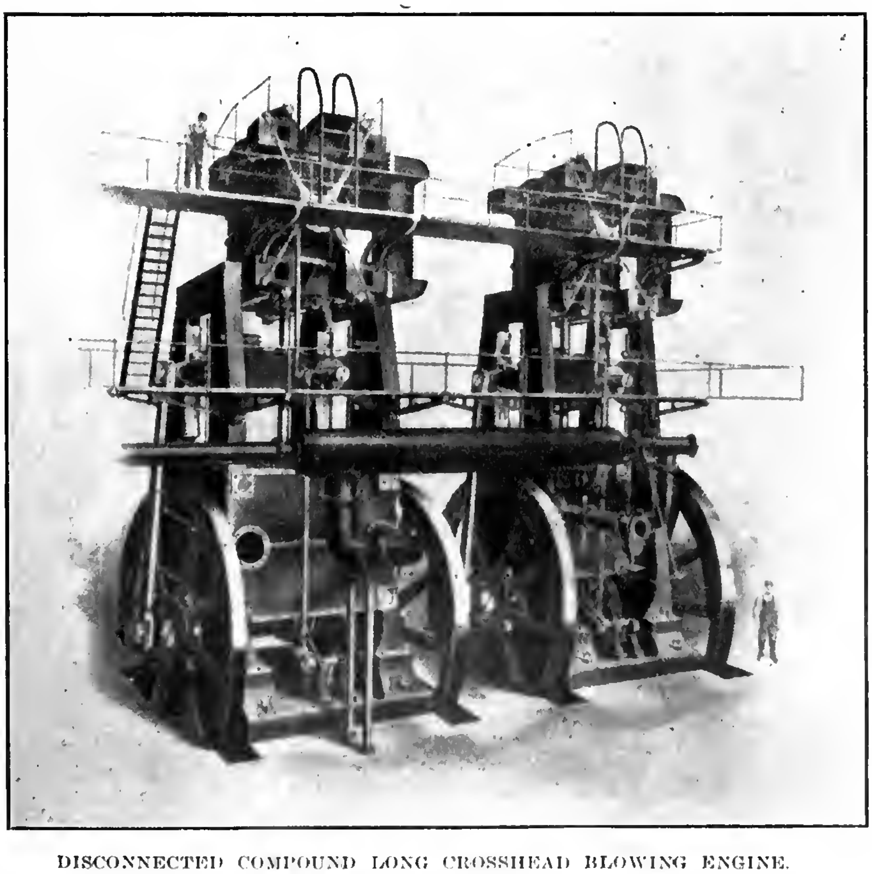
Only one-third of the waste gases from the blast furnace is necessary to keep the stoves hot, and the remaining two-thirds are available for use in various ways. In the case of this plant, the gas is burned under a battery of boilers, producing the steam required to operate the blowing engines and refrigerating plant which is required for drying the air before entering the stoves.

Undried air, if blown directly into the furnace, would carry with it water vapor equivalent to from 1 1/3 to 8 gallons per minute, according to the humidity of the air, materially cooling the smelting zone of the furnace. The process of drying the air by refrigeration was originated by James Gayley, a prominent American steel maker, and the saving in fuel and increased regularity of working due to the absence of moisture have resulted in its adoption by the leading plants in various countries.

The air-drying plant consists of three 150-ton compound steam-driven ammonia compressors, which supply the necessary refrigeration for cooling the brine which is circulated by three steam-driven flywheel type brine pumps.



SECTIONAL VIEW OF BLAST FURNACE IN OPERATION, SHOWING ORE CARS, BINS, SKIP HOIST AND CHARGING BELLS.



DISCONNECTED COMPOUND LONG CROSSHEAD BLOWING ENGINE.

Operation of the Blast Furnace

When in operation, the furnace is filled with layers of coke, lime and ore, which gradually descend as the molten iron is drawn from the hearth. In their downward travel, these layers of material maintain their individuality until they approach the smelting zone which commences at the top of the bosh. The illustration of conditions on page 466 is adapted from a well-known authority, and illustrates clearly the action of the various materials. The exact location of the smelting zone is dependent upon the volume and pressure of blast, size of furnace, character of slag made, etc., but will extend from the level of the tuyeres to a few feet above them, or about to the top of the bosh. It will require perhaps fifteen hours for the material to descend from the top of the furnace to the smelting zone. During this descent, it is upheld partly by the resistance of the uprushing column of hot gases, partly by its friction on the walls of the furnace, and partly by the loose column of coke which extends through the smelting zone and to the bottom of the furnace, and which alone resists melting in the intense heat of this zone. The oxygen of the air blast attacks all the coke in the smelting zone and as much of it below the level of the tuyeres as is not covered by accumulations of iron and slag in the hearth, producing a large volume of carbon monoxide gas (CO), and a temperature which may exceed 3,000 deg. Fahr. This CO along with the nitrogen of the blast passes up between the particles of solid material, which takes up the greater part of their heat. The CO also performs certain chemical reactions, and thus in both ways the rising column of gases prepares the charge for its final reduction in the smelting zone.

Smelting the Iron

When the charge has travelled about half-way down the furnace, the in-

creased temperature breaks up the limestone, and from this point down to the smelting zone the ore is gradually re-

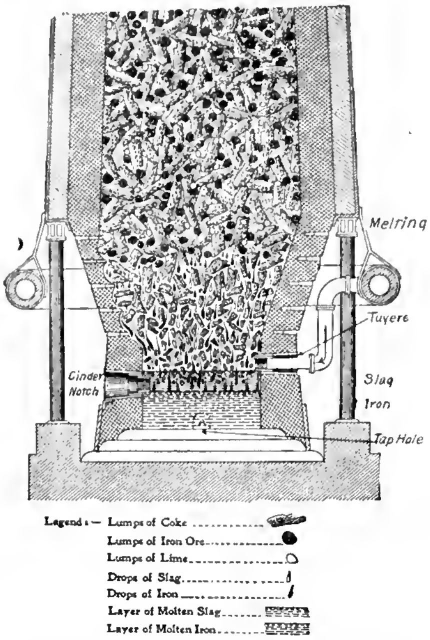


DIAGRAM SHOWING VARIOUS STAGES IN PROCESS OF SMELTING IRON ORE.
From Howe, "Iron, Steel and other Alloys."

duced to metallic iron. This spongy iron is impregnated with deposited carbon, which is absorbed in a similar manner to the process known as carbonizing. This reduces the melting point of the iron, and causes it to become liquid at a higher point above the tuyeres than it otherwise would.

On reaching the smelting zone, the iron melts and trickles quickly down over the columns of coke, from which it completes its saturation with carbon. At a corresponding point the lime unites with the coke ash and impurities in the iron ore, forming a fusible slag, which also trickles down and collects on the hearth. It is during this transit that the different impurities are reduced by the carbon, and the extent of this reduction determines the characteristics of the pig iron, for in this operation as in all smelting, reduced elements are dissolved by the metal, while those in the oxidized form are dissolved by the slag.

The slag is drawn off through the cinder notch four or five times, between each tapping of the furnace, which takes place about every six hours. This is run through channels in the sand floor to ladle cars at the side of the cast house, whence it is taken to the water front and dumped into the bay, making an ideal foundation for the reclaimed land which is being gradually brought into existence on the company's lake front.

Tapping the Furnace

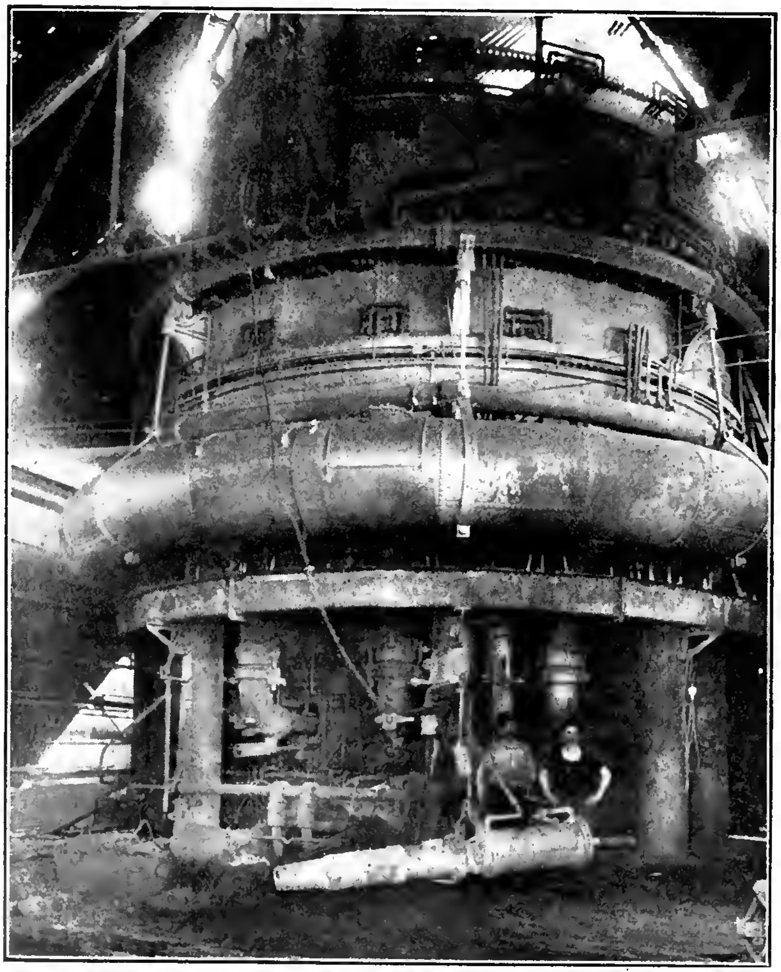
The scene in the cast house when the furnace is tapped is one which impresses even the most passive observers. The tap hole is opened by breaking up the clay balls which were forced into it, forming a solid plug. The molten iron flows underneath a skimmer, which deflects the floating slag into its own runner, while the iron flows into brick-lined ladles at the end of the cast house, which are immediately transferred to the open-hearth department and deposited in a large cylindrical vessel known as the mixer, where it is kept hot until it is time to charge it into the open-hearth furnace, where further changes in its composition are affected, which finally transform it into that indispensable metal—steel.

Manufacture of Steel

The physical properties possessed by iron as produced in the blast furnace are such as to render it unsuited for shells. The large proportion of carbon and other impurities present impart a brittleness and absence of ductility which are entirely absent when these substances are wholly or partially eliminated. This elimination or purification is performed by various processes, but the chemical action of oxidation is common to all.

The particular process of purification adopted by the Steel Company of Canada is that known as the basic open-hearth process, and differs sufficiently from other processes to demand a brief description. In all cases of purification, i.e., steel-making, the impurities are removed from the pig iron by means of oxidation—that is to say, the molten metal is subjected to the action of oxygen either in the form of air or iron oxide or both. The name of Bessemer naturally occurs to many people in connection with steel-making, and in the pro-

EXTERIOR VIEW OF BLAST FURNACE. SHOWING PIPES FOR CONVEYING WASTE GASES TO STOVES. DUST SEPARATOR IN FOREGROUND.

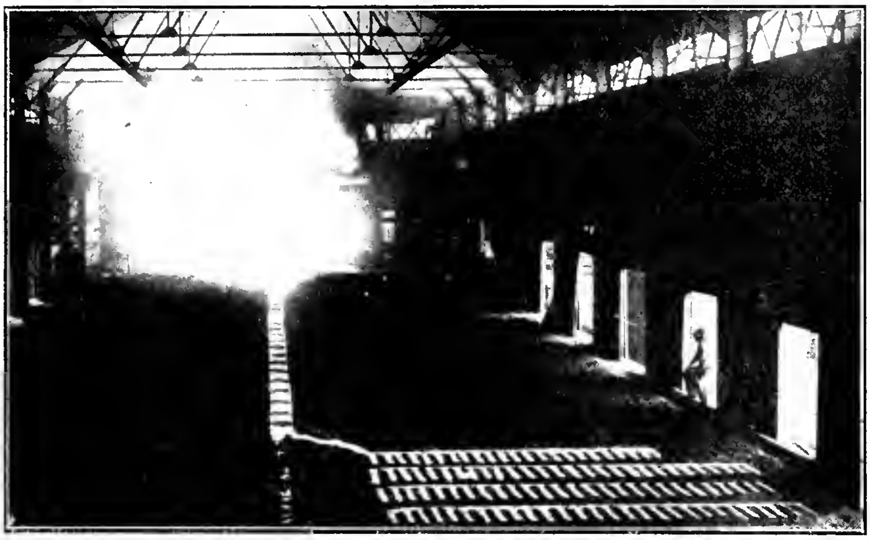


BASE OF STACK SHOWING LARGE BLAST PIPE SUPPLYING AIR TO THE TUYERES. STEAM OPERATED MUD GUN IN FOREGROUND USED FOR PLUGGING TAP HOLE BEHIND THE MUZZLE.

cess invented by the late Sir Henry Bessemer, air alone is used to remove the impurities from the molten iron.

Bessemer Process

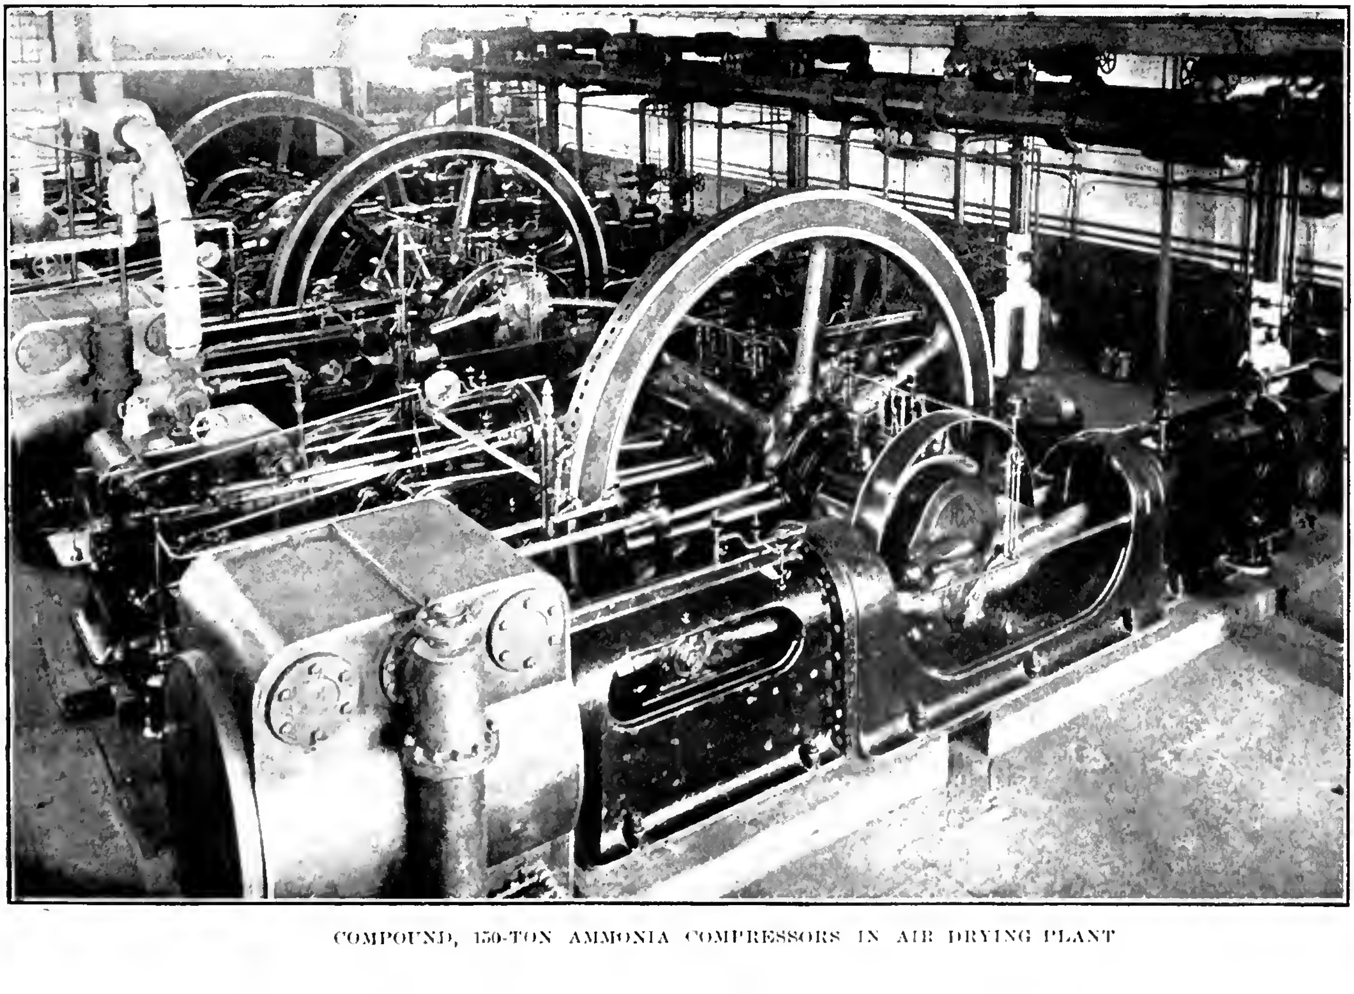
A large pear-shaped vessel known as a converter is lined with suitable protective material and provided with means whereby air can be forced upwards from the bottom with sufficient force to bubble through the molten metal. A converter, as the receptacle is termed, with a capacity of 15 tons, would require 30,000 cu. ft. of cold air per minute. The effect of such treatment on the iron impresses the lay mind chiefly by reason of its peculiar physical aspect, but no matter how wonderful its behaviour and appearance during this treatment, the resulting changes in the physical properties of the metal are little short of marvellous. A concise description of a "blow" or "heat" is given by Bradley Stoughton. "In about four minutes the silicon and manganese are all oxidized by the oxygen of the air and have formed a slag. The carbon then begins to oxidize to carbon monoxide, CO, and this boils up through the metal and pours out of the mouth of the vessel in a long brilliant flame. After another six minutes the flame shortens or 'drops' the operator knows that the carbon has been eliminated to the lowest practicable limit (say 0.04 per cent.), and the operation is stopped. So great has been the heat evolved by the oxidation of the impurities that the temperature is now higher than it was at the start, and we have a white-hot liquid mass of relatively pure metal. To this is added a carefully calculated amount of carbon to produce the desired degree of strength or hardness, or both; also about 1.0 per cent. of manganese and 0.15 per cent. of silicon. The manganese is added to remove from the bath the oxygen with which it has become charged during the operation, and which would render the steel unfit for use. The silicon is added to get rid of the gases which are contained in the bath. After adding these materials, or 'recarburing' as it is called, the metal is poured into ingots, which are allowed to solidify, and are then rolled, while hot, into the desired size and form."



CAST HOUSE, SHOWING THE MOLTEN IRON BEING RUN INTO MOULDS OR PIGS.

Basic Open-Hearth Process

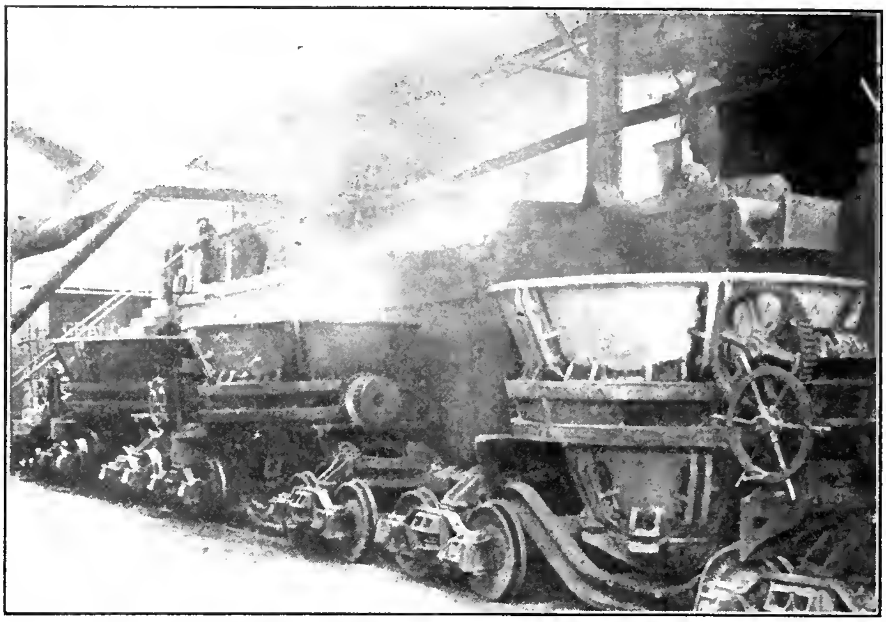
The open-hearth process in operation at this plant differs considerably from



COMPOUND, 150-TON AMMONIA COMPRESSORS IN AIR DRYING PLANT

the Bessemer process, and its use in preference to the other is due to a complexity of circumstances, such as nature of ores available, quality of product desired, demands of customers, etc. The basic open-hearth differs from the acid open-hearth in the nature of the lining and the composition of the slag produced, the effect of which is to aid greatly in the removal of phosphorus and sulphur, thus permitting the use of high phosphorus ores as distinguished from low phosphorus ores, which are necessary for both Bessemer and acid open-hearth practice.

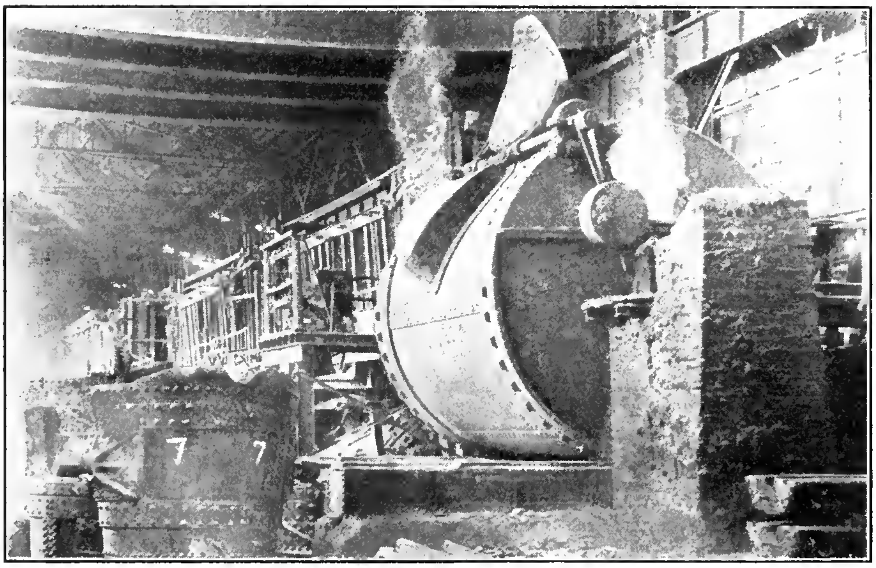
A sectional view of the furnace plant is given on page 469, while the accompanying views of the melting platform, charging machine, casting pit and ingot teeming give a good idea of the actual conditions under which the work of steel making is carried on.



RUNNING SLAG FROM THE BLAST FURNACE INTO LADLE-CARS.

Furnace Arrangement

The furnaces, which are in continuous operation, are of the stationary type, in which the metal is drawn off through a tap hole in the sides (see photo of casting pit). The melting platform or charging floor is on the other side of the furnaces and on the same level as the hearth. Two charging machines travel along this floor on rails, while directly in front of the furnaces is a standard gauge track on which trucks convey the scrap metal and limestone which are deposited in the furnaces through the various doors shown. Spanning the casting pit, which is situated on actual ground level, are two traveling cranes for handling the ladles in charging, teeming, etc. The mixer, which is at one end of the casting pit, is also served by these cranes.



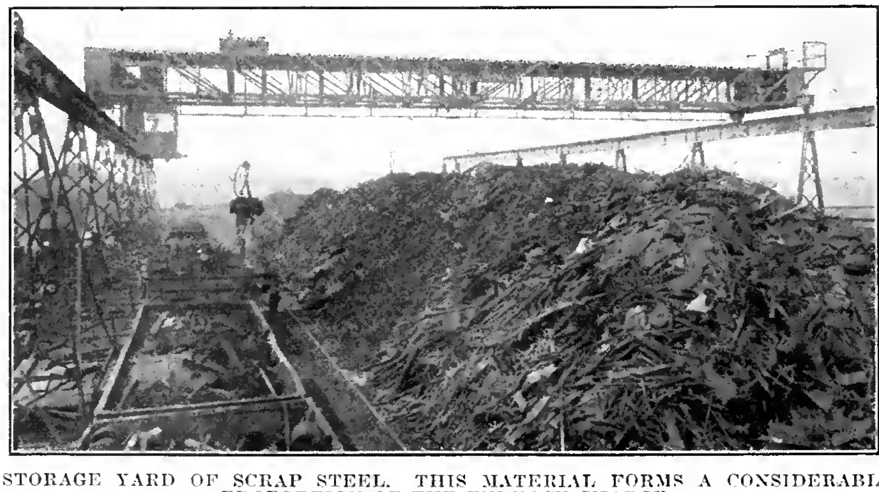
THE MIXER WHICH RECEIVES THE MOLTEN IRON TO PREPARE IT FOR TREATMENT IN OPEN-HEARTH FURNACE.

Situated on the opposite side of the charging floor and at a lower level are the gas producers, which supply the necessary fuel for the furnaces. Regenerators or preheating chambers are built beneath the charging floor, and perform a similar function to that of the hot blast stoves in connection with the blast furnace.

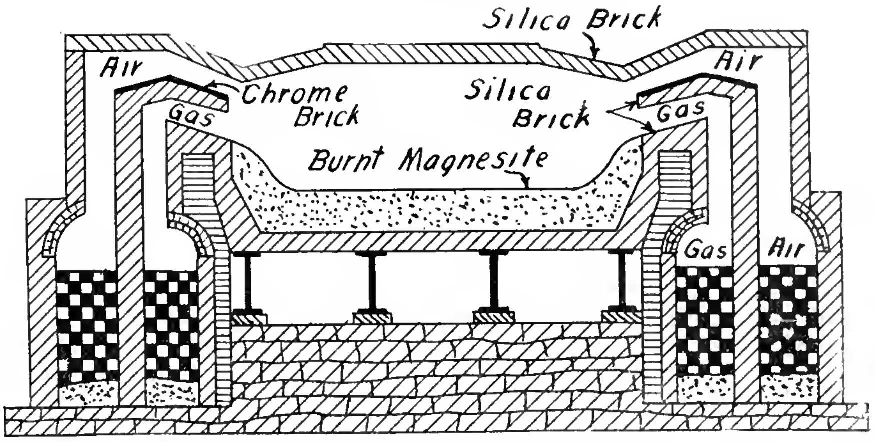
Construction of Furnaces

A longitudinal section of one of the furnaces is given on page 469, from which the principle of construction can be understood. The hearth in which the metal lies is formed of a shallow dish-like depression, which in the case of a 50-ton furnace is about 24 inches deep. The bottom is composed of a magnesite brick shell on which is built up a special lining of calcined magnesite with a small proportion of anhydrous tar, which acts as a binder. This magnesite and tar is deposited on the surface, where the tar is immediately incinerated, forming a strong frame work, which holds the magnesite securely in place. By means of successive layers this protective coating is built up to a thickness of 18 inches.

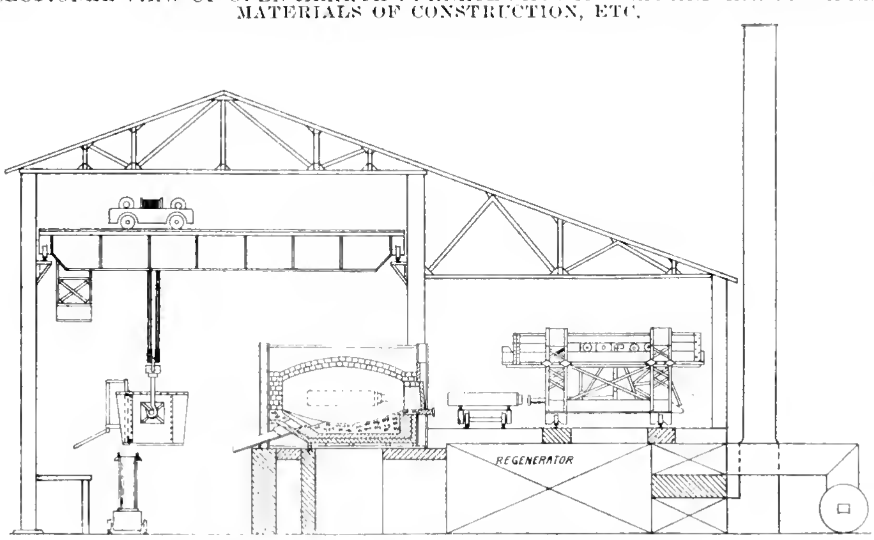
The fuel and air enter the furnace through separate ports at the same end of the furnace. Ports are provided at



STORAGE YARD OF SCRAP STEEL. THIS MATERIAL FORMS A CONSIDERABLE PROPORTION OF THE FURNACE CHARGE.



SECTIONAL VIEW OF OPEN-HEARTH FURNACE SHOWING GAS AND AIR PASSAGES, MATERIALS OF CONSTRUCTION, ETC.



SECTION OF OPEN-HEARTH FURNACE BUILDING.

both ends, however, so that each pair of ports alternately acts as exit for the products of combination, which are conveyed through the regenerators to the chimney flue. After a suitable lapse of time the ports are reversed, so that the incoming gas and air is heated by the regenerators which were previously being heated by the waste gases, the ports which formerly supplied the fuel and air now acting as exits and allowing the regenerators in their flues to be heated again.

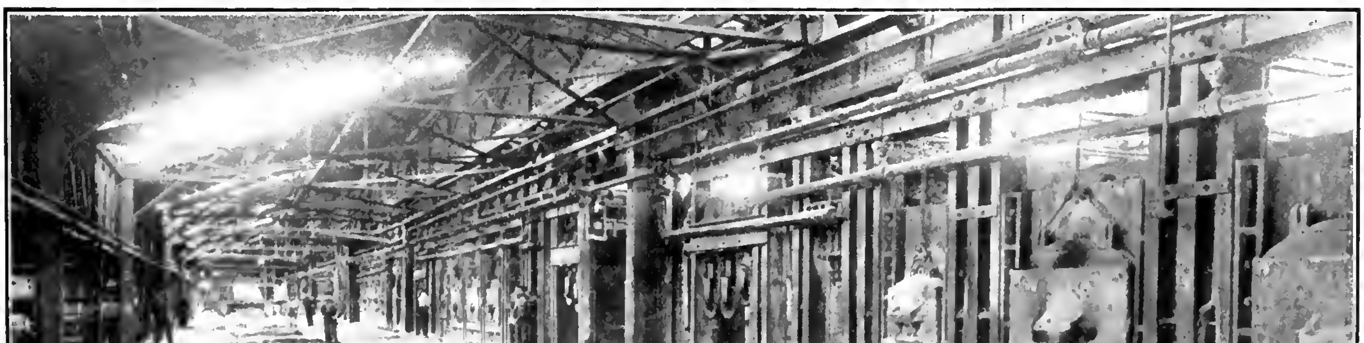
Charging the Furnace

In charging the furnace, the charging machine is placed opposite the furnace door. Between the machine and the door is a truck with a number of long buckets containing limestone. One end of each bucket is specially formed so that the arm of the machine is able to pick it up and carry it forward into the furnace and then revolve it, so that the contents are distributed equally over the bottom. Steel scrap and other cold metal is then added, and lastly, the molten iron from the blast furnace, which has been held over in the mixer till the furnace is ready to receive it. This molten iron is charged through a special door on the casting pit side of the furnace. The object in charging this last is to avoid damage to the furnace lining, which would result from dropping solid lumps of stone and metal into the liquid iron.

The charge melts down in about five hours or so. When this is complete, the melter takes a sample and continues to do so at stated intervals, until the laboratory tests show the desired composition. The charge is now run off through the tap hole, which was securely closed by forcing material into it from the inside of the furnace. As will be observed in the illustration of the casting pit, a gallery extends round the furnace close to the tap hole, and the hole is pierced by a man from this position. The metal pours out in a state of great fluidity, its appearance being like white hot water. After 35 or 40 tons are in the huge ladle, the surface ripples and waves, due to the pouring, continue to travel back and forth across the surface, and indicate in a most impressive manner the wonderful nature of the operations incidental to the production of steel.

The results of the various reactions which take place in the open-hearth furnace are these.

The molten lime absorbs the silicon, manganese and phosphorus with a proportion of sulphur, after which it floats on the surface of the metal and protects it from being oxidized by the furnace gases. The carbon content is brought down by introducing iron ore at a suitable time, the

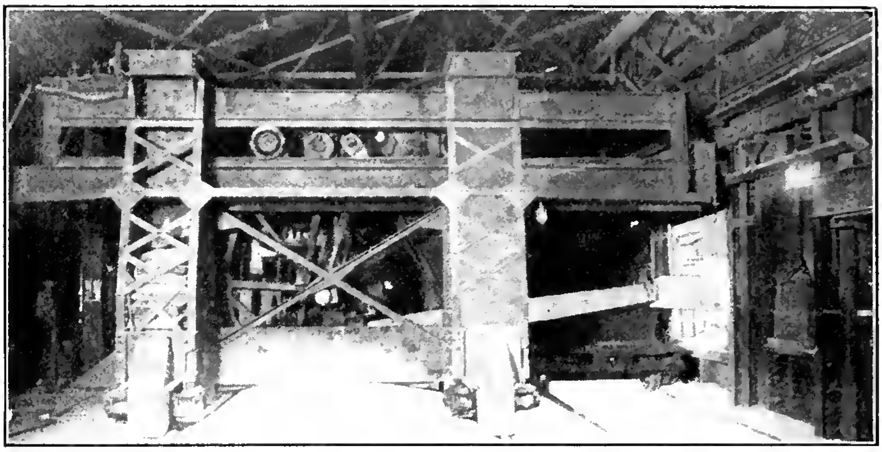


CHARGING FLOOR IN OPEN-HEARTH BUILDING. FURNACES ON RIGHT.

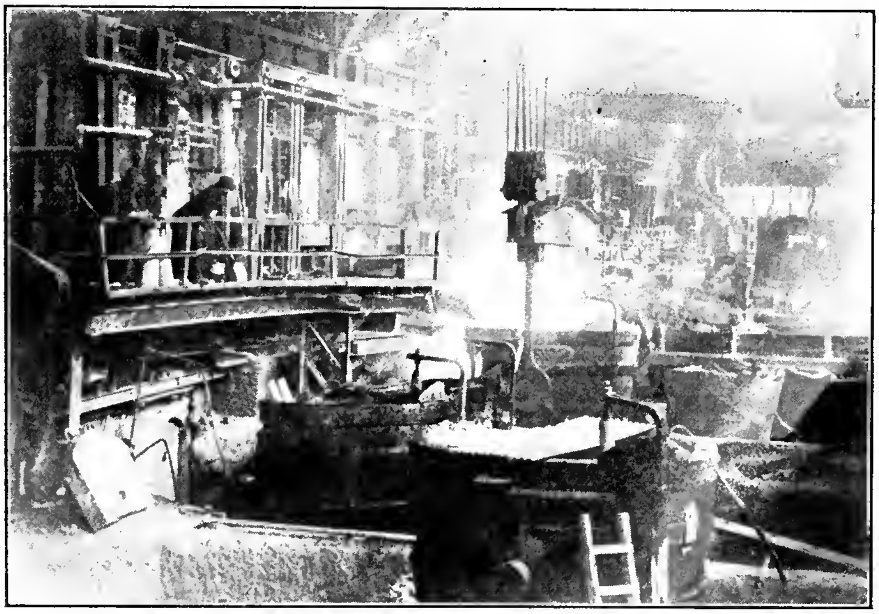
oxygen of which combines with the carbon, boiling off and escaping as gas.

While the metal is running off into the teeming ladle it is recarburized by adding to it the necessary quantity of ferro-manganese and charcoal or coke. These materials are prepared in suitable size, and at a given time during the filling of the ladle, two large paper bags containing the mixture are thrown in from the gallery. About half of the carbon content of the materials is absorbed by the steel, and if all calculations and operations have been correctly made and carried out, the steel has now a composition roughly as follows: Silicon, 0.15 per cent.; sulphur, 0.03 per cent.; phosphorus, 0.05 per cent.; manganese, 0.70 per cent.; carbon, 0.50 per cent.

deposits it in a section of the soaking pit, where it is maintained in an upright position at a steady temperature for about one hour. This treatment is necessary to allow the ingot to attain an even temperature throughout, and also to confine the pipe or segregation core to the centre.



CHARGING MACHINE DEPOSITING MATERIAL IN FURNACE.



CASTING PIT. RUNNING CHARGE FROM FURNACE INTO TEEMING LADLE

Each soaking pit furnace supplies heat to four holes, 5 ft. x 8 ft. 6 in., capable of holding eight ingots each, and served by a 10-ton soaking pit crane installed by the Morgan Engineering Co. These furnaces are fired by producer gas generated by four Morgan gas producers. They are provided with regenerating chambers similar to the open-hearth furnaces, suitable chambers and passages being provided for reversing the flow of the gases in order to utilize all of the heat. A photograph on page 471 gives a view of the top, showing the hydraulic cylinders which operate the doors. These doors are made of fire-brick tiles, supported in a suitable frame and run on wheels giving easy access to the various pits. The actual manufacture of the steel is now completed, as all subsequent operations are of a more

Teeming

The pouring of the molten steel into moulds is known as teeming. The teeming ladle is made of heavy sheet steel lined with fire-brick and provided with a stopper or plug which fits into a hole in the bottom. The stopper is controlled by a handle which allows the operator to control the flow of metal into the ingot moulds, the ladle being moved over each mould by the overhead crane from which it is suspended. These moulds are of very massive cast iron construction and rest on stools carried by the cars. After the ingot moulds are filled, the train of cars is taken to the rolling mill, by which time the metal is sufficiently solidified to allow the mould to be drawn off or stripped, as shown in photograph. This is done by a 75-ton Alliance crane, which has a pair of links which grip the mould under the lugs and pull it up clear of the ingot. Another crane immediately grips the ingot and

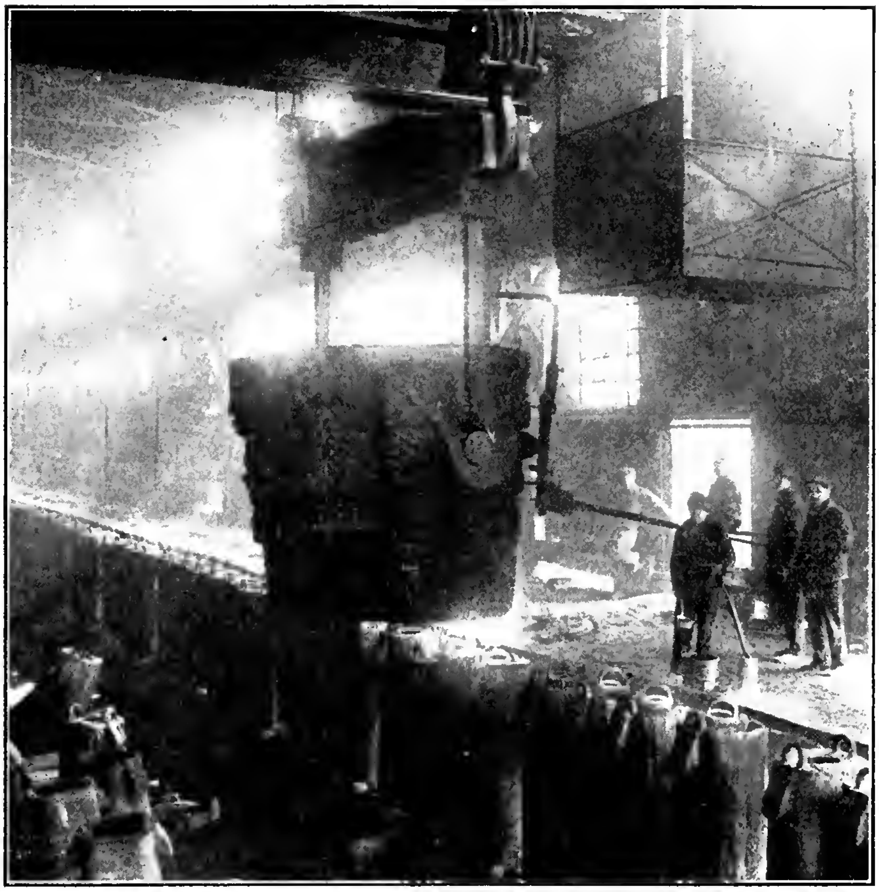
or less mechanical nature, and exercise no decisive influence on the chemical composition or quality of the steel.

The Mechanical Treatment of Steel

Steel which is cast, i.e., poured into moulds after being drawn from the furnace, is subject to certain defects, the prevention and removal of which can be accomplished by suitable means. Ingotism, piping and segregation are three of the defects liable to occur in steel. The former consists of the formation of excessively large crystals which form when molten steel is cooled too slowly, and also when it is not poured at the correct temperature. This crystalline structure when allowed to take place may persist throughout the entire ingot, whereas piping and segregation are more of a localized nature.



"TEEMING" THE MOLTEN STEEL INTO INGOT MOULDS.

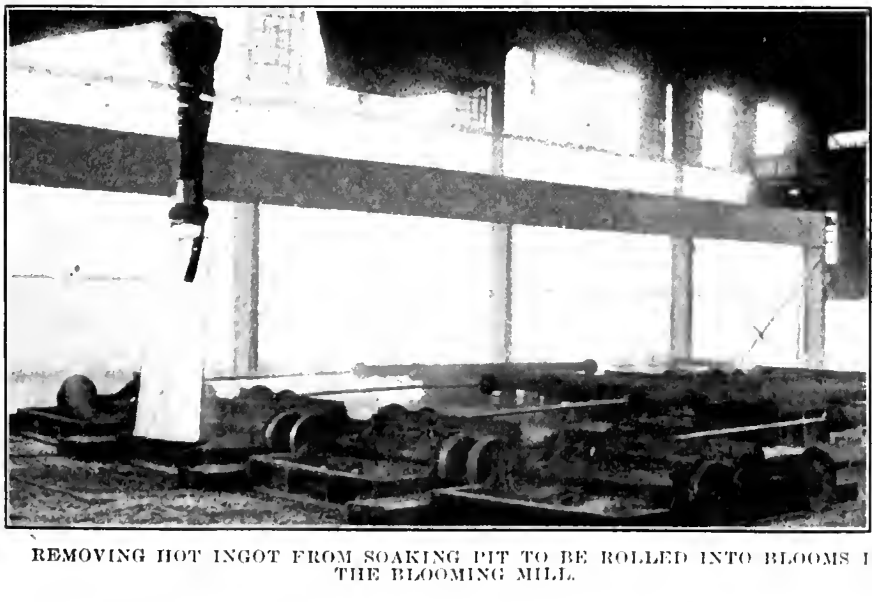
Piping, the term applied to the central porous core at the upper end of the ingot, is due to the shrinkage of the outer layers which induces an outward flow of the still liquid metal in the centre. This reduction in internal pressure also facilitates the evolution of contained gases which fill up the spaces left by the solidifying metal, resulting finally in the peculiar structure known as a "pipe."

Segregation is a partial separation of the various ingredients from the iron during solidification, due to the difference in fusibility of the various impurities and the iron itself. As the presence of some of the impurities lowers the melting point of the iron without increasing their own solubility, the result is that when the lower layers of steel solidify, a small portion of the impurities is rejected and passes upward into the still molten metal. This action proceeds upward through the ingot until when the topmost metal reaches the point of solidification, the percentage of impurities present is considerably greater than in the bulk of the ingot.

Segregation and piping cannot be entirely eliminated, but by suitable treatment and the use of deoxidizers, such as aluminum, etc., the trouble can be not only greatly reduced, but localized, so that the cropping of a comparatively small portion of the upper end of the ingot removes completely all possibility of harm from these causes. The progress made in this direction will be realized from the fact that although specifications for shell steel called for the discard of 40 per cent. of the ingot when operations were commenced, the thoroughness of manufacture and the resulting high quality of material have enabled this loss to be reduced below 15 per cent. with a large margin of safety.

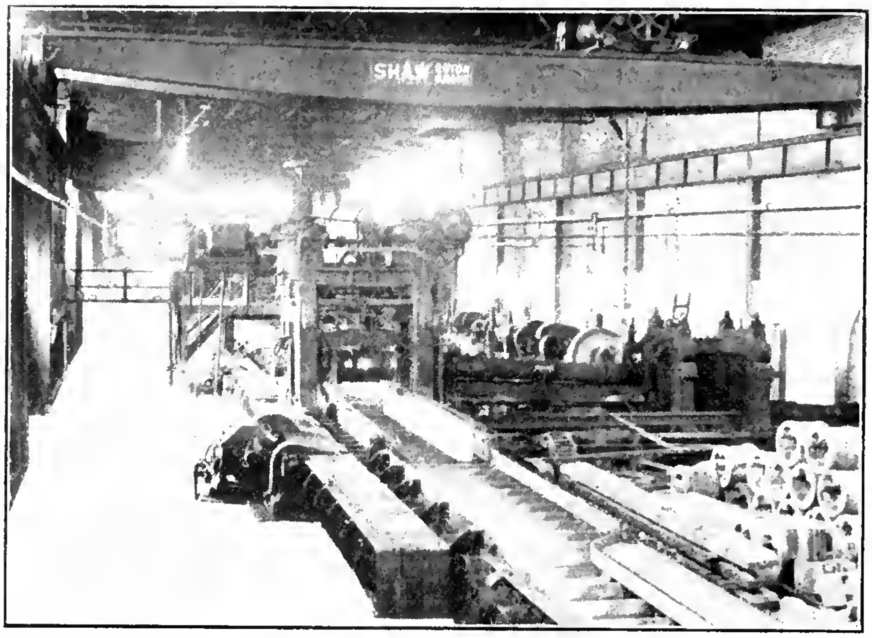
Rolling the Steel

Having now been in the soaking pit



REMOVING HOT INGOT FROM SOAKING PIT TO BE ROLLED INTO BLOOMS IN THE BLOOMING MILL.

STRIPPING THE MOULD FROM THE HOT INGOT.



ELECTRICALLY-DRIVEN REVERSING BLOOMING MILL.

long enough to attain the necessary condition as regards solidification and temperature, the ingot is withdrawn from the pit by the crane and deposited on the approach table of the blooming mill. The ingot, which is 15 in. x 17 in. x 7 ft. long, is passed back and forth between massive steel rollers, which while reducing its cross-sectional area, increases its length until, when reduced to about 6 inches square, the bloom, as it is now termed, is 50 ft. in length.

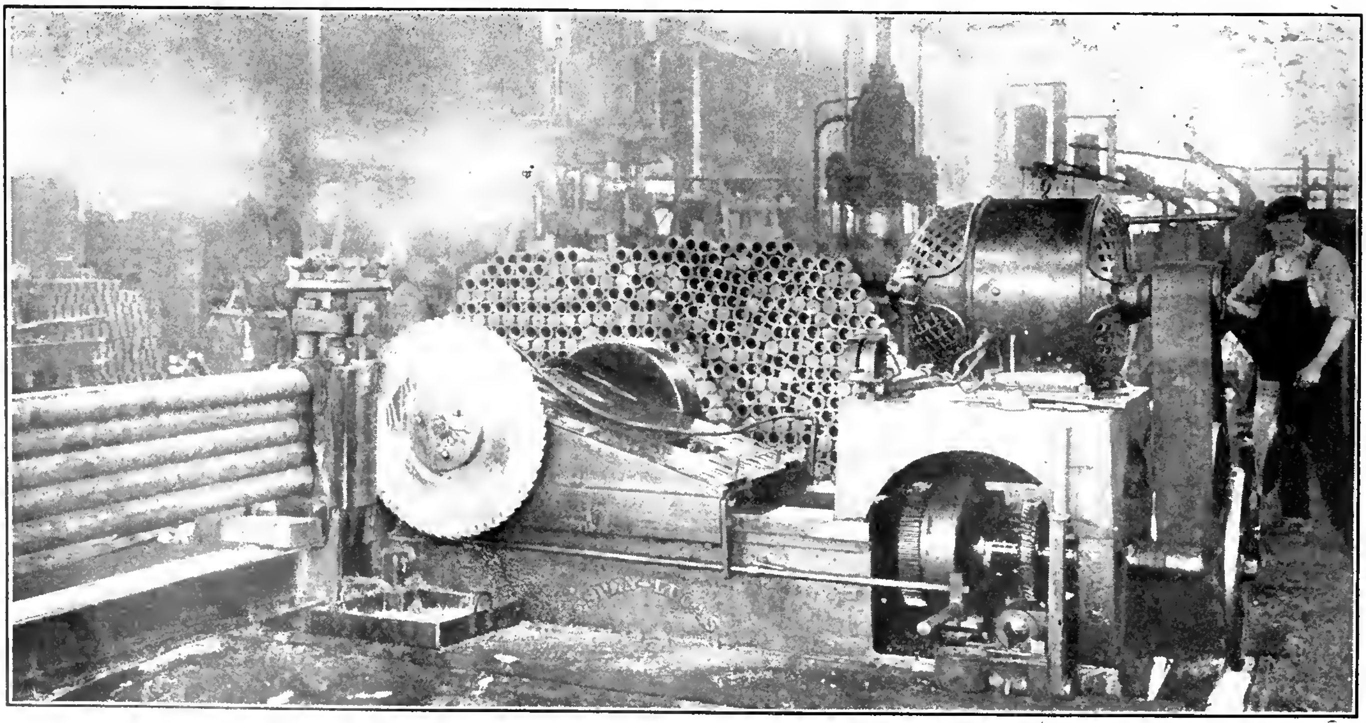
A photograph on this page shows a semi-finished bloom entering between the rollers of this mill, which is very complete in design and construction and along with its power plant is one of the best examples of modern steel working machinery on this continent.

The installation consists of a two-high 34-inch reversing motor-driven blooming mill designed by the Morgan Construction Company and built at the Lloyd-Booth plant of the United Engineering and Foundry Co., Pittsburgh, and is served by a Shaw 20-ton crane. The approach table in the immediate foreground is operated by a 30 horse-power direct-current motor, while the tables on either side of the mill are driven by 100-horse-power motors. The side guards for handling the bloom from one part of the rolls to another, are operated by hydraulic gear to the right of the tables. Here are also located the pinion housings. The lower pinion is directly coupled to the motor shaft, which passes through the wall into the power house; the other end of the pinion shaft is coupled to the lower roll of the mill.

The spindle or shaft which connects the upper pinion with the upper roll is provided at either end with a flexible coupling or wobbler, so that the spindle may assume an inclined position as the upper roller is raised or lowered to suit the thickness of metal passing between the rolls. The traveling crane is provided with special tackle to facilitate changing rolls and replacing pinions, etc., in case of accident. The entire operation of the mill is controlled from a platform or pulpit located above the table, affording a clear view of the rolls and the work.

After being reduced to the desired size, which is accomplished in 15 to 18 passes, the bloom is cut to suitable lengths in a 10 x 10-inch vertical bloom shear, which then go to the finishing mill, which reduces them still further to a round section of suitable diameter according to the size of shell to be made.

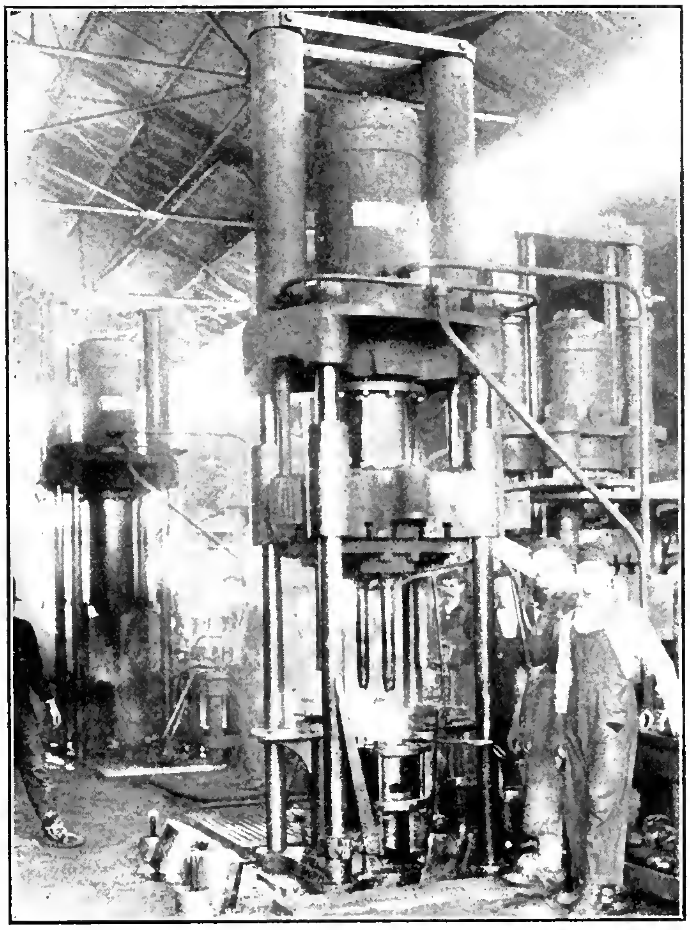
The blooming mill is driven by a 3,000 horse-power normal rating twin armature reversing motor, constructed by the Canadian Westinghouse Co., Hamilton, Ont., operated by electric power purchased from the Dominion Power & Transmission Co., which operates a 42,000 h.p. hydro-electric plant near St. Catharines, Ont., about 40 miles distant. The current, which is received at 44,000 volts, 66 2/3 cycles, is stepped down to 2,200 volts three-phase for the large motors and to 220 volts, two-phase, for several smaller motors and for lighting



ELECTRICALLY-DRIVEN SAW CUTTING FIVE BARS OF SHELL STEEL AT ONCE.

and all other purposes throughout the plant.

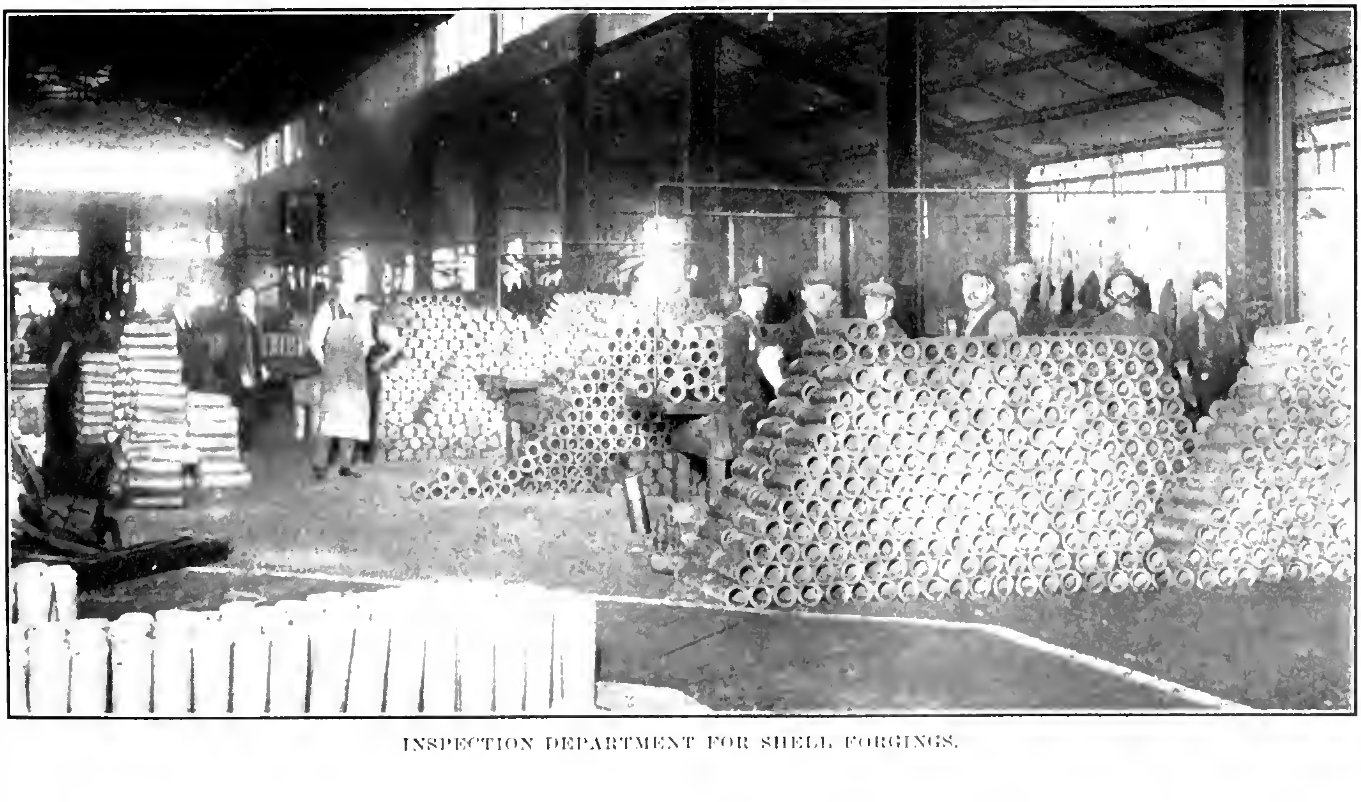
When breaking down ingots into blooms for the billet mill, the steel is given 18 passes through the rolls, but when breaking down for 6 x 6-inch blooms, the number of passes is reduced to 15. It is apparent, therefore, that the loads on the motor-generator set which supplies power to the reversing motor will vary rapidly over a wide range, the rate of change at times aggregating 4,000 to 5,000 horsepower per second during acceleration and approximately the same when braking. A load of this kind from the standpoint of power supply would be exceedingly undesirable and the cost of the current necessarily would be excessive. The twin armature reversing motor, while rated at 3,000 horse-power is, therefore, designed to carry a momentary peak load of 8,000 horse-power, receiving the necessary electrical energy through the medium of a motor-generator flywheel set consisting of one 1,800 horsepower alternating current, 2,200-volt, three-phase motor mounted on a common shaft with a 50-ton flywheel and two 1,200 kilowatt generators. This set is located in a power house on the other side of the wall from the blooming mill. Under light loads the fly-wheel has a speed of 500 r.p.m., while under the heaviest loads its speed does not fall below 400 revolutions per minute. The flywheel stores up energy during the period of light load and attains its maximum speed. When the heavy momentary loads comes on, the speed of the flywheel is allowed to drop, thus enabling it to deliver some of its stored-up energy in order to help the generators supply sufficient power to the reversing motor without making excessive demands on the external supply of electrical power.



VIEW OF SHRAPNEL FORGING PRESS SHOWING PUNCHES FOR PIERCING THE SHELL BLANKS.

To enable the flywheel to assist the 1,800 horse-power motor to drive the two 1,200 kilowatt generators, during maximum demand periods, an automatic slip regulator has been installed, which introduces resistance in the rotor circuit as the output to the set increases, the speed thereby being reduced and a portion of the flywheel energy utilized for driving the two generators. Reducing the load on the generators automatically cuts out the resistance, and as the speed increases, energy is again stored in the flywheel.

The speed and direction of the rotation of the 3,000 horsepower motor are controlled by changing the polarity of the generators and varying their field strength, thereby varying the voltage applied to the armatures of the mill motor. This eliminates rheostatic losses except in the field circuit and permits any desired speed to be obtained independent of the load. As a result of this arrangement, no peak loads are taken off the line and the current input to the motor-generator set is maintained practically constant. The blooming



INSPECTION DEPARTMENT FOR SHELL FORGINGS.

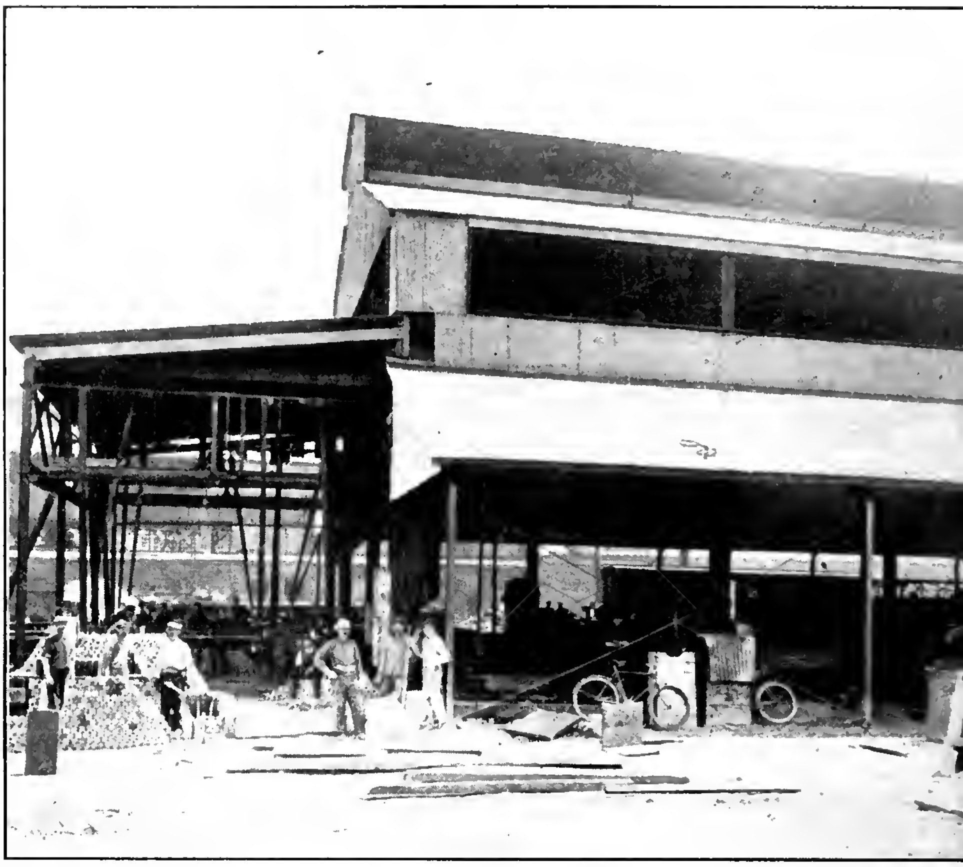
mill motor complete weighs 429,000 pounds, and the rotating part, which operates at a maximum speed of 100 revolutions per minute, weighs 164,000 pounds. This motor is provided with a thrust bearing on its shaft and a braking coupling is installed between the bearing and the pinion housing. The flywheel set weighs 367,130 pounds, and the rotating part weighs 240,000 pounds.

Ventilation is provided by a Sirocco fan installed by the American Blower Co., Detroit, which has a capacity of 24,000 cubic feet of free air per minute.

Forging the Shell

The round bars, from which the shell forgings are made, are of considerable length and must be cut to an exact size so that excess material or waste is reduced to a minimum. The bars or "rounds" as they are termed by the trade are cut off by electrically driven cold saws as illustrated on page 472. This photograph shows one of several machines which are engaged continuously on this work. The long bars are clamped in a frame or rest which holds them in a curved position corresponding to the curve of the circular saw so that all five bars are cut through simultaneously, and no time is lost waiting for the last bar to be finished by itself as happens in some cases.

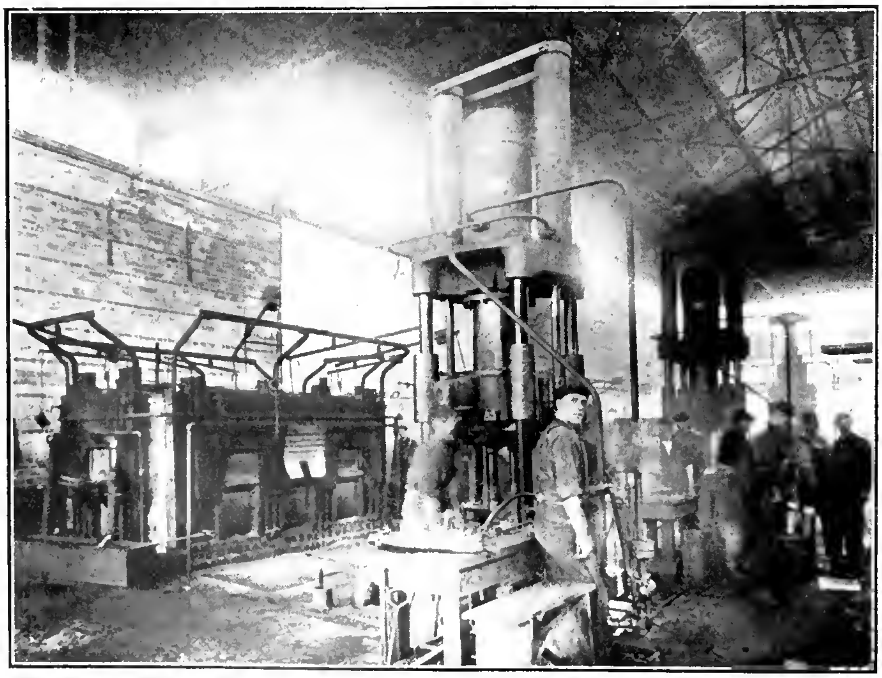
All forgings for shrapnel and 4.5-inch shells are produced by hydraulic presses, the two-operation method being adopted as the most satisfactory. In order to handle the immense volume of work involved, an entirely new forging shop with complete equipment was installed and has already produced innumerable forgings for both shrapnel and 4.5-inch high explosive shells.



FORGING SHOP ERECTED FOR PRO

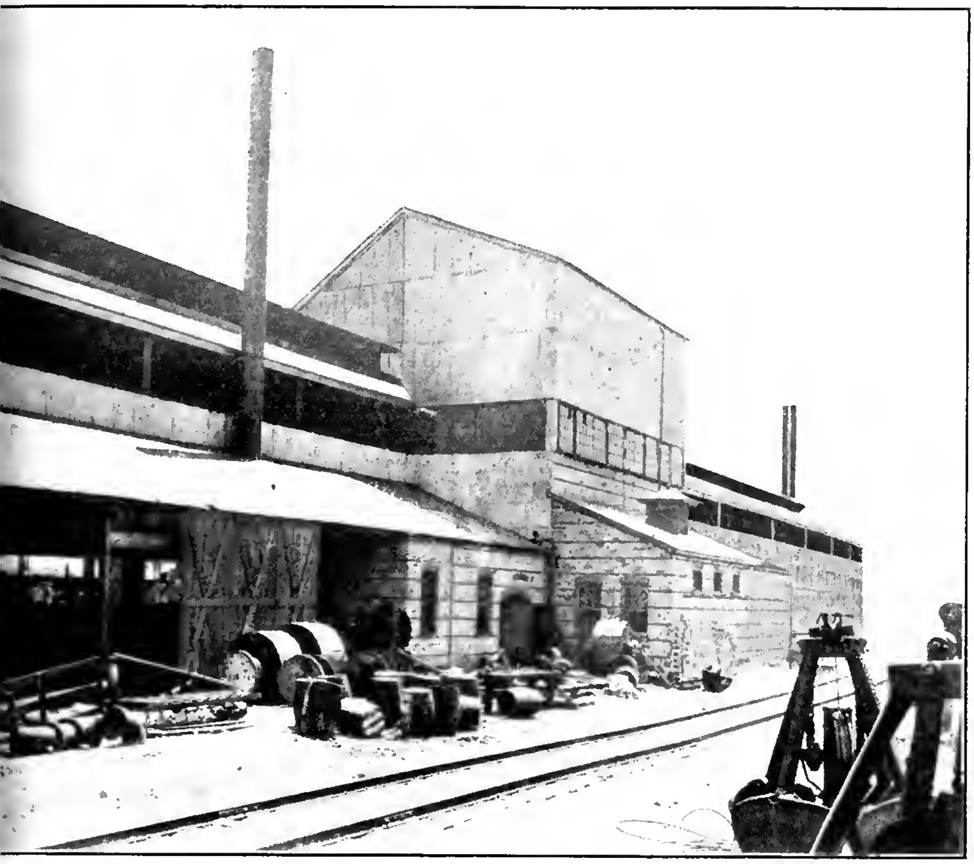
From the cold-sawing machines, the billets, as the pieces are called, now proceed to the heating furnaces where they are carefully brought up to the necessary temperature. The shrapnel billet is $6\frac{1}{2}$ inches in length by 3 5/16 inches diameter and is forged at a temperature between 1,900 to 2,100 degs. F.

The process of forging as performed here consists of two operations, viz., piercing the solid billet, and then drawing the pierced billet out to length, this second operation including cupping or forming the pocket for powder cup. The north portion of the building is devoted to shrapnel forgings exclusively while the south end houses the 4.5 department. Each installation is complete with numerous hydraulic presses, heating furnaces, etc., the hydraulic power being supplied from a central station on one side of the building at the centre. Views of these departments are shown on this page, also the stock of finished forgings undergoing inspection by government officials. When piercing, the hot billet is placed in a cup-shaped die, and a round nose punch is forced into it causing it to fill out and extrude upwards around the punch. Suitable stripping gear removes the pierced billet from the die, and it is immediately transferred to an adjoining press for cupping and drawing.



VIEW IN SHRAPNEL FORGING DEPARTMENT.

In order to form the interior to the desired shape, the point of the drawing punch is made to the proper outline and the press is moved downward forcing the punch into the bottom of the billet which rests in a cupping die placed in position temporarily. Solid stops are arranged to arrest the travel of the punch at the required point after which the punch with the forging on it is raised slightly to allow the cupping die



NGS FOR 3.3 IN. AND 4.5 IN. SHELLS.

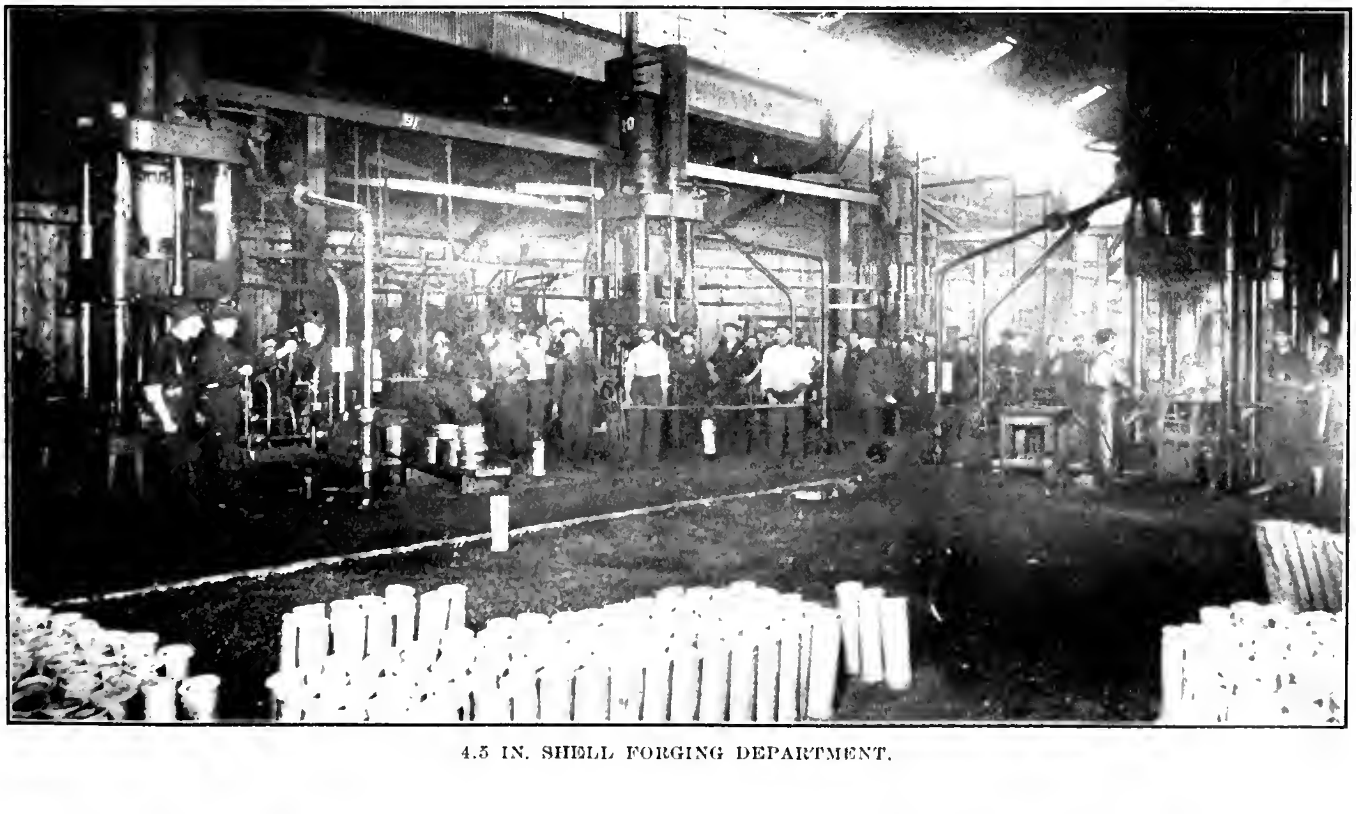
to be removed. The punch is now forced down through the drawing dies which draw the hot metal up around the punch giving the proper outside diameter to the forging which now has the form of a tube with one end closed.

The finished forgings are now deposited on end in large groups on a cinder floor which retards the cooling sufficiently to avoid any trouble due to air hardening, etc. As each forging leaves the drawing press, it is stamped with a number indicating the heat or melt of metal from which it is made, and is gauged for depth of bore and thickness of wall. After cooling it is finally inspected and marked after which it is transferred to the machine shop for completion, or forms one of the great number of forgings supplied by the company to numerous machine shops throughout the Dominion, engaged in machining and assembling shells and components.

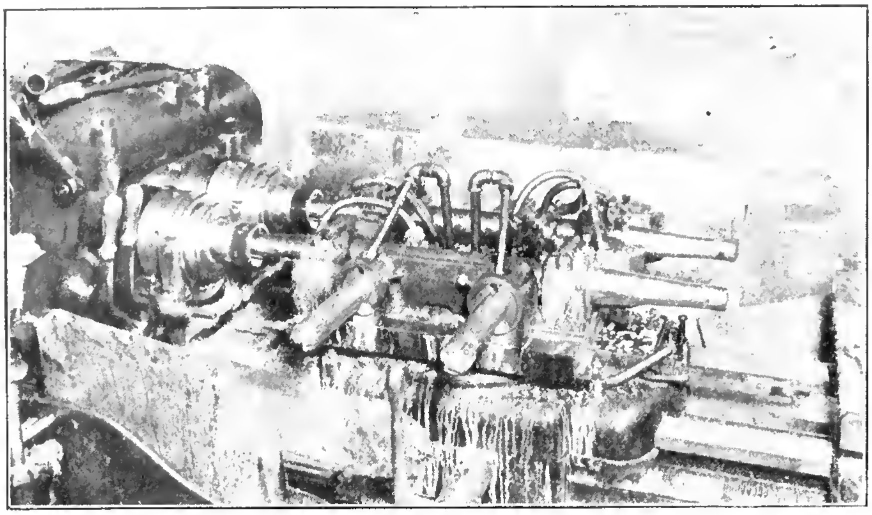
Finishing and Loading the Shell

The machining of the shell forging is done in fully-equipped machine shops, where the various operations, with which so many of our workers are familiar, are performed with all possible haste. Cutting off the rough forging to length, turning, boring, waving form the preparatory work followed by heat treating and nosing, after which threading, fitting base plugs, finishing to exact shapes and weights are all necessary before the shell is delivered from the machine to the assembly bench. Here may be seen the bullets being packed and the resin poured in to form a solid mass, which will behave in the desired manner while traveling through air from the muzzle of the gun. Varnishing the interior of high explosive shells is an operation that has to be thoroughly carried out in view of the deleterious action of the explosive on bare metal.

The assembling of the copper bands by hydraulic presses is one of the most interesting of the many operations which conclude with the painting and boxing of the projectiles, which then await shipment to the fixing plant to receive the charge of propellant contained in the brass cases which ultimately strew



4.5 IN. SHELL FORGING DEPARTMENT.



BORING EQUIPMENT ON DOUBLE SPINDLE J. AND L. FLAT TURRET LATHE.

pany's sentiments received concrete expression in the form of an athletic field, which is the home ground of a ball club of no small ability. Situated in front of the main offices, club room and library buildings, this expanse of green contrasts pleasantly with, and forms a welcome oasis in the midst of furnaces, mills, forges, machine shops, and railroad tracks.

The creature needs and comforts of all members of the staff are most carefully attended to in the staff building. A club restaurant, library, rest room, accident ward and hospital for sick and injured, are a few of many evidences of the reciprocal spirit of the plant, and in maintaining the surroundings in a high state of artistic excellence—well-kept grounds, vine-clad buildings, expert landscape gardening, etc.—the company betrays that attention and consideration for every detail, which has been an all-important factor in placing it in the enviable position which it now occupies as one of Canada's leading industrial establishments.

the battlefield in the region of artillery engagements.

The Spirit of the Plant

The vagaries of fate are well illustrated by the fact that while "doing their bit" in producing the much-needed material required by the Empire, the company, adhering to the most modern business policy, is an admirable exponent of the humane principles of "safety first." The mutual consideration for each other's interests which exists between the company and its army of employees is well evidenced by the environment of harmony which permeates the atmosphere of the entire organization.

In the midst of industry and activity, heat, smoke, grime, and other inseparable features of steel manufacture, the company has not failed to realize its moral duty to those whose toil and effort, both of brain and muscle, have helped to establish and maintain the position of the company in the foremost ranks of Canadian industry.

Firm believers in that old adage, "a sound mind in a sound body," the com-

FORMING BASE RECESS IN SHRAPNEL SHELLS.

SPECIAL WELDING METAL FOR IRON AND MILD STEELS

THE necessity for using welding metals specially made for the oxy-acetylene welding process should be recognized by all users of the process, says the Acetylene and Welding Journal.

Until recently no special welding metal for work on iron and mild steels existed, and it is well known that until the advent of such a metal, wires or rods of Swedish iron should be used in preference to all other welding metals. The French Welding Union have been carrying out a series of experiments with the object of obtaining a welding metal for iron and steel which would deoxidize the welds, increase their strength and more important still, increase their ductility.

Such an investigation is naturally a slow process because each rod made to a new or corrected formula must be followed by a series of practical and mechanical tests. These important researches were nearing completion and were to have been published in due course when the war intervened and the labors of the Union were turned in other directions.

It is well to emphasize that, apart from the welding rod, there are other conditions which must be rigidly followed if good welds on iron and steels are desired. It is safe to say that in the majority of workshops using the process these conditions are unfulfilled and advice on, say, the preparation of the edges, the power of the blowpipe and its position, the regulation of the flame and the execution of the weld itself could be given. Thus defective welds would, in many cases, be obtained with a perfect welding metal.

The use of ordinary iron or mild steel wire or rods is not to be recommended where sound strong welds are required. The use of Swedish iron gives a distinct improvement, but the welds obtained are still imperfect. The presence of impurities in these metals exerts a bad influence on the welds. The chief impurities being sulphur and phosphorus. A special welding metal for the welding of iron and mild steels has recently been placed on the British market under the name of Ferrox, and this product is manufactured entirely in England by a British firm's patented process. The metal is obtained by subjecting ordinary iron. steel, or cast iron to a process whereby the metal becomes impregnated with extremely finely divided nickel. and also holds in a state of occlusion or chemical combination a considerable quantity of hydrogen gas. It is claimed, after considerable research, that the welding rods obtained by this process effectively eliminate and counteract the disadvantages of the welding process. An example of the method of carrying out the invention is as follows:—

Hydrogen gas is passed over powdered nickel, or nickel oxide so that nickel chemically combines with the gas. The gas, thus charged with nickel is passed into a closed vessel in which the material to be treated is contained. The temperature and time of treatment play an important part. The gas is continuously passed over the metal or rods under a pressure slightly above atmospheric pressure. The time of treatment and the temperature employed will necessarily vary with the degree of impregnation required, with the thickness of the iron treated and its quality. When the treatment has been effected the product is cooled down in an atmosphere of hydrogen, or other inert gas.

Among the principal results obtained by applying this patented process are:—

(a)—The elimination of all oxides from the original material from which the welding wire is manufactured.

(b)—The expulsion from the original material of occluded gases.

The increased cost of this scientifically manufactured product over ordinary welding wire is small, and it is claimed that in spite of its increased cost, its use is attended with real economy. Apart from the relative merits it is cheaper than Swedish iron. In fact, the welding rod forms a very small percentage of the total cost of a weld.

EXPANDING MANDREL

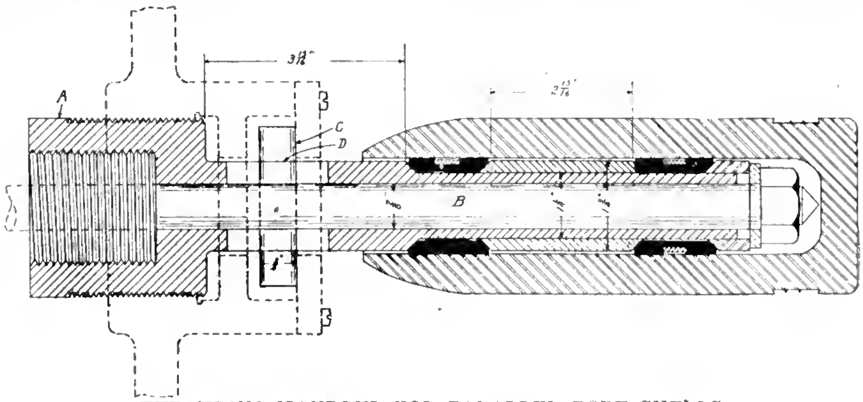
By E. T. Spidy

AS many of your readers are aware, the manufacture of munitions has called for much originality in designing tools and fixtures, partly because of the necessity of converting regular lines of machines which were adapted for work of a different nature, and partly because of the hurry in which they have had to be put into service.

One of the most called for pieces of mechanism at the present time is the expanding mandrel and every shop has its own variety to meet its particular requirements. It is a well-known fact that long holes are often not perfectly straight, particularly after the drill becomes worn. This may be accounted for in that a drill may strike a hard spot in the material and thereby glance a few thousandths of an inch to one side.

The mandrel illustrated was designed to average up the hole so that a "mean" along the total length would be obtained. It consists of a body A, which is threaded to suit the machine spindle. The body is bored out parallel and a spindle B, is fitted closely to its bore. At the lathe spindle end a cotter C is fitted through this spindle and corresponding slots D are milled in the body to allow for the travel of the cotter to tighten or slacken off the mandrel. On the outside of the body on the end inserted in the job, two steel sleeves are fitted and then split into three pieces. These three sections are held together by a retaining spring placed in groove shown for that purpose. Between these split sleeves a solid sleeve is placed which acts as a spacing block and also transmits the power applied by the centre spindle, through the nut and end bushing. It can be seen that when the spindle is moved towards the lathe spindle all the taper faces act in unison but do not tighten up until both split sleeves are engaged in the hole. Thus a hole tapered in either direction, or a hole out of line in any direction is held rigidly and at an average trueness. Any user of mandrels will appreciate this advantage because the style of mandrel in common use presses out the dogs in such a way that only a parallel hole is held along its total length solidly in such a manner that will produce accurate work.

The manner of tightening the mandrel into the job must be adopted according to the work requirements and the machine. For centreing purposes it is sufficient to attach a hand lever to directly engage the cotter, while for heavy turning in a lathe with a hollow spindle it is necessary to extend the spindle through the headstock and to attach a handwheel and a screw on the end of the lathe headstock and to attach a handwheel and a screw on the end of the lathe headstock.



EXPANDING MANDREL FOR PARALLEL BORE SHELLS.

When the lathe has no hollow spindle and heavy duty is required, the body of the mandrel may be threaded on the outside over the part screwed on to the lathe spindle and a handwheel threaded to fit this thread. The boss on the other side of the handwheel is extended to reach the cotter and a plate fitted over same so that the cotter is free to travel up the mandrel with the motion of the wheel in the recess so formed. This latter method is the most simple to apply and is entirely successful in operation.

Expansion joints should be located in all approximately straight pipe lines at such intervals that the extreme change in the length of pipe will not exceed the safe travel or range of the expansion element and that the force or strain exerted in moving the length of pipe may not be excessive and start leakage.

Large Shells: Production Problems and Possibilities--I.

By C. T. D.

In preparing to undertake the production of large shells up to 9.2 in. dia., manufacturers will encounter problems of a nature altogether different from those connected with 18 pdr. shells. Automatic machinery will not be so applicable to the larger sizes, and productive ability will centre largely on such points as sequence of operations, tooling methods, etc.

IN undertaking the production of large shells up to 9.2 in. diameter, Canadian manufacturers will find considerable opportunity for utilizing all the experience obtained in making the smaller sizes, while at the same time many important differences, both in design and size, will be found which will require just as careful planning and carrying out as any of the initial problems encountered in shrapnel manufacture.

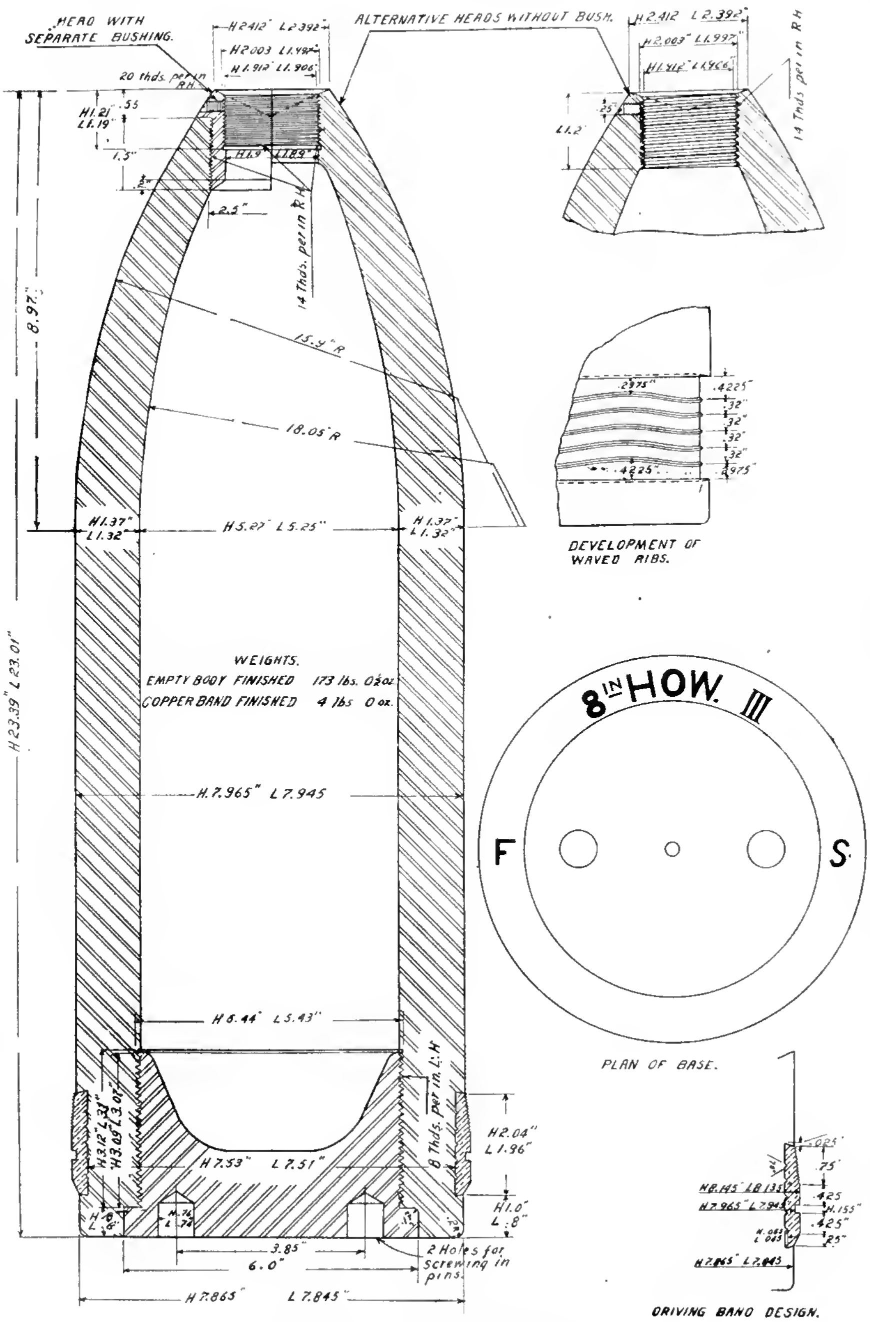
In producing shrapnel, difficulties were met which were peculiar to that type of shell, due to certain features of design and physical requirements. Buckling of the nose and walls, variations in heat treatment for different brands of steel, excessive wear on taps and tools due to irregularities in physical properties of the metal and so forth are some of the more familiar troubles which have been experienced by almost all producers of shrapnel.

The advent of high explosive 18 pdr. and 4.5 shells removed most of those previous troubles, to be succeeded by those incident to the insertion of the base plug, though the choice between a plain plug with a peined joint, and a threaded plug offers an alternative which has certain desirable features.

A study of the drawings of forgings and finished shells, which we reproduce, shows certain variations which will determine to a considerable degree the procedure adopted by different makers.

The various sizes of shells may be divided into two main groups, viz., solid base, and open base. The 60 pdr. and the 6 in. shell belong to the first group, while 8 in. and larger form the second.

Considering the solid base designs, the inserted disc in the base is common to both the 60-pounder and the 6-inch. The use of threaded discs or plugs although more costly than the plain system, is preferred by many manufacturers because of the smaller possibility of rejections. In order to ensure contact over the entire surface of the disc, it is made slightly convex so that when tightened up, the contact commences in the centre and spreads over the surface as the thread tightens.



8-INCH HIGH EXPLOSIVE SHELL.

The special machines now available insure the production of perfect threads and a satisfactory job with ordinary care.

In the case of plain discs, these are made a fairly close fit, allowing for escape of imprisoned air. The outer edge is bevelled slightly and a ridge or bead left on the mouth of the hole is riveted over. The riveting gradually draws the plate down flat after which a finishing cut removes all traces of the operation.

The bore of the 60-pounder shell closes in at the mouth, necessitating nosing in, while the 6-inch shell is made with a parallel bore, the lower face of the socket being well hollowed out to form an approximately hemispherical upper end of the interior. In the event of a shortage of steel bushings, makers might be called upon to supply 60 pdr. shells with solid bushings, as has been done in some cases with 4.5 shells. The reduced size of boring bar and increased overhang of cutting tool are serious handicaps when finishing internal profile in this case.

The principal remaining difference is in the design of driving band. In addition to being more complicated in profile, the 6 in. band is featured with an undercut which calls for increased care in production and also in handling.

The principle of construction adopted in these shells is radically different from

that of the 6 in. size and under.

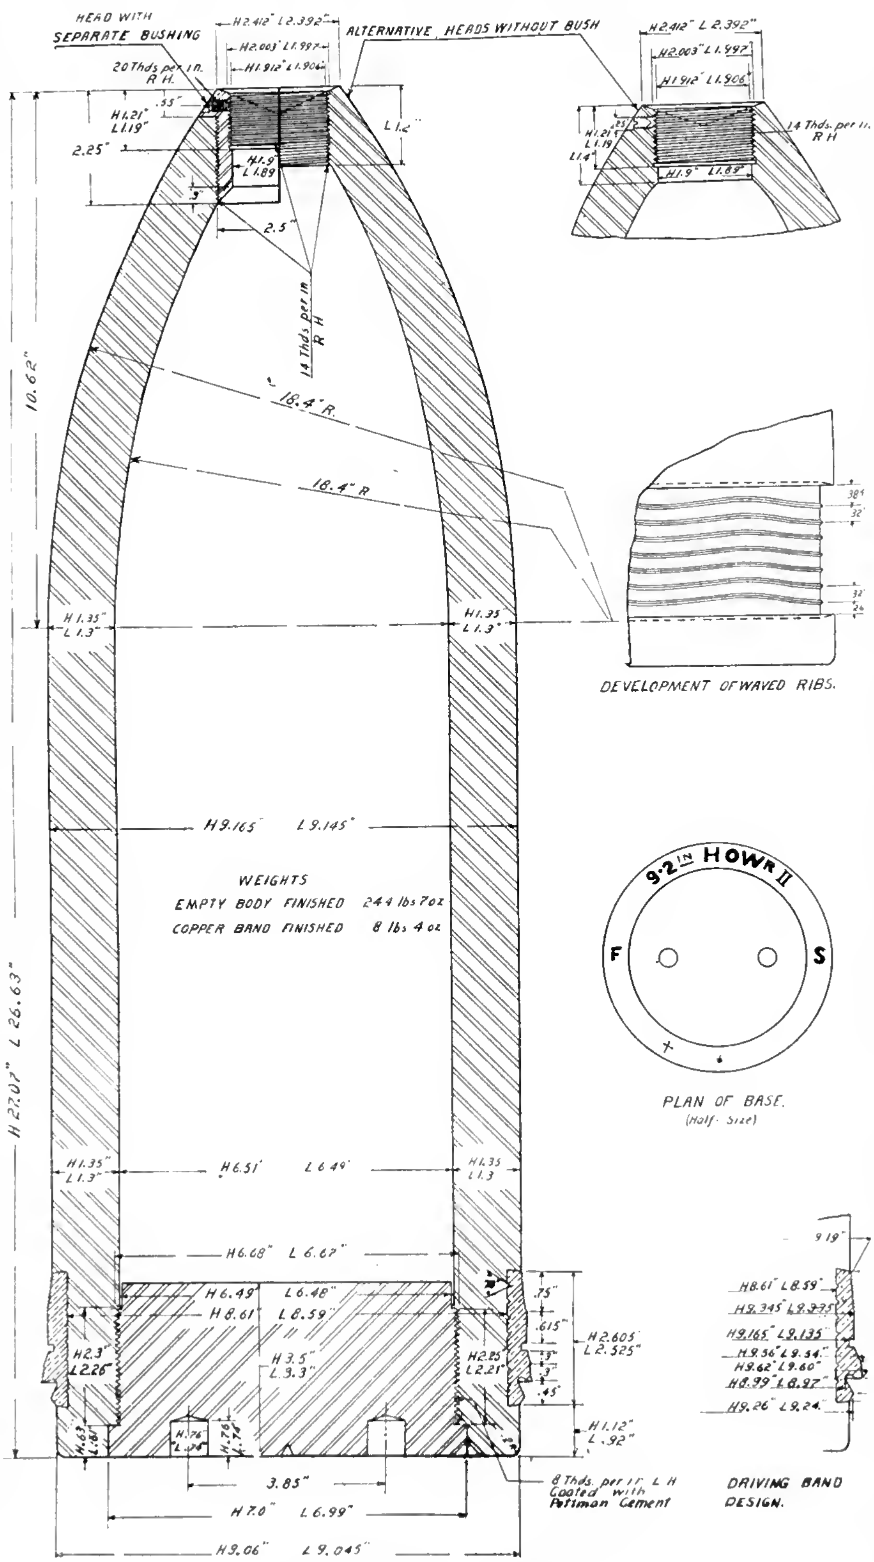
8-in. and 9.2-in. Shells

In place of being made with a solid base and open-mouth necessitating a nosing operation, etc., these shells are forged with the nose closed or solid, and the base open. A solid forged steel plug with ample length of thread renders it possible to make a perfectly sound gas-tight joint, capable of withstanding the intense heat and pressure of the exploded gases.

The first question which presents itself to the practical mind is that of machining the bore of the shell. Machines for performing this operation have been in use in the regular arsenals and munition factories right along, but the private firms undertaking this work for the first time will in most cases develop their own ideas, as in the case of the smaller shells. Methods of machining open base shells will develop round the manner of boring. In one case the shell will revolve and boring bars and cutters will be fed into it in the conventional manner. In the other case, the shell will be held rigidly in a cradle and fed on to a revolving cutter bar.

In either case the best way to start is to work from the inside of the shell outward. It may not appear so to all, and it may not be compatible with certain methods and systems of machining, but those makers who are not yet committed to a definite method should bear in mind the fact that just as these shells are bigger than 18 pounders, so will their variations in the rough state be greater. A much quicker approach to the required degree of accuracy can be obtained by locating all operations from the inner surface of the shell as inequalities in the thickness of metal can be anticipated and removed more conveniently and effectively with a turning tool on the outside, than with a more or less yielding boring bar working out of sight.

The question of whether to make a separate or solid bushing is a matter for individual judgment on the part of the maker. If sufficient space is obtained without the bush then a slight saving in tap expense and time of machining is possible, coupled with the reserve possibility of enlarging the hole and using a bush should the first hole be spoiled in threading. A further consideration would be the non-liability to delay through the non-delivery of bushings from firms engaged in their manufacture.



9.2 INCH HIGH EXPLOSIVE SHELL.

It is perhaps desirable that the base plugs be made in the same shop as the shells. The making of these in separate establishments is quite in accordance with modern machine practice, provided gauges of close enough limits are used and care is taken to avoid damage to threads and surfaces in shipment and handling. The allowable limits on the thread diameters are generous and while supplied plugs might be just within limits in one direction, the shell might be just as close to the limits in the other direction, consequently trouble would arise in one case getting the plug into the shell, and in the other, getting the shell past the inspector.

By producing the plugs in the same shop as the shell, more satisfactory work can be accomplished, as once having determined on a no-limit size for the plug, all available limits can be taken advantage of in tapping the end of the shell.

Driving Bands

A considerable difference in profile between 8 in. and 9.2 in. bands exists, and in the absence of any obvious reason or official explanation, the requirements have simply to be fulfilled. As in the 6 in. shell, the 9.2 in. band is shown having an undercut which does not simplify matters. The numerous vee grooves call for particular care not only in machining but in securing properly annealed copper so as to produce perfect outlines. Banding presses of greatly increased power are necessary in view of the increased dimensions of the band.

The assembling of the plugs offers op-

portunities for the development of plug driving machines for tightening plugs by power assuring efficient and uniform results.

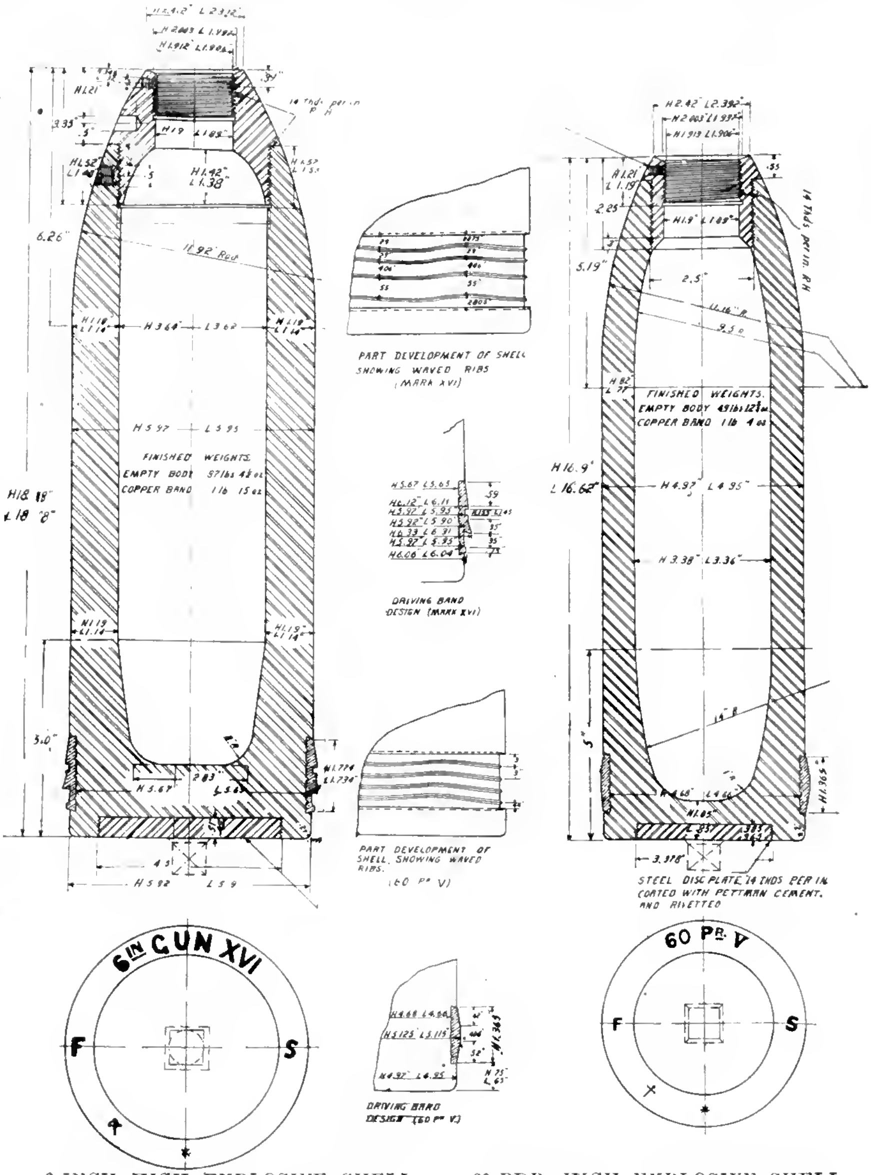
Not the least important of equipment developments lies in the necessity for power handling apparatus.

Prospective makers of these large shells will be well advised to approach the driving band feature with all possible deliberation and care. The great increase in size, as well as the intricacy of outline, makes it an entirely different proposition from 18-bands. The band profile of the smaller shells is comparatively simple, and the circumference about one-third that of the big bands, both of which facts conduce to a large output in numbers from a single set of forming tools.

Whether the present methods of band turning will be entirely satisfactory on these large bands is a point that can best be decided from actual experience. The possibility of developing a special profile miller seems not altogether remote, and from a theoretical standpoint offers certain advantages. Revolving a heavy forging at a high rate of speed in order to remove a small quantity of metal from a minor component is bad practice, not only from a power saving point of view, but from quality of production as well. Constant attention would be necessary to prevent heating up the steady rest, and any seizing of the shell with consequent scoring might easily cause enough damage to result in rejection. This fact alone would justify consideration being given to the use of a milling machine in which the heavy shell body would be revolved slowly while a formed milling cutter produces the profile on the band.

Several developments of design suggest themselves such as a multiple spindle milling device in which a roughing cutter fed into the work in front would remove the surplus stock and a sizing cutter behind would be elevated on a vertical slide till it was level with the centre of shell. If cutting compound had to be used to prevent the finer portions of profile from tearing, a copious stream would prevent heating of the band from spreading much beyond the parts being operated on.

The provision of a suitable tool with angular feed to undercut the band would seem necessary although it is more than probable that the fresh angle of attack, from which many of our manufacturers will approach these problems, will result in not a few ingenious and original methods and devices being produced.



6-INCH HIGH EXPLOSIVE SHELL. 60-PDR. HIGH EXPLOSIVE SHELL.

Threading the plug also offers opportunities for milling applications, possibly the tapping of the shell itself may be treated in this way.

Handling Apparatus

The increased weight of these large shells, both rough forged and machined, necessitates changes of a very radical nature in the ways and means of handling them not only in and out machines, but in course of transportation from one part of a factory to another.

From the time a forging commences to undergo the first operation until it is completed, or until a break in its progress is advisable, say at the banding press or enamelling oven, all its steps should be strictly in rotation so as to avoid any doubling on its tracks.

Where it is possible to do so, an overhead track, with travelling chain blocks or hoists, either air, electrical, or otherwise, will prove the most popular and efficient method.

Circumstances peculiar to certain shops may render preferable the adoption of small revolving jib cranes on each machine which would require the use of suitable transfer trucks for moving between operations. A well thought out arrangement of this nature might be much less costly and when properly used, just about as quick as an overhead track. Any doubling back that might be necessary on occasion would certainly cause little if any confusion with this system as compared with a track which would not allow movement in either direction when a job was being set up in a machine.

The production of forgings up to the 8-in. size is now an accomplished fact in this country, although some few weeks must elapse before 9.2-in. forgings are also in course of production. Reproductions of forging drawings which give a good idea of the probable amount of work which will be required and the detailing of different methods, with illustrations and descriptions of the machines and tools for use therewith will form the subject of future articles in these columns.

Bombs Made in Canada.—Bombs have been added to the munitions products which Canada is now producing for the British War Office. An order for 5,000 of these projectiles has been received by the commission, and is being placed for speedy delivery. The bombs are to be used in trench warfare, and are to be fired from what are known as mine or trench guns.

ANTICIPATING RESUMPTION OF PEACE-TIME BUSINESS

APPARENTLY of equal moment and importance to the manufacture of war munitions—perhaps even transcending the latter, is the manufacture of industrial stock values. From week to week these continue to advance, not seldom by leaps and bounds, and the question is naturally being asked: what is going to happen them when the end of the war becomes imminent?

Undoubtedly our steel and metal-working industries are finding munitions production worth while, but we hesitate to believe that the margin between contract prices and production costs is anything like so great as to justify the high level attained by the stocks. The impression has got abroad that our manufacturers are making huge profits on war orders, and that the war is being made the medium whereby a multiplicity of individual and corporate enrichment may be brought about. In any case, "It's an ill wind that blows nobody any good." Therefore, in spite of the devastating influences of and distress caused by this war of wars, a considerable number of people, here and elsewhere, will no doubt realize a bountiful harvest of hard cash by devious means and channels. Combat their doing so how we may, such a consummation will be inevitable.

It is generally conceded, and at first sight reasonably so, that, after the necessarily long period of neglect, much constructional leeway will have to be made up. The expectation then is that a burst of prosperity such as we have probably never known, will so efface the transition from war to peace that neither stock prices nor productive activities will be affected.

A boom is predicted in merchant shipbuilding to make good the losses by sinking, and to compensate for the almost total extinction of vessel construction in Britain. A similar boom is predicted in the sphere of railroad betterment, to compensate again for the long period during which maintenance has been neglected and earnings conserved. Development work of every description, private, municipal and Governmental, is, we are told, to be no exception; thus, on paper, the end of the war seems to be desirable for a variety of reasons.

In all calculations or prophesies of the nature of the foregoing, no cognizance, however, is taken of the price we are having and will have to pay for the war. We forget that in addition to war stocks reaching giddy heights, material and labor, and all else have pyramided. Stock market prices have a knack of crashing down en masse when the opportune moment arrives; not so these others.

Steel, wages, food and clothing are largely interdependent and have a comprehensive application. They are usually super-sensitive to the upward turn, and during the past year have proved so on many occasions. Individually or collectively they are less sensitive to the downward tendency, be the latter of simple desire or judiciously applied force or pressure. The downward movement is not only hard to start, but is so slow and gradual as to be almost imperceptible of measurement.

With the end of the war in sight, attention will, as already indicated, be turned to the peace-time pursuits of shipbuilding, railroading, etc. It will be found, however, that shipowners, railroad executives, etc., continue to sit tight so far as the distribution of orders is concerned, the cost of raw and finished material for the purposes of their requirements being totally prohibitive from the standpoint of the then or immediately prospective earnings. War-time prices for equipment and supplies will match ill with peace-time revenue. A period of readjustment must needs be ushered in, during which business of every description will incline to languish, war stocks will disappear and plain industrials will take their place. Prices of raw and finished material will have to be marked down, however slowly and reluctantly those involved contribute to the process.

Only by producers and their help getting together now, without waiting for the end of the war to become more imminent, and planning the necessary and inevitable procedure when the time is ripe, will the transition period be shortened and perchance eliminated, and a prolonged and wholly unnecessary business depression be avoided. Capital and labor are equally interested in the matter and both will be called upon to make big concessions sooner or later. The general welfare of our people demands that they take time by the forelock and arrange the details now.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, Que., Nov. 15, 1915.—Favorable industrial conditions continue throughout the Dominion. In the iron and steel trades, the activity is quite unparalleled, and the possibilities are that the immediate future may see even greater developments.

The manufacture of steel promises to crowd the capacity of every mill both in Canada and the United States. In this connection it is interesting to note that one hundred years ago the United States were producing about 50,000 tons of pig iron a year, while the average daily output for October last was over 100,000 tons, or an increase of 600 to 1.

The pressure being felt by the steel mills is largely due to the demand for war supplies, not only in shell bars and billets, but in many other lines, such as steel rails, structural steel for cars, locomotives, automobiles and the countless necessities used, directly, or indirectly, for the maintenance of large armies in the field.

Previous to the breaking out of hostilities, Canada as well as other countries countries, was purchasing large quantities of chemicals from Germany. Brought face to face with the problem of supplying their own needs, or paying prohibitive prices for what little could be obtained, the Canadian chemists have not only succeeded in accomplishing remarkable results in the production of these much-needed chemicals for their own use, but are able to export to Britain.

Enlarged opportunities have been opened for Canadian manufacturers, not only for supplies relative to war munitions, but in all classes of trade, formerly monopolized by European nations.

Steel.

The steel trade continues at quite high pressure, every available mill working to the limit, in the endeavor to supply the abnormal demand for bars and billets, as well as to keep up with the gradually increasing commercial requirements. The stress placed upon the steel-producing plants on this continent is shown by the past week's reports, in which it is stated that the United States Steel Corporation have withdrawn all prices on steel products except tubes and pipes. They are practically out of the market on all other lines of steel. Delivery under nine months is almost impossible, and many plants are closing down on future orders, until they can state definitely their exact position.

The requirements of the finishing mills are beyond the output of crude steel, and one of the necessities of the moment is to bring the production of the basic material up to the output of the rolling mills.

Canadian furnaces are only producing about one-half of the steel being used by our manufacturers, and any restriction placed upon importation would have a serious effect meantime.

Construction of large additions to the plant of the Nova Scotia Steel Co. are now being undertaken, and within three months new furnaces are expected to be in operation, producing 200 tons a day in addition to their present output. New equipment for the production of the larger shells is also to be delivered at New Glasgow in about six weeks. The mines in connection with this company will continue operations at high pressure throughout the winter months.

> **CANADIAN GOVERNMENT PURCHASING COMMISSION**
>
> **The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.**

Machine Tools and Supplies.

Activity in machine tools has received a new impetus because of the expectation that many firms will receive orders for the heavy type of explosive shell, as well as additional orders for the present shells of 3.3. and 4.5-inch type. Many inquiries have come in for machines suitable for the production of 6-in., 8-in. and 9.2-in. shells, and in a short time definite information may be received as to the successful firms receiving contracts for additional munitions.

The demand for supplies is as heavy as ever. The munition factories are working night and day, and small tools and other supplies are a constant requirement.

Metals.

The present situation in the metal market is little changed from that of the preceding week. However, the reported closing of the Suez Canal has created some excitement among buyers of spot tin with the result that the persistent buying to cover requirements has advanced the price from 38c to 45c a lb.

Copper is showing some signs of improvement, but last week's quotations prevail. Spelter is a shade stronger, and is quoted at 19c, and antimony shows an advance of five dollars per 100 lbs. A slight increase is noted in aluminum, a price of 62c being now quoted.

Copper.—The optimistic outlook for future copper is keeping the market firm. Although foreign quotations show advances, prices locally remain steady.

Tin.—Conditions in the Far East have apparently clouded the tin situation for the present, with the result that heavy advances have been made on prices for spot tin. Any losses of spot tin now in process of transportation might easily cause a further advance. This week's quotation shows an increase of $7 per 100 lbs. over that of last week.

Spelter.—Foreign advances in the price of spelter have not affected the local market very much. However, an advance of one cent per lb. is shown in this week's prices.

Lead.—This continues firm at 6½c per lb.

Antimony.—The apparent scarcity developing in antimony and the demand has made the price stronger, the present quotation being $40 per 100 lbs.

Old Materials.

Business in scrap metals of all kinds has been fairly brisk during the past week, and a general advance is noted in many lines. Copper has advanced about $10 a ton, considerable quantities being handled.

Business in heavy melting steel has increased the price ½c per pound.

Heavy melting lead has risen to $5 per 100 lbs., and tea lead shows an increase of ¼c per pound. Scrap zinc is selling at 12½ cents.

Toronto, Ont., Nov. 16.—The recent action of the United States Steel Corporation with regard to the Canadian market shows conclusively the far-reaching effect which the war is having on the steel trade here and elsewhere. The situation has been caused entirely by the enormous demand for munitions which will increase now that the orders for the large calibre shells are being placed. No official list of successful tenderers will be given out, nor the size of the orders named, notwithstanding reports to the contrary. This is the wish of the British War Office, which has notified the shell Committee to that effect. It is understood that some orders for 6-in. shells have already been placed and that the contracts for the larger shells, although not actually signed up, are practically assured to certain firms.

The general industrial situation is gradually improving and a more confident spirit prevails as a result. A large

number of factories are engaged in the production of war equipment and the engineering trade is active on shell orders. Prices of all lines have a higher tendency, particularly iron and steel products, which continue to advance. The metal market is very active and a general advance in prices has to be noted.

Steel Market

The recent announcement issued by the United States Steel Corporation is of considerable importance to Canadian steel plants. The Corporation in addition to withdrawing prices to the Canadian trade, have decided not to solicit business in this market until conditions have become normal. This order will affect principally bars and billets, etc., for which there is such a heavy demand; structural shapes will also be affected. This action of the Corporation does not mean that they will refuse business, providing delivery is no object, or that orders already booked will not be filled. It is simply a question of delivery. The demand is so far ahead of production that the output of the mills is booked up for several months in advance. Under these conditions and with unfilled tonnage increasing each month, prices cannot be fixed so far ahead and no promise can be made to consumers when they are likely to get delivery. The situation thus revealed is unprecedented and while not particularly serious at present may become so as the demand for steel for munitions continues to in increase and present contracts run out. The market is naturally upset and the outlook is uncertain.

Canadian steel companies, although operating on capacity, are falling behind in meeting the demand, and higher prices for steel products are inevitable. The prosperity of the steel industry is assured for some time to come and plants will have to be extended to take care of the demand. It is announced that the Nova Scotia Steel Co. will build an open-hearth furnace having a capacity of 200 tons per day. The same concern will install new presses for forging 8-in., 9.2-in. and 12-in. shells, also the necessary machining equipment.

Prices continue in an upward direction. Canadian mills are now quoting bars at 2.50c base, and reinforcing bars 2.35c base Toronto, plus extra for twisting. Steel bars are 2.50c and small shapes 2.75c f.o.b. Toronto warehouse. Pittsburgh bars, plates and shapes for Canadian consumption are quoted at 1.60c, but this figure is practically nominal, as no orders are being booked. Seamless boiler tubes have advanced again, but lapwelded are unchanged for the present. Higher prices on tubes are expected. Boiler plates are very firm and an advance in price may be made early next month. Some lines of bolts and nuts have advanced, the new discounts being as follows: Coach and lag screws, 70 p.c.; machine bolts, 3/8 in. and less, 65 p.c.; machine bolts, 7-16 in. and over, 50 p.c.; blank bolts and bolt ends, 50 and 7½ p.c.; square nuts, 3¾c per lb. off, and hex. nuts 4½c per lb. off. Another advance in wrought iron pipe has been made and is now in effect. The new schedule affects black pipe only, galvanized remaining unchanged.

Prices of high-speed tool steel continue to advance and the situation shows no improvement. The scarcity of tungsten has assumed serious proportions and the supplies, although increasing, are not sufficient to meet the demand. As this alloy to a large extent determines the price, quality and quantity of high-speed steel, it is apparent that while tungsten keeps at the present high level, high-speed tool steel will also be correspondingly high. The situation is further aggravated by the exceptionally heavy demand, which is at least five times that of normal.

Prices of all descriptions of steel sheets are very firm, and higher prices are expected. In galvanized sheets, the differentials between the gauges continue upset by the abnormal spelter situation, and while the consumer may secure heavy gauges at comparatively low prices, he must pay higher price for light gauges. Acid is becoming scarce and is high in price, and this, together with spelter and black sheets becoming more costly, will not doubt cause galvanized sheets to advance. Bessemer black sheets are quoted at 2.15c to 2.25c and open hearth 2.25c to 2.30c Pittsburgh.

In the States prices continue to advance, but this has had no effect in curtailing the demand, which is heavier than at any stage in this present movement. The unfilled tonnage of the United States Steel Corporation for October shows an increase of 847,000 tons over September. This record shows the development which is taking place in the market. The heavy demand for billets continues and prices are very firm. Wire rods are higher at $35 f.o.b. Pittsburgh.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Messrs. S. Ruperti and Alexsieff, care Military Atache, Russian Embassy, Washington, D.C.

Pig Iron

The heavy demand for steel making pig iron continues but foundry grades are quieter. Prices are firm but unchanged.

Old Material

The market is considerably firmer and quotations higher for some metals. Copper is very strong and prices have advanced throughout the list. No. 1 machine composition and No. 1 composition turnings have advanced about 25c per 100 lbs., while No. 1 wrought iron and heavy melting steel are also higher. Prices of scrap lead are higher and scrap zinc is also advanced. Complete prices are given in the selected market quotations. Business is improving, but the higher prices are due more to the general buoyancy in the market and improved tone.

Machine Tools

The placing of the orders for the large-calibre shells is resulting in increased activity in the machine tool market. Quite a number of orders for tools, principally lathes, have already been placed and others are pending. Deliveries are better on the larger size lathes than on the smaller tools. Second-hand tools suitable for shell work are getting scarce and are not so easy to get hold of. Prices on all tools have advanced considerably. A feature of the present situation has been the development of the single-purpose lathe for which there is a big demand. Special tools for making shells have also been put on the market with exceptionally satisfactory results.

Supplies

A number of price changes have to be noted again this week. Solder, half-and-half, is higher at 25c, due to strength in the tin market. Prices of gasoline and benzine have been readjusted to bring gasoline ½c higher than benzine. Gasoline is now being quoted at 23½c and benzine at 23c per gallon, in barrels. A sharp advance has been made in turpentine, which is now quoted at 85c per gallon. Linseed oil is higher and is quoted at 85c for raw and 88c for boiled oil. Business continues brisk.

Metals

The market has revived and is more active. Prices of practically all metals have advanced, tin showing the greatest strength. The sharp advance of tin is

owing to a belief that the Suez Canal is closed and also on account of submarine activity in the Mediterranean. It is likely that shipments of tin will be interfered with on this account. Copper has advanced, and there is a better feeling in the market. Spelter, lead and antimony are all higher and the market is strong, while aluminum is higher and quotations nominal.

Tin.—Both London and New York markets are excited, buyers being anxious to cover their requirements, due to the report that the Suez Canal has been closed. If such is the case there will be a delay in getting supplies, while there is also a chance of shipments being lost in the Mediterranean on account of submarines. This scare, together with a spot scarcity, has unsettled the market. Tin has advanced 8c locally and is now quoted at 48c per pound.

Copper.—There is a better feeling growing in the market and the London market is stronger. There is no special improvement noted in the demand from consumers, but producers are confident that the latter must become heavy buyers soon. Copper has advanced 1c and is quoted at 20½c per pound.

Spelter.—The market is firm and higher. A corner in spot spelter has developed in London and quotations have advanced. Spelter has advanced 1c locally, and is quoted at 19c per pound.

Lead.—There is a shortage of supplies of spot and early delivery in London, and the market has advanced. The market is strong in New York and the "Trust" price is slightly higher at 5.15c which may be advanced. Locally, lead has advanced 1c and is quoted at 7c per pound.

Antimony.—The market is firm and there are indications of a scarcity in spot antimony developing if the demand for prompt metal continues as good as it has been during the week. Antimony has advanced 5c and is quoted at 40c per pound.

Aluminum.—The situation does not improve, and supplies are very difficult to obtain. Quotations have advanced 5c and are nominal at 65c per pound.

Moose Mountain Iron Mines at Sellwood, Ont., have closed down indefinitely after a series of disappointing experiments of the past several years to commercialize the immense bodies of ore which they control. The most recent experiments were with the Grondal system of concentrating and briquetting the ore for shipment to the blast furnaces, raising it from a 35 per cent. ore in the rock to a 60 per cent. in the concentrates, which was not a commercial success. It is estimated that over a million dollars has been expended by the Gates interests of New York and the Mackenzie and Mann interests of Toronto in this endeavor.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Toronto, Ont.—The Canadian Hanson & Van Winkle Co. are building a brass foundry at a cost of $5,000.

Galt, Ont.—The Perfect Machinery Co. will build a machine shop to cost $4,000. S. L. Clark is general manager.

Chatham, Ont.—Park Brothers of this city have closed a contract with the Dominion Sugar Co. for $14,300 worth of machinery for the new plant.

Berlin, Ont.—Louis F. Dietrich has purchased a property which will be converted into a garage. An elevator and other equipment will be required.

Hamilton, Ont.—The Canadian Chadwick Metal Co. are having the old Gompf brewery building altered and machinery installed for making munitions.

Waneta, B.C.—The Waneta Development Co. will immediately start construction of a hydro-electric power plant to be erected at the confluence of the Columbia and Pend O'Reille rivers, which will have a capacity of 80,000 h.p.

Toronto, Ont.—It is officially announced that the Ontario Hydro-electric Commission has completed the survey for a Government powerhouse to be erected between Queenston Heights and Niagara Falls, Ont. Plans are being prepared. It is planned to use the surplus waters of the Welland Canal to develop 300,000 h.p.

Electrical

Hespeler, Ont.—The Hydro Commission will install a new transformer and also a number of 100 c.p. nitrogen filled lamps.

Port Lambton, Ont.—A petition has been drawn up asking for the hydro-electric system to be extended to this town.

Agincourt, Ont.—This village is planning to secure connection with the Hydro-electric at Duncan, on the C. N. R., and it is understood the preliminary arrangements are all completed.

London, Ont.—By a vote of 65 to 8, the ratepayers of the village of Granton, fifteen miles north of here, on Nov. 9 carried a by-law authorizing the village council to enter into a contract with the Hydro-electric Power Commission for a supply of power.

Stratford, Ont.—The council and representatives of adjoining municipalities met Engineer Gaby and officers of the Provincial hydro-radial union and approved of the general plans of the main Toronto to London hydro-radial line as it affects Stratford and district. A motion was adopted that steps be taken to have necessary by-laws submitted to the electors in January.

Municipal

Hespeler, Ont.—The town council will call for tenders for a pumping station.

Guelph, Ont.—The installation of fire alarm system is being considered by the City Council.

Hamilton, Ont.—Fire Chief Ten Eyck has asked for a new fire alarm system to be installed.

Chatham, Ont.—Hydro power will probably be installed in the pumping station this year.

London, Ont.—The City Council contemplate further extensions to the waterworks distribution system.

Tecumseh, Ont.—A new water distribution system is contemplated for this town. The cost is estimated at $25,000.

Owen Sound, Ont.—The town council have decided to submit a by-law to the ratepayers to authorize a loan of $12,000 to W. A. Wilson, of London, who will start a shoe factory here.

Regina, Sask.—The City Commissioners have decided to install a new pumping unit driven by electrical power at Boggy Creek. The new pump will have a capacity of about two and a half million gallons. The cost is estimated at $12,000.

Toronto, Ont.—The Board of Control have received a dozen tenders for the construction of the new Don incinerator building exclusive of the new chimney. The prices ranged from $84,500 to $95,000, several being $86,000. The Controllers awarded the tender to George Welof, whose price was lowest at $84,500, subject to the approval of that Street Commissioner. The chimney will cost about $9,000.

General Industrial

Hespeler, Ont.—The Porcelain Kitchen Furniture Co. will establish a factory here shortly.

Petrolia, Ont.—Fred Howlett has purchased a site and intends to erect a brick and tile manufacturing plant.

Preston, Ont.—The Solid Leather Shoe Co. contemplate the erection of an addition to their factory. Manager, J. Parker.

Thorold, Ont.—The Ontario Paper Mill here was damaged to the extent of $2,000 by fire on November 9. The fire originated in the large bin which supplies the coal for the boilers. The loss is covered by insurance.

Tenders

Grand'Mere, Que.—Tenders are being received for the supply of one 500 h.p. turbine and dynamo. Engineer, L. S. Pariseau, Montreal.

Toronto, Ont.—Tenders will be received up to Tuesday, November 23rd, 1915, for the construction and erection of smoke breeching at main pumping station. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

Halifax, N.S.—Tenders will be received by the Governor of the Province of Macao, up till January 8, 1916, for the supply of a steel, self-propelling dredges for the use of the Macao Harbor Works. Full particulars may be obtained at the office of Fred. H. Oxley, Consul for Portugal, Keith Bldg., Halifax, N.S.

Toronto, Ont.—Tenders will be received, addressed to the Chairman, Board of Control, City Hall, up to Tuesday, November 23rd, 1915, for the following: Asphalt, refined; brass and bronze castings; brass work for house services; bleaching powder; castings, pipe; castings, special; castings, manholes, etc.; general supplies; house numbers; hydrants; iron and steel; lead pipe; mineral dust; oils; rubber valves, etc.; stop valves. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

Personal

Frank Chappell, town engineer of Oshawa, Ont., has resigned his appointment to accept a position with the McLaughlin Motor Co., Oshawa.

Wm. Weir, of Montreal, president of the Canada Foundries and Forgings, paid a visit recently to the Welland plants, Canada Forge and Billings & Spencer.

William Bissett Smith, general manager of the Dominion Transport Co., died in Montreal on November 8, in his 87th year. He was born in Huntley, Aberdeenshire, and came to Canada in 1855.

Frank W. Hinsdale, who, after spending a year and a half in helping to organize the work of the Ontario Workmen's Compensation Board, has completed his duties, and has left Toronto for New York.

W. P. Hinton, assistant passenger traffic manager of the G. T. R. and G. T. P., has been appointed traffic manager in charge of passenger and freight of the G. T. P. R., with headquarters at Winnipeg, also Western traffic manager of the Canadian Government Railways.

C .H. Cahan, Jun., of the Canadian Car and Foundry Co., was in Pittsburgh recently with three members of the Imperial Russian Commission. They visited a number of important industrial plants with a view, it was stated, of ascertaining just how soon certain orders they desire to place could be filled.

Refrigeration

Chatham, Ont.—A proposal to establish a municipal dairy is under consideration by the council.

Ottawa, Ont.—The Ottawa Dairy Co. has let the contract for the erection of an ice-making plant to cost $15,000.

Toronto, Ont.—The Board of Control has sanctioned an expenditure of $9,500 for additional cold storage rooms at the Municipal Abattoir.

Rigaud, Que.—Curtis & Harvey have their storage rooms equipped with -ton refrigerating machines, fur- by the Frick Co., Waynesboro,

Wood-Working

George Guentzler will to his woodworking

London, Ont.—The George H. Beton Lumber Co. is planning to add electrical equipment to operate woodworking machinery.

Nelson, N.B.—Fraser, Ltd., Fredericton, N.B., intend to erect a large sawmill at this place. Approximate cost, $100,000.

Rimouski, Que.—Work is about to start on the erection of a shingle mill for Price Brothers & Co., Quebec. Estimated cost, $15,000.

St. John, N.B.—A site has been purchased at Washademoak, N.B., by Daley & Carvell, of this city, on which they will build an axe-handle and woodworking plant.

Marine

A. A. Larocque has been appointed vice-president of the Sincenes-McNaughton Line, Ltd., Montreal, in succession to the late Major A. V. Roy, who met his death recently while fighting with the Canadian forces in France. Mr. Y. Dupre was elected to fill the vacancy on the directorate.

St. Johns, Nfld.—The steamships "Adventure" and "Bellaventure" have been sold to the Russian government and will be used to keep Russian ports clear of ice in the winter. The "Bellaventure" has recently returned from Hudson Bay. Before leaving for Europe a trial trip will be run with Russian officials on board.

Windsor, Ont.—President Pressano of the Great Lakes Engineering Works, announces that he has booked contracts for the construction of four additional steel freighters, three for coast service and one for the Great Lakes trade. The steamer for lakes service will be a ship of about 9,000 tons, of 450 feet keel length, and about 56 feet beam. The three coast freighters will be of Welland Canal size.

Building Notes

Toronto, Ont.—B. C. Whitney and O. B. Sheppard have decided to rebuild the Princess Theatre.

Toronto, Ont.—The New Method Laundry will make an extension to their building to cost about $4,200

Toronto, Ont—The Toronto Hydro-Electric Commission propose erecting a large office building to cost $450,000.

Montreal, Que.—The city of Westmount will erect a municipal building to cost about $150,000. Kenneth G. Rea is the architect.

St. John, N.B.—The Rhodes Curry Co., contractors, engaged on two new warehouses on the dock, have been instructed to build a third. The latter warehouse will be 80 ft. x 350 ft.

Contracts Awarded

Galt, Ont.—The R. McDougall Co. have been awarded a contract by the city for five hydrants at $32.50 each.

Wingham, Ont.—The Canada Furniture Co. has received a large order for shell boxes, and are now making preparations to start work in the Union Factory.

Toronto, Ont.—The Board of Control have let the contract for the supply of stop valves and other apparatus for the main pumping station to Drummond McCall & Company, Toronto, at $8,530.

The Roxton Falls Manufacturing Co. has been incorporated at Ottawa with a capital of $100,000 to manufacture articles in lead, copper, iron, malleable iron and wood at Roxton Falls, Que. Incorporators: Joseph Oscar Fauteux and Joseph Adolphe Desnmarteau, of Montreal.

Chatham, Ont.—The Water Commissioners have awarded contracts for equipment for the pumping station. The contract for the pumps was let to the Canadian Allis-Chalmers Co., and the contract for the motors was given to the Canadian General Electric Co., Toronto. The pumps will have capacities of two million gallons and three million gallons respectively.

Moncton, N.B.—The contract for the steel superstructure of the new bridge over the Petitcodiac River, at this place, has been awarded by the Provincial Government to the Dominion Bridge Company of Montreal. Announcement to that effect has been made by the Provincial Board of Works, and it was said that the contract price would reach about $125,000. The sub-structure will cost approximately $200,000, making the total cost of the bridge about $325,000.

Railways—Bridges

Victoria, B.C.—The C. N. P. R. is to resume construction work on the Vancouver Island sections of the system, not only in respect to the line to Patricia Bay and that to the West Coast, but also in the matter of the de-

From Ironfounding to 4.5 in. Howitzer Shell Production

Staff Article

That the manufacture of high explosive shells can be successfully undertaken by practically any metal working enterprise when backed by an energetic and resourceful staff is here indicated. Particular note may be made of the fact that the entire plant staff of molders, core-makers, helpers, etc., has been transferred to the new industry of shell-making.

THE shell manufacturing plant which we here feature is a development arising from the transformation of part of a general iron-foundry into a machine shop, and serves to further indicate the wide variety of enterprise that has been shown in taking advantage of and meeting the munitions demand. The 4.5 in. howitzer type shell is the particular product, but as the procedure adopted is more or less similar to that practised in plants which we have previously described, a general outline only of the operations is given; the methods and devices original to the establishment are, however, dealt with in more or less detail.

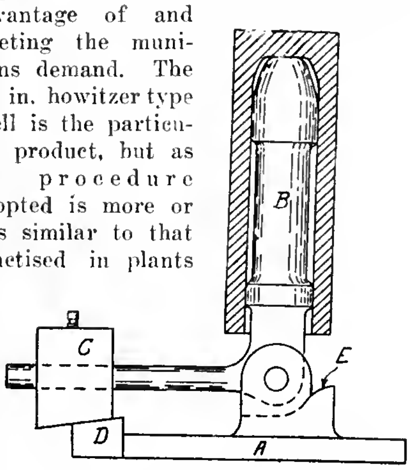

FIG. 1—CENTERING JIG

Cutting-off and Centering

Two "Hall" cutting-off machines are used for cutting the rough shells to length. These machines are placed in a shop separated from the main building. After the forgings have been trimmed to the desired length, they are taken to a drill press and the base centered.

The jig used for this operation is shown in Fig. 1. The base A is secured to the drill table in a position that brings the post B directly in line with the drill spindle. Secured to the handle of the L piece B is the adjustable block C, which acts as a balance weight and also as a gauge, as the lower surface is shaped at an angle and rests upon the beveled edge of the boss D. Alignment of the post B with the centering drill can thus be attained by adjustment of the block C. The stop E allows the post B to remain at an angle while the shells are being put in place or being removed.

Rough Turning

Rough turning is performed on three 26-inch Boye & Emmes lathes. The shells are placed between a short tapered rose arbor, which fits into the open end and the tail centre, being forced on firmly by the pressure from the tail stock spindle.

Boring

The boring operation shown in Fig. 2 is done on three 26-inch Boye & Emmes engine lathes. A special feature of this operation is the absence of turret or tool vibration. This firm, when entering the shell business, had great difficulty in obtaining the necessary machinery on reasonable delivery, and were forced to install machinery of somewhat larger range than necessary. However, this apparent objection has proved to be more of an advantage than otherwise, as greater rigidity and increased output have been the result.

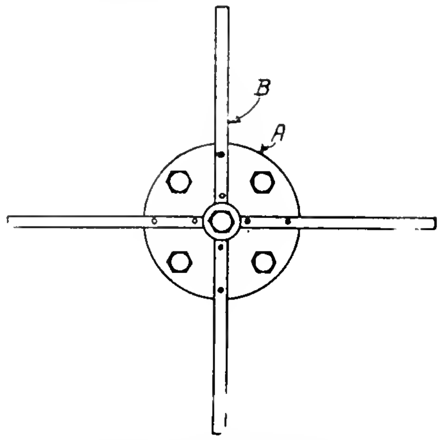

FIG. 3—SHOWING INCREASED LEVERAGE FOR HAND WHEEL

As shown in Fig. 2, special four-sided turrets are used. In the designing and the construction of these, the superintendent of the shell shop (formerly superintendent of the iron foundry) gave particular attention to the strength and stability of the device. The boring bars and cutting tools are so designed and arranged that little or no movement is observed when in operation. A small hole is drilled through the bars from the front end near the cutting tool to a location just in front of the turret face. A small piece of tubing is inserted in a hole drilled to meet the first hole, and the cutting compound is forced through this hole to the bore of the shell from the rubber tube shown.

Another noticeable feature on this operation is the absence of the customary steady head supporting the shell chuck. The increased diameter of lathe spindle and added strength renders the steady rest unnecessary. The output on these machines is, on an average, 62 shells each ten hours. An arrangement similar to Fig. 3 is secured to the traverse hand wheel on the apron to ob-

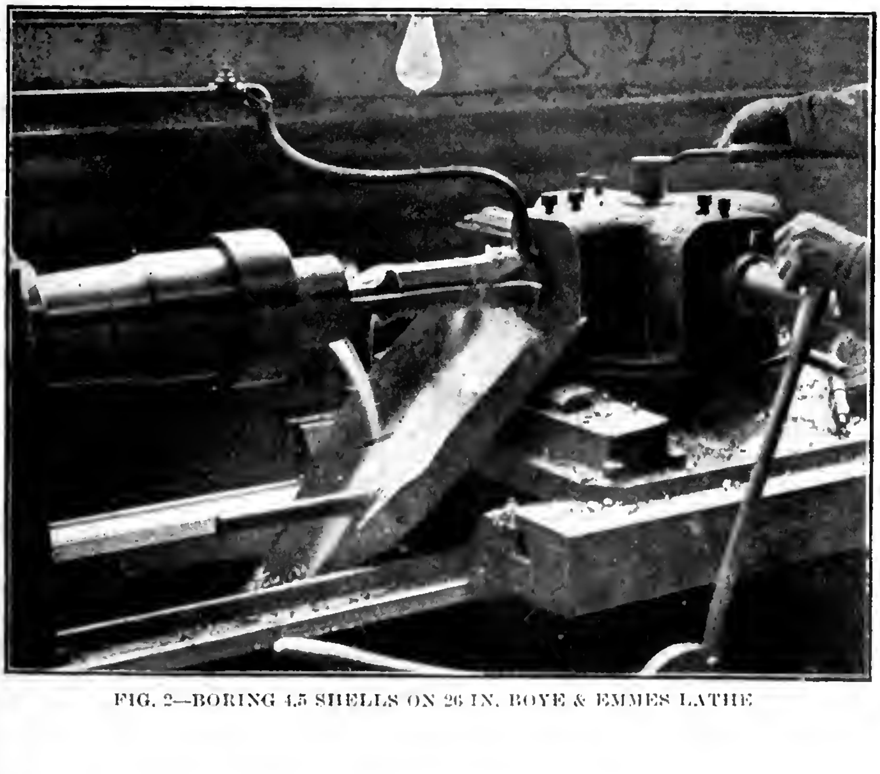

FIG. 2—BORING 4.5 SHELLS ON 26 IN. BOYE & EMMES LATHE

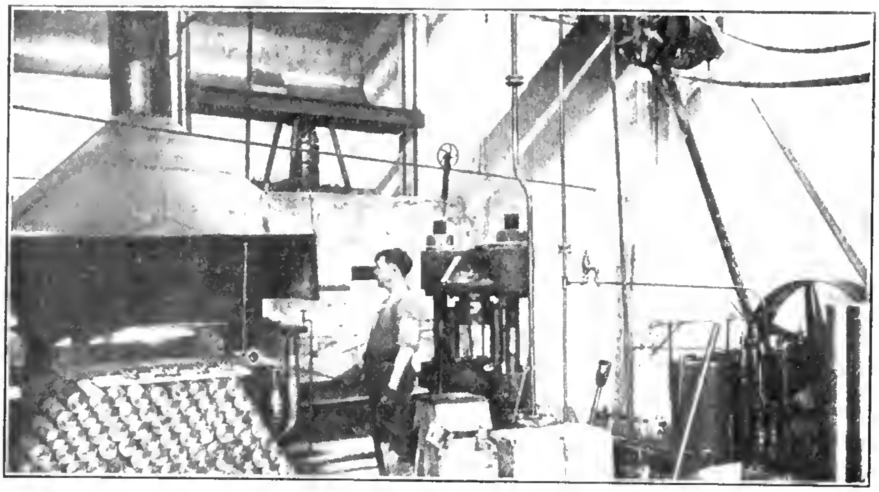

FIG. 4—NOSING EQUIPMENT FOR 4.5 IN. SHELLS

tain greater leverage to force the tool when forming the base contour.

Nosing the Shells

The nosing of the shells, which follows the boring operation, is carried out in the usual manner. The shells are placed in the Mechanical Engineering Co. furnace, shown to the left in Fig. 4. They are heated to a temperature of about 1,550 degrees F., and placed in the 150-ton Boomer & Boschert hydraulic press, which is supplied by power from the three-cylinder hydraulic pump, shown to the right of Fig. 4. The pump was built by the Canadian Boomer & Boschert Press Co., of Montreal. The nosing die is made of tool steel and encased by a water jacket. After nosing, the shells are placed in powdered lime to anneal for further machining. The furnace is also used to anneal the base discs when these through any cause are difficult to machine.

Boring and Threading Nose

Two 26-inch Boye & Emmes engine lathes are used for boring the shell nose. Special turrets have been made by the St. Lawrence Iron Foundry, Montreal, and placed on the saddle of these machines. The shell is held in a chuck similar to those described in previous articles, and the cycle of operations is boring, inside profile, face and chamfer end, recess and tap. Tapping is performed with a "Murchey" collapsing tap.

Finish Turn and Profile

The diameter and profile are finished on two Boye & Emmes 26-inch engine lathes, the operation being shown in Fig. 5. An auxiliary saddle and compound rest is placed on the lathe saddle, and two tools are employed in removing the metal, one operating on the parallel portion and the other on the profile by means of a cam and weight.

A plan of the arrangement is shown in Fig. 6. The tool E held in the tool-

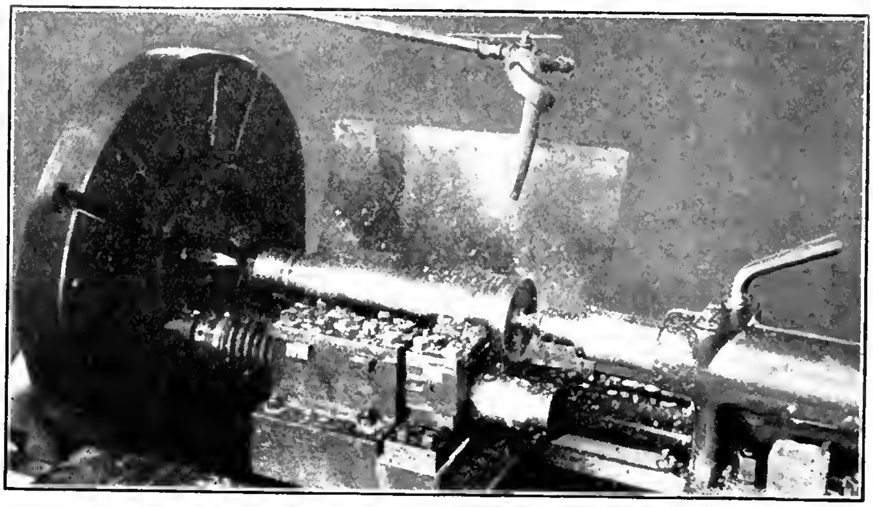

FIG. 7—GROOVING AND WAVING ON 22 IN. "McDOUGALL" LATHE

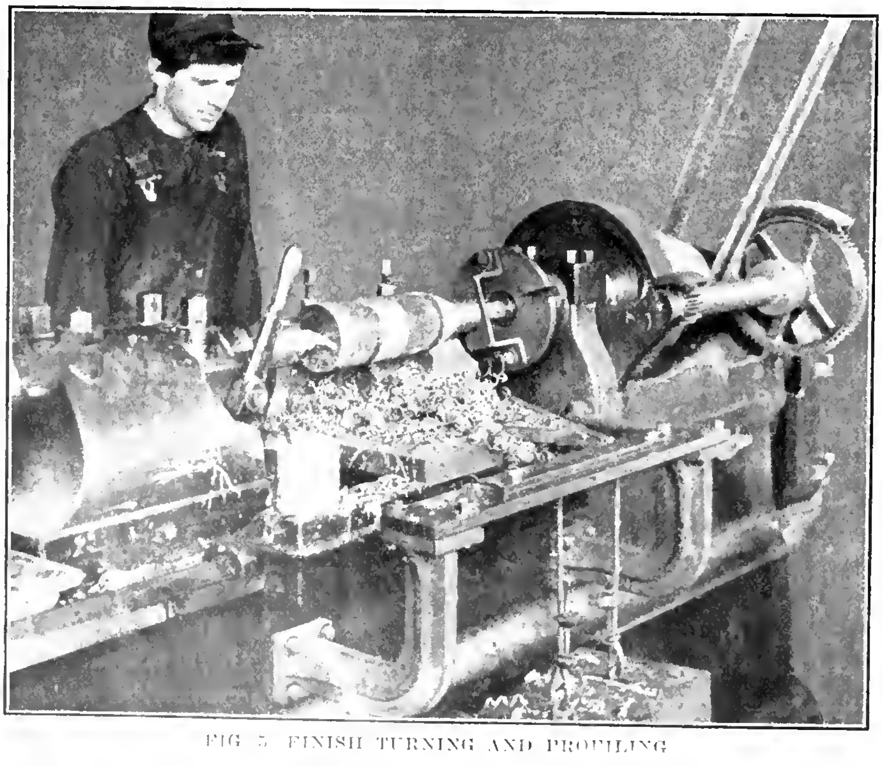

FIG. 5. FINISH TURNING AND PROFILING

post on the compound rest D, is used on the profile of the shell. Secured to the cross slide is the bracket F which carries the hardened steel piece G and is kept in contact with the cam H by means of the weight L supported by cables passing over rollers shown, and secured to studs in the side of the bracket F.

Adjustment of tool E is obtained by the movement in or out of the compound rest D. The cam H is bolted to the bar I, which is secured to the brackets J. These brackets are bolted to the lathe bed below the run of the lathe saddle. Added stability is given to the cam by the brace K, which is bolted to the bracket J at one end and the head-stock at the other.

In order that a correct profile may be produced, the cutting point of the tool E should be in line with the contact point of the piece G when a line drawn from point to point is at right angle to the axis of the shell, or lathe spindle.

The auxiliary saddle A supports the

compound rest B which carries the tool C for turning the parallel section of the shell. With this arrangement the actual traverse of the saddle necessary to complete the outside is a little over one-half the length of shell.

Obtaining the Weight

After the shells have been finish-turned, they are weighed, and the base faced off to obtain the desired weight. To calculate the required amount to face off, divide number of ounces by 72; which is the approximate weight in ounces of one inch in length of 4.5 inches in diameter.

Groove and Wave

After the base has been faced off, the shell is taken to two 22-inch R. McDougall engine lathes, where the grooving and waving is performed. This operation is shown in Fig. 7. The various operations are all completed from the front of the shell by moving the saddle to the desired position. The device here shown was designed and constructed by the St. Lawrence Iron Foundry Co., Montreal, and is showing excellent results. An average production of 100 shells is obtained on each machine every ten hours.

A sketch of the arrangement is shown in Fig. 8. The base A of the device is secured to the cross slide, and is stationary in relation to the cross slide. This piece carries the two tools C and D. The sliding piece B carries the waving tool E.

Secured in the sliding block B and passing through the piece A is the shaft F, which carries in the forked end the roller G. This roller rides on the surface of the cam H, which is bolted to the face plate of the lathe. The desired tension is obtained by the lock nuts and spring shown. The successive operating tools are set a sufficient distance in advance, so that each tool will clear the shell while the next one is working.

Shell Support

A very handy and serviceable attachment used on this and other operations is shown in Fig. 9. The piece A is secured to one of the braces B in the bed of the lathe, and supports the shell C at the required height, thus relieving to a large extent the labor otherwise necessary in handling. The full lines show an end view, and the dotted lines a side view of the support.

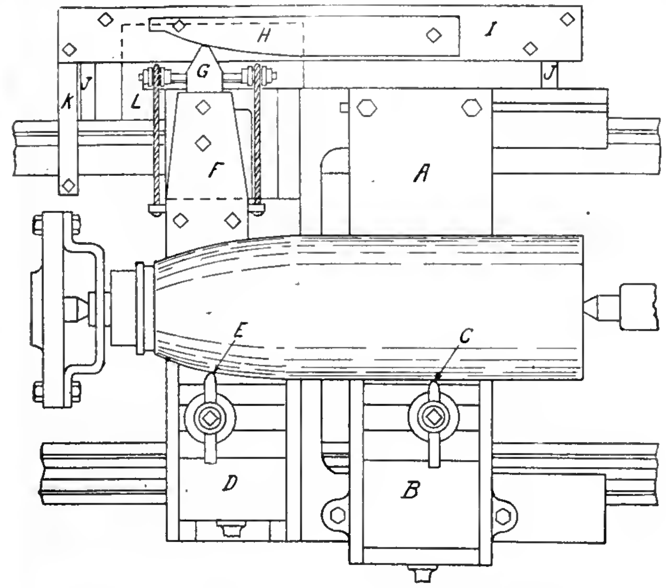

FIG. 6—PROFILE AND OUTSIDE DIAMETER FINISHING

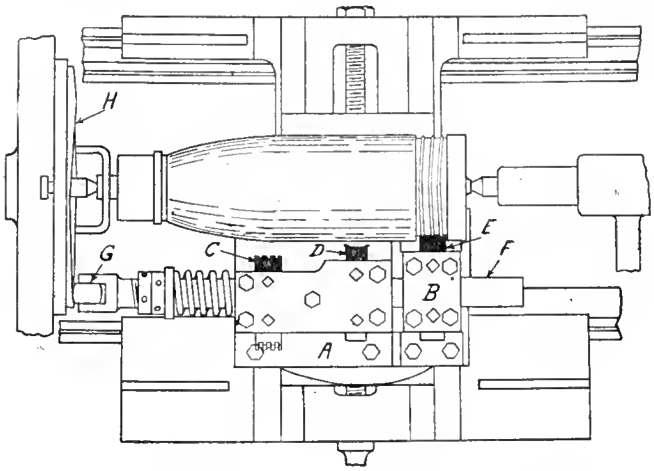

FIG. 8—GROOVING, UNDERCUTTING AND WAVING

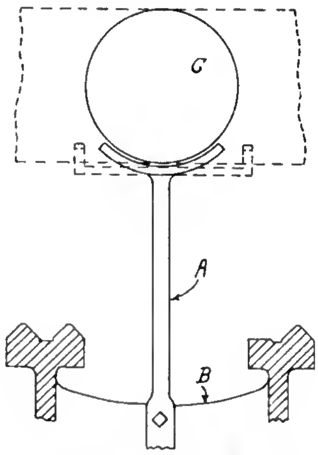

FIG. 9—SHELL SUPPORT

Base Plate Recess

The base and recess for base plate are finished in Boye & Emmes and R. McDougall 20-inch engine lathes fitted with special turrets built by the St. Lawrence Iron Foundry Co., Montreal. The base plates, instead of being threaded, are riveted in, as shown in Fig. 10. They are finished from the rough forging on an R. McDougall 20-in. lathe.

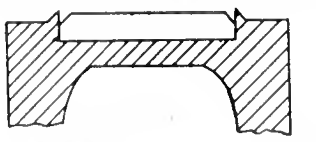

FIG. 10—ARRANGEMENT FOR RIVETING IN BASE PLUGS

The brass sockets are next screwed in and turned on 18-in. Boye & Emmes engine lathes, after which the small hole for the grub screw is drilled through the brass socket and tapped.

The copper bands are pressed on in a "Fairbanks-Morse" banding press and turned in a "Jenckes" band turning lathe.

The shells are next taken to the sandblasting room, where the bore is entirely cleaned from grease and other foreign matter in readiness for varnishing. After the varnish has been run in and out, and thoroughly drained, the shells are baked in an oven for some four or five hours.

Painting and Crating

After the baking process, the shells are taken to the painting department to receive the final touches before crating and shipping.

High Explosives.—There has been a good deal of talk in the papers lately about high explosive shells. These are of two kinds—the one with thick walls, which is almost as effective as shrapnel for man-killing under all conditions, and the thin-wall, or torpedo shell, chiefly useful for the work of destroying fortifications. These latter are dangerous to handle, as they contain a quantity of high explosive, and if they burst while being fired ruin the gun and everything around it. They are lighter than shrapnel, and, therefore, require the use of different range tables. Any reluctance of the authorities to adopt a new form of thin-walled explosive shell in the middle of a big war can be well understood. The explosive used is generally picric acid or T.N.T.

Large Shells: Production Problems and Possibilities--II.

By C. T. D.

In preparing to undertake the production of large shells up to 9.2 in. dia., manufacturers will encounter problems of a nature altogether different from those connected with 18 pdr. shells. Automatic machinery will not be so applicable to the larger sizes, and productive ability will centre largely on such points as sequence of operations, tooling methods, etc.

NEXT to having the total weight of a projectile within the specified limits, the most important requirement is that which limits the amount of eccentricity between the outer and inner surfaces. In other words, while the thickness of the walls may vary within generous limits provided the total weight is correct, it must not be assumed that these limits can be applied indiscriminately to various portions of a particular shell.

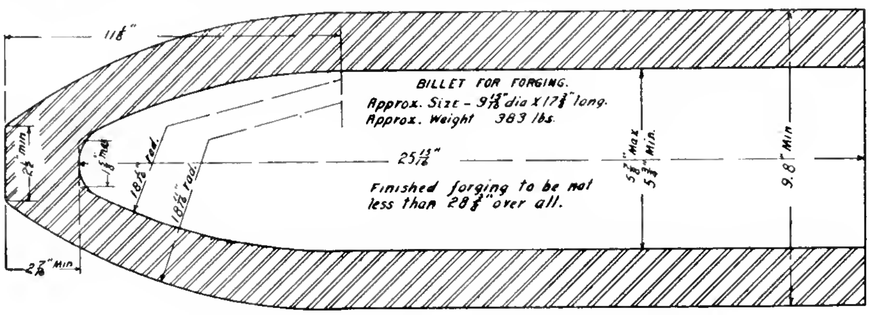

FIG. 1. FORGING SIZES FOR 9.2 IN. HOWITZER SHELL.

Such a shell might easily be out of balance to a degree which in addition to causing excessive wear on the lining of the gun, would cause its behaviour during flight to be dangerously erratic, to say nothing of nullifying its effect on enemy works. The necessity of strict limitation of this error will, therefore, be evident, and manufacturers who use every possible means to produce shells perfectly machined in this respect earn a commendation which does not materialize, but is none the less merited.

Similarity of Large Shells

The 8-in. and 9.2-in. shells differ principally in size. The methods of machining the larger shell apply equally to the smaller and the operations as outlined below are arranged with the view of using machine tools of standard types such as are already installed in plants handling products of moderate weight and dimensions. The approximate sizes of the 9.2-in. rough forging are shown in Fig. 1, the finished sizes being shown on the drawing published in the previous issue of this paper.

The number of operations included in any one group are the maximum which it is advisable to include. Where machines and men are available, operation groups may be split up, but whereas in the case of shrapnel, etc., it was possible to subdivide and simplify operations to a very large extent, thus permitting the use of unskilled labor, the mechanical skill and ability required to insure profitable and rapid production of these large shells, can be utilized to greater advantage by performing as much work at one setting as the machine is capable of. This reduces to a great extent the number of individual workers through whose hands any one shell must pass, and correspondingly reduces the possibility of loss through carelessness or lack of skill.

Factors in Production

Efficient production, therefore, is not so much a question of having a large number of different kinds of machines doing single simple operations with unskilled labor, as of having sufficient machines of fewer types, and concentrating on tool outfits which will enable skilled help to reach and maintain a large output of work which could not be handled by unskilled labor without constant risk of loss due to bad work, or breakage of machines through inattention.

The operations as outlined below are arranged in a number of groups, each of which can be handled conveniently on standard types of machines with such special tooling as individual makers may develop. Special purpose machines for one or more operations will be described in due course; at present all suggestions and descriptions refer to such methods as can be adopted with existing machines.

OPERATION TABLE.

Operation Number	Description.
	Group A.
1	Grind off scale on point, forming small flat.
2	Place on expanding arbor which locates shell from inside, and positions it lengthwise from inside of nose.
3	Face-off nose of shell to necessary thickness.
4	Drill centre with drill in tail stock, remove drill and adjust dead centre.
5	Rough turn body, commencing at nose and traveling to point where open end of shell is cut off.
6	Cut off open end of shell to length measured from nose.
	Group B.
1	Drill hole in nose, leaving stock for final boring.
2	Chuck by nose with outer end in steady. Nose of shell in contact with gauge stop on chuck.
3	Bore parallel portion with roughing and finishing cutters.
4	Form interior of nose or arch.
5	Finish overall length and counterbore. Tap base.
	Group C.
1	Tap nose.
2	Insert threaded driving plug centre in base, and common threaded plug centre in nose.
3	Finish outside to size and shape.
4	Machine and undercut groove. Wave ribs.
	Group D.
1	Press on driving band.
2	Machine driving band.
	Group E.
1	Remove service plugs and assemble base plug and nose bushing.
2	Face off base and finish bushing.
3	Enamel interior and bake.

Regarding the Operations

(Group A.) Removal of scale on the point of the forging by grinding is advisable where a rough grinding wheel is available and it should be used in preference to machining. There is no reason, however, why the point should not be cleaned off as part of operation A3, if suitable provision is made for the tool. Fig. 2 illustrates the operations referred to in group A, from which it will be seen that the use of a square tool box would allow of another tool being set up for the purpose of cleaning the nose, but the distressing effects of the scale on the cutting edge will be avoided where grinding is possible.

Trimming the open end is listed as

operation A 6. This operation is sometimes performed first or second, and where the number of machines is such that a lathe or cutting off machine can be operated continuously on this work, it may be done then instead of later, but the fact should not be overlooked that the time spent in chucking and removing from the cutting-off machine is a straight addition to the total time on the shell. By performing operation A 6 on the same machine as the other A opera-

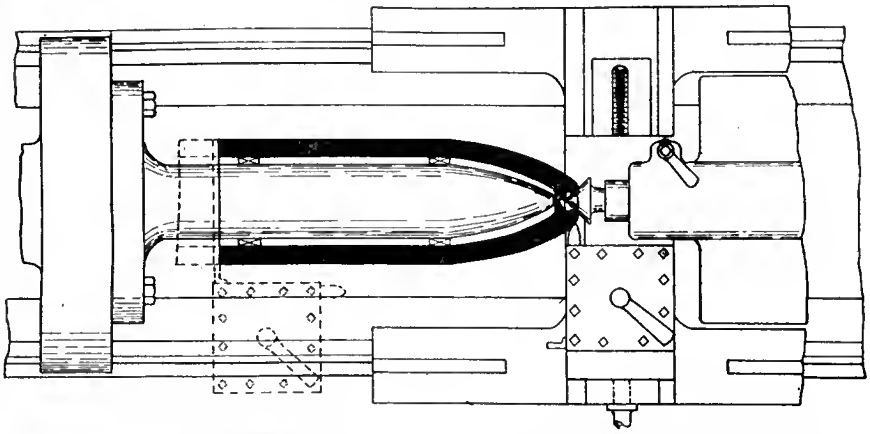

FIG. 2. ROUGH TURNING AND CUTTING OFF ON REGULAR ENGINE LATHE.

tions, the time of this extra handling is saved.

Proceeding now to A 2, a lathe of ample power is necessary, as the roughing must be done in one cut if satisfactory progress is to be made. All of the power and stiffness available in a 30-in. lathe with 6-in. belt is none too much for the continuous strain of pulling a heavy cut on projectile steel.

The design of expanding arbor should

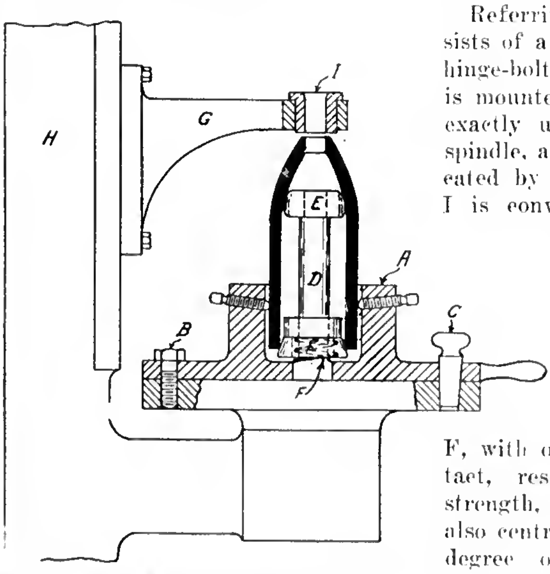

FIG. 3. FIXTURE FOR CENTERING AND DRILLING SHELL FORGINGS IN DRILL PRESS

be such that all possible strength is obtained at the root of the stem where it spreads out into the driving flange. Numerous types of expanding mechanism have been devised for arbors handling the smaller sizes of shells and modifications of these can be adopted if ample power be provided for expanding the driving dogs.

The nose of the shell is now faced off to a specified distance after which the centre is drilled in the conventional manner, and the dead centre adjusted, when the operation of rough-turning the outside may be proceeded with.

An alternative method of procedure up to this point, and one which will appeal to the small producer, is to centre the shell in a drill press and then chuck it by the untrimmed base in an ordinary four-jaw independent chuck, supporting the outer end in the tail-stock. After rough turning, the shell would be cut off close to the chuck. A suitable centering fixture is shown in Fig. 3. If preferred, the nose may be drilled out to approximate size and a pipe centre used afterward in the lathe.

Referring to Fig. 3, the fixture consists of a plate A, which swings around hinge-bolt B. A vertical stem or arbor B is mounted on the plate so as to pass exactly under the centre of the drill spindle, and when in this position is located by taper pin C. A drill bushing I is conveniently supported from the column of the machine. The upper end of the arbor is provided with a three-cornered flange E, which centres the forging from the inside, while a similar method is adopted at the lower end where a tapered plug, F, with or without three-point contact, rests on a spring of suitable strength, so that the base of the shell is also centred from the inside with a fair degree of accuracy. Set-screws, as shown, hold the shell firmly while being drilled.

The shell is now transferred to the engine lathe where an arbor of similar type is employed. The point of the arbor projects right up to the end of the nose where it has three-point contact on a circle slightly larger than the hole. The back end of the arbor has a spring controlled taper plug for centering from the inside. With the tailstock centre pressing the forging against the point of the arbor, and the open end centred by the spring plug, the chuck jaws are tightened up carefully around the base, when operations proceed as before. When this method of driving is adopted, it may be found preferable to face the nose down to thickness by means of a short cutter-bar used in the tail-stock and having a pilot to neutralize the long overhang of the shell from the chuck.

Assuming that up to this point a satisfactory sequence of operations has been decided on, the shell is now ready for rough turning.

Chief interest in this operation centres around the method of forming the profile. The radius link method is simple to construct and operate, but calls for close duplication in placing the forgings, and considerable accuracy in locating the point at which it is disengaged and a parallel cut started. A plan view, Fig. 4, shows the principal features of this method.

Secured to the cross-slide A is the stud B. Upon this stud is placed one end of the link C, the opposite end of which is placed over the stud E, which is held in the bracket D. This bracket is firmly bolted to the bed of the lathe, the stud E protruding above the level of the saddle.

The tool rest, and cross-slide as well as the stud B will travel as a unit; therefore the path of the cutting point of the tool will be an arc of a circle, whose radius will equal the length of the link C. Care should be taken to have the

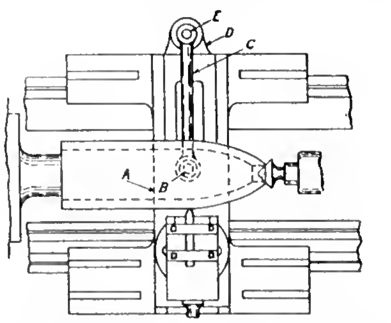

FIG. 4. METHOD OF USING LINK FOR FORMING PROFILE ON SHELL.

cutting tool in the proper position when the link C is at right angle to the axis of the shell or lathe spindle.

The length of the link, between centres, for the 8-in. shells would be 15.9 inches, and for the 9.2-in. shell would be 18.4 inches. The desired size is obtained by the use of the compound rest. It might be well to state that no matter in what position the tool is, the radius of the contour will always be the same when the same link is used.

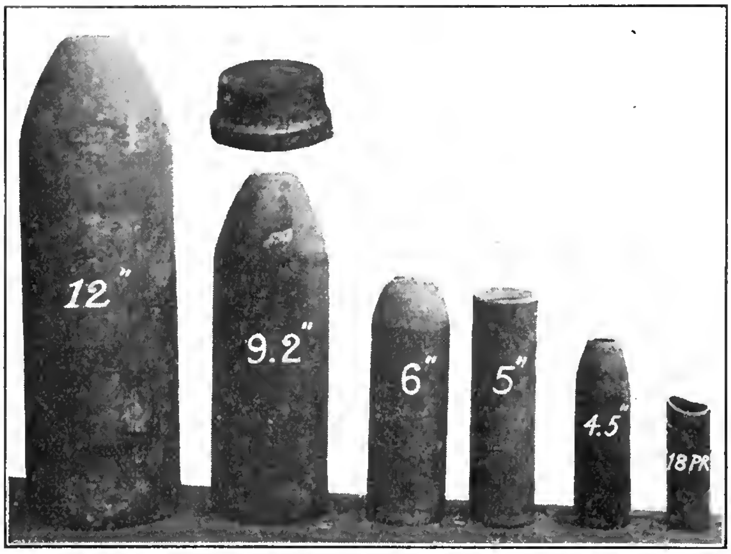
The method of forming the profile

from a copy bar either at back or front of the carriage has attained a fair degree of popularity and will doubtless be adopted by several makers. Once it is adjusted for position, it requires little attention to operate.

The necessity for accuracy in machining the thickness of the nose now becomes apparent. While the outside diameter of the parallel body can be easily measured by gauges, and the approximate thickness of wall readily determined, the same method cannot be used on the nose profile. Assuming, therefore, that the nose has been faced so as to leave a safe thickness of metal, the extent to which the outside can be machined can be determined from the reduced diameter of the flat end of the nose.

If, when the parallel portion is roughed to size, the diameter of the point of the nose is still large, the cutting tool must be moved to the left, but not any nearer the centre. The effect of this is to take another cut from the outside of the nose, but no more from the diameter of the body. The actual dimensions of nose thickness and diameter of the face when rough turned require, therefore, to be carefully determined at the start, after which suitable profile gauges will enable rapid production to be maintained.

The rough cut is carried down to the base till enough machined surface is obtained. Should the base have been cut off in the first place, no further work will be required under group A, but if not, the point for cutting off the base can be accurately located from the point of the nose, after which the shell is ready to proceed to the operations outlined in group B.



GROUP OF SHELL FORGINGS.

LITTLE KNOWN FACTS ABOUT GRINDING—BELTING

By H. W. Dunbar.

HOW many operators or owners of grinding machines fully realize the important part the belting plays in the actual production and quality of the work accomplished in a grinding machine? I think very few. This statement is based on observations made while passing through shops using a great many grinding machines.

The Finish Feature

To begin with, when one desires to finish work having a true, high-reflecting surface, free from chatters and mottles, the belts must be absolutely true when running, and must have a uniform thickness throughout their entire length. The slightest variation in thickness either where an endless belt is joined together or where a lacing of wire, rawhide or other material is used, will immediately set up a vibration in the parts with which this belt is connected. These vibrations, if of great enough magnitude, will be transmitted to the wheel or the work, and the result will be chatters or mottles. This applies, of course, primarily to those belts in close proximity with the wheel and work, such as the belt running from the motor to the frame drum on the back of the slide, or from the drum to the wheel spindle, or from the headstock (if it be a belt driven machine) to the drum overhead. When one desires a finish of such a degree of perfection, the belts must be as smooth in their running as it is possible or practicable to make them.

The trouble generally comes when the original belts, which have not only to be true for thickness but run true as well, have been worn out and have to be replaced. It is then that great care must be taken to see that a good quality belt, perfectly true, be selected to replace the old one. To maintain this condition indefinitely throughout the life of the belt it becomes necessary to select the very best grade and quality of belting for a grinding machine. Never replace an endless belt with one carrying a wire lacing or any other form of lacing which will give a "bump" as it passes over the pulley: if you do you cannot get smooth work. So much for finishing.

The Production Feature

On the question of production, it is well known to the designers of grinding machines that uniform speed of the wheel and uniform revolution of the work are essential to the greatest efficiency of the machine. If for any reason the wheel slows up while performing work, the cutting action immediately changes and production falls off; the same is true of the work if it varies in speed. The relative speed of the wheel to the work, when the correct speed has once been selected, must be maintained constant. This affects not only the production of the parts being ground, but also the wheel wear.

From this it will be seen that it is necessary that the belts be of the proper width to transmit the power necessary to do the work. They must also be maintained at a constant, uniform tension, which will also insure a constant speed.

Care must be taken to prevent oil and grease from getting on the belts to aid in maintaining this condition. Do not fill the spindle boxes so full of oil that they run over and drop on to the belts. Learn how much oil must be put into each place, and keep the oil level, so adjusted as not to waste the oil and bring about unsatisfactory results through its being distributed over the belts. It will be seen that poor belting will stretch in spots and not allow the belt to have a uniform friction on the surface of the driving pulley, resulting in loss of speed.

As a last word of caution, keep the belts smooth; keep them true; and always replace the original belts with others of the same grade, quality, thickness and width. Keep them free from oil and foreign substances.—Grits and Grinds.

MAIL TO SOLDIERS

IN order to facilitate the handling of mail at the front and to insure prompt delivery it is requested that all mail be addressed as follows:—

(a) Regimental number.

(b) Rank.

(c) Name.

(d) Squadron, Battery, or Company.

(e) Battalion, Regiment (or other unit), Staff appointment or department.

(f) Canadian contingent.

(g) British Expeditionary Force.

(h) Army Post Office, London, Eng.

Unnecessary mention of higher formations, such as brigades and divisions, causes delay.

Sheet Metal Elbows: Their Development and Laying Off-IV

By J. W. Ross

In order to thoroughly understand the principles involved in the development of cylindrical and other forms, such as are met in sheet metal work, a considerable knowledge of geometry is desirable. Through the medium of these articles, the author places practical examples at the disposal of our readers, and the knowledge to be gained by a close and persistent study of the principles and methods employed will well repay the time spent.

180-DEGREE ELBOW

FIG. 18 shows the elevation and cross-section of a 7-piece U-shaped elbow of 180 degrees plated with inner and outer courses.

Mark off the inside diameter, CD, $23\frac{1}{2}$ inches, and the outside $24\frac{1}{2}$ inches, thus making the neutral diameter 24 inches. Measure off D to O equal to 21 inches. With O as centre and the inside diameter at C as radius, strike the arc CC^1. Again with O as centre and the inside diameter at D as radius strike the semicircle DD^1. Divide the semicircle CC^1 into 12 equal parts. As the elbow is made up of seven courses, each part will then be equal to 180 degrees $\div$ 12 equal to 15 degrees. At the points located draw in the radial lines as AO, LO, NO, PO, JO, KO. Draw in plate thickness from C and D to the mitre line AB, and at right angles to the line CDO. Draw in the thicknesses LN and L^1N^1 of the course J with the inside diameter tangent to the two semicircles CC^1, DD^1, respectively. This may also be done by using O as centre and the thicknesses A and B as radii (course R), marking these distances off on the radial lines from O as centre, and locating the thicknesses at LNPJK, also $L^1N^1P^1GM$. Connect these points by lines representing the plate thickness for the inner courses, also draw in the outer courses as shown in Fig. 18.

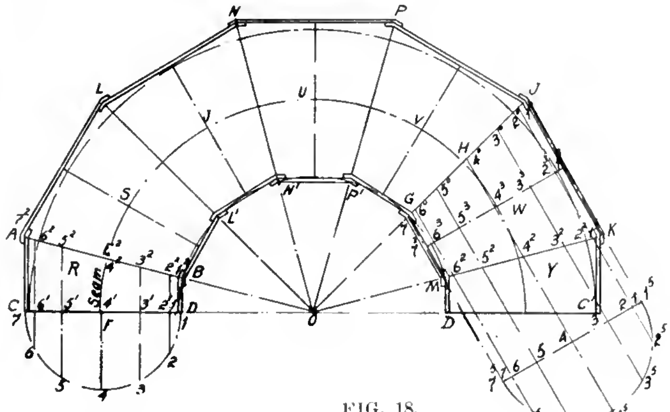


FIG. 18.

With centre 4^1 and the neutral point 7 as radius, draw in the half section plan view 741. Divide this into a number of equal parts. From these points draw in the construction lines—through and at right angles to CD—to the mitre line AB. Number as specified.

Calculate the stretchout of the neutral diameter 7 1, which is 24 × 3.14 equals 75.36, or nearly $75\frac{3}{8}$ inches. Measure off this distance along the line FCDF, Fig. 19. Divide this into twice the number of equal parts as in 7 4 1, Fig. 18. Raise perpendiculars from these points and number accordingly. Transfer all the distances from course R in a similar manner as explained in previous problems. Fig. 19 shows the whole pattern for R and Y courses, and the half pattern for courses J and V.

The courses S, U, and W are outside courses and require to be developed as such. For sake of clearness the centre girth line 7^31^3 of course W is projected to 7^51^5. Centre line HL is extended to 4 4^5; with 4 as centre and the neutral radius of course W, which is 4^57^5, draw in the neutral half-section plan view of course W, as $7^54^51^5$. Divide this semi-circle into an equal number of parts. From these points draw lines parallel to JK and $HI4^5$, to their intersections on JHG. Number these lines as shown, and then calculate the stretchout. The inner course is $75\frac{3}{8}$ ins.; an easy fit is desired for the outer course, therefore to this measurement add on $6\frac{1}{2}$ times the plate thickness. The stretchout for the outer course will equal $75\frac{3}{8} + (6\frac{1}{2} \times \frac{1}{2}) = 78\frac{5}{8}$ inches. Measure this distance off along the line $4^34^34^3$, Fig. 20. Divide into twice the number of equal parts as are used in the half section view 7 4 1, Fig. 18. Draw perpendiculars through these points. Number as shown, so that the longitudinal seam will be located at HL, Fig. 18, when the course is rolled up.

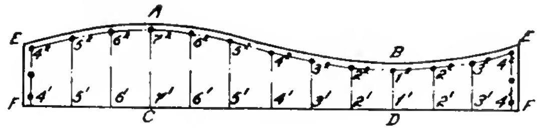

FIG. 19.

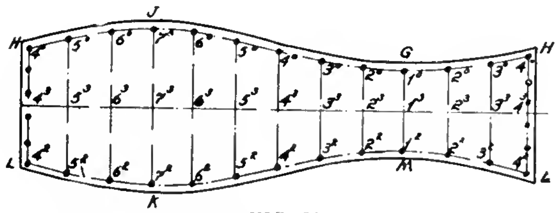

FIG. 20.

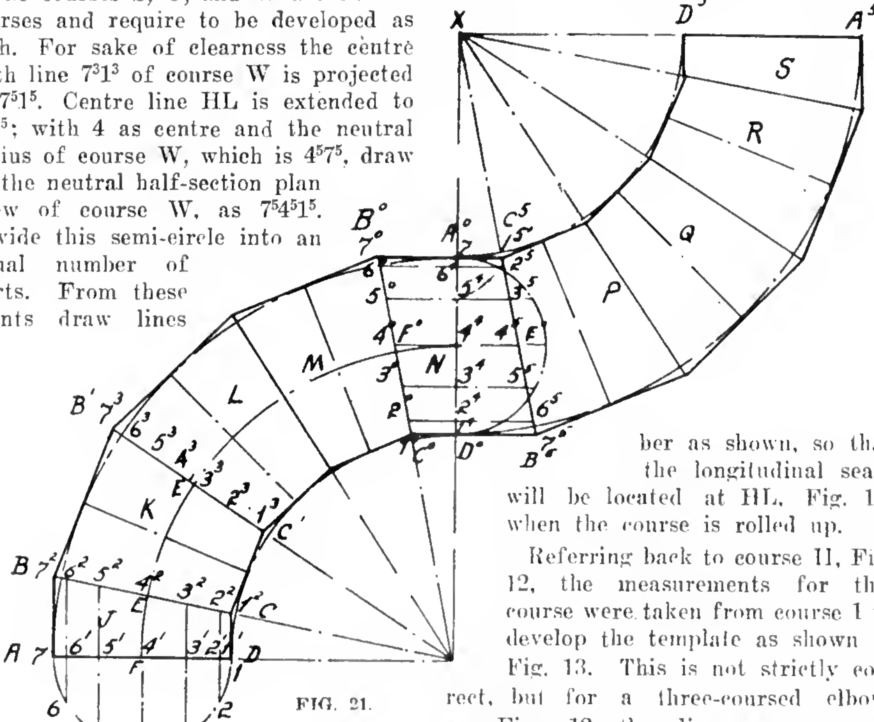

FIG. 21.

Referring back to course II, Fig. 12, the measurements for this course were taken from course 1 to develop the template as shown in Fig. 13. This is not strictly correct, but for a three-coursed elbow, as Fig. 12, the discrepancy would be immaterial, as this only comes in the one course. In an elbow of several courses this difference would be propor-

tionate to the number of courses and the thickness of plate used.

It will be noticed in Fig. 12 that the distance BC is slightly longer than AB and that JH is shorter than JK. This appreciable difference coming in each of the three courses, S, V, W, would not be conducive to accuracy. With this defect pointed out, the template, Fig. 20, will be developed from the construction lines on course W, Fig. 18, which are drawn in for this purpose.

With dividers set to the distances $7^3 7^0 6^3 6^0$, etc., Fig. 18, transfer over to $7^3 7^0$, $7^3 7^2$, $6^3 6^0$, $6^3 6^2$, Fig. 20, similar to the preceding problems. Fig. 20 shows

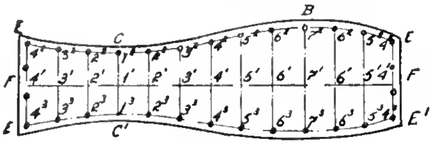

FIG. 22.

the complete template with lags added and rivet holes marked in. It is again repeated that it is not necessary to draw in the full elevation view as shown in Fig. 18, unless desired. All the necessary information can be obtained by calculating the mitre line and on this drawing in the construction lines as shown by course R, and the construction lines of course W, drawn on course S. Therefore all that need be drawn will be courses R and S.

Double Elbow

Fig. 21 shows a double elbow of 9 courses. It is drawn out in full elevation to illustrate the method of obtaining the development of course N.

Measure off AD 18 inches, and OD 22 inches. With centre O and radii OA and OD strike the quadrants AA^0 and DD^0. Draw A^0D^0O at right angles to ADO. With radius OA, mark off the point X on the extended line OD^0A^0X, from the point D^0. With the same radius and X as centre, draw the quadrant D^0A^5; also

FIG. 23.

with X as centre and XA^0 as radius draw in the quadrant A^0D^5. XD^5A^5 is parallel to ADO and at right angles to XA^0D^0O. Divide the quadrants AA^0, D^0A^5 each into 8 equal parts and connect these points to their respective radial points O and X. Draw in the outline of the pipe similar to preceding problems. Fig. 22 shows the whole templet for courses KLMPQR, and half of this templet will be the pattern for courses J and S.

Course N will now be developed. On neutral diameter A^0D^0 strike the half-section view $A^0E^5D^0$. Divide this into the same number of parts as course J. Draw construction lines from these points parallel to B^0C^5 and C^0B^5. Number as shown. The stretchout of the diameter A^0D^0 is equal to the stretchout of the diameter AD, course J, which is 18×3.14 equals $56\frac{1}{2}$ inches. Measure off A^04^4,D^0, Fig. 23, equal to $56\frac{1}{2}$ inches and divide this line into 12 equal spaces, which is twice the number in the half sectional view $A^0E^5D^0$, Fig. 21. Draw perpendiculars through these points. With the longitudinal seam on 4^04^5, Fig. 21, number accordingly on Fig. 23. With dividers set to 4^44^0, Fig. 21, transfer over to Fig. 23 as 4^44^0; reset the dividers to 4^44^5, Fig. 21, and transfer over to 4^44^5. Fig. 23. Similarly transfer all the rest of the measurements over to Fig. 23. The complete templet is shown in Fig. 23 with rivet line in rivet centres and lap allowances drawn in.

SAFETY IN CRANE CHAINS

By E. B. Morgan

AFTER quite an extended study of failures due to a crystallized link, the writer has concluded that they are due to imposed stresses equal to and in excess of the elastic limit, and in this brief discussion will attempt to show that the crystallized link is undoubtedly due to overloading and cannot be prevented by annealing.

The term crystallization is undoubtedly a misnomer, as all steel and iron is originally crystalline in structure. What really takes place is that the working of the metal beyond the elastic limit simply breaks down the long fibers or granulates them. It is simply a condition of fatigue. The characteristic hardening or brittleness of the metal in this condition is undoubtedly due to the heat which is set up internally by the slippage of the fibers.

Determing the Safe Load

The writer is firmly convinced that the proper safe load should be based upon a permissible working stress for the extreme fiber, and not on the ultimate breaking strength test of the chain. This necessitates the solution of the maximum extreme fiber stress developed in an elliptical shape which is the usual shape of a chain link, and involves a theory which has received very meager attention in technical works. There seems to have been only one attempt to develop a formula for the fiber stress developed in an elliptical ring based on experiment and good sound theory. I refer to a thesis on the strength of chain links made at University of Illinois Experimental Station in 1907, in which the following formula has been developed for open links. This formula can be readily derived by applying the theory of flexure in curved shapes.

$$f = \frac{P}{0.4d^2}$$

Where f = extreme fiber stress in tension.

d = diameter of the stock used in link.

P = load on the chain.

In a recent bulletin on safe loads issued by the National Safety Council, the subjoined safe loads for straight suspension for wrought iron hand-made short link chain are recommended. The writer has found by actual experimental tests that these values are on an average of about one-seventh of the ultimate breaking strength, and are in fact a trifle lower than the loads imposed in general practice in most plants.

Size	Safe load
½ in	2,400 lb.
⅝ in	4,000 lb.
¾ in.	5,500 lb.
⅞ in.	7,500 lb.
1 in.	9,500 lb.

With these recommended safe loads the following stresses in the extreme fiber are developed by using the formula as cited above.

½ in.	24,000 lb. per sq. in.
⅝ in.	25,600 lb. per sq. in.
¾ in.	24,500 lb. per sq. in.
⅞ in.	25,000 lb. per sq. in.
1 in.	23,700 lb. per sq. in.

This means that the extreme fiber will be stressed up to and in excess of the elastic limit in the case of an iron chain, as the writer has made repeated tensile tests on Norway or Swedish iron, which is about as pure as any commercial iron obtainable, and has never developed more than an average ultimate tensile strength of 44,000 lb. per square inch, and an average elastic limit (or drop of the beam) of 23,500 lb. per square inch.

This shows how such loading as exhibited produces stresses in excess of the elastic limit, notwithstanding the fact that the impact stresses due to mechanical braking when lowering the hoisted load, which are no doubt very severe under certain conditions, have been neglected. It is evident this magnifies the danger in applying stresses which will destroy the resiliency of the metal. This is, without a doubt, the reason why chain links become brittle and fail. It is also the reason why the average user encountering such difficulties resorts to annealing as a remedy.

The Annealing Question

There has been much said of late both pro and con concerning the annealing of chains for restoring the metal from the so-called crystallized condition to the original physical properties. No doubt this annealing is a good thing in that it often forestalls failure, not because the

metal has been completely restored to its original qualities, but because it has simply been made tougher. The writer has made several experiments on sections of metal taken from crystallized links, trying to find out whether annealing really does completely restore the metal. A series of four tests was made in each of the following cases:

A test bar was prepared from a piece of original stock of Norway iron, which was used in making up several chains. These chains were put in service and subjected to loading in accordance with the tables recommended in handbooks, and after a short time became fatigued and failed. Two test bars were prepared from each side of the failed link, one bar being left in the fatigued condition and the other annealed to a temperature of 1,500 deg. F. These specimens were tested in a tensile machine with the following results. The figures exhibited are an average of four tests in each case.

observed to procure maximum safe conditions in crane chain practice:

1.—Decide upon material desired, low-carbon open-hearth steel or an iron as nearly free from impurities as possible. A pure iron, I believe, is preferable to steel as it makes a better weld than steel, and also an iron link will stretch out to a lock more easily if overloaded, which serves as a telltale for inspection.

2.—Prepare a rigid set of specifications covering the material, workmanship, and tests desired.

3.—Insist on a hand-made link, as the machine made link is bent cold around less than twice its own diameter at a high speed on an elliptical mandrel. This sets up severe initial internal stresses in tension and compression in the outer and inner fiber of the link respectively. The hand-made link is made under a cherry red heat and obviates such stresses; also a far better lap weld is secured in a hand-made link.

Specimen	Elastic Limit (Drop of Beam)	Ultimate Tensile Strength	Per Cent. Elongation	Reduction of Area	Fracture
Original stock	25,600	41,500	48.5	78.4	Cup
Fatigued, not annealed	38,700	46,900	29.0	74.6	Irregular
Fatigued, annealed..	30,000	44,300	47.0	78.3	¾ cup

The chemical analysis of the original stock showed carbon, trace; phosphorus, 0.029 per cent.; sulphur, 0.006 per cent.; manganese, trace; silicon, trace.

A careful examination of the above test data will show that the annealing did not completely restore the original physical qualities of the iron. The writer does not feel that annealing is inadvisable, but is firmly convinced that annealing is not the cure for fatigue. Annealing chains is certainly a good additional safety factor in that it softens the metal and does away with the dangers of a brittle link, but the fact still remains that an annealed chain will undoubtedly fatigue if overloaded, so we are not going to have maximum safety in chain practice by all the proper annealing.

What must be done is to revise the present code of so-called safe loads and base them on the rational basis of the permissible extreme fiber stress of the material used. It is going to be hard to remedy this overloading of chains, as a big misunderstanding has taken deep hold of the average mechanic and user of chains. To convince an old shop hand that a ⅝-in. iron chain should be only worked to 1,600 lb. in straight tension when he has been using it to about 5,000 lb. is indeed a hard proposition, as he feels it is perfectly safe because the chain has carried the load numerous times without failure.

Recommendations

In summarizing the writer feels that the following points should be closely

4.—Number each chain and keep a record of when it goes into service and length of service and class of work it is used for. Inspection should be made daily by a competent and experienced person to detect any reduction of section due to wear, deformation of links and any visible flaws developed in the welds. This is somewhat tedious and expensive, but must be done and done carefully to insure safe operation. A fatigued link has a characteristic metallic ring when struck a sharp blow with a hammer, while a good piece of Norway iron has a decided dull sound when so struck. The writer has found that rings so detected by a metallic ring can be further tested by placing the link edgewise on an anvil and striking it several sharp blows with a sledge. If it is fatigued it will break with a decided crystalline fracture.

5.—Special attention should be given to the design of the ring that connects the chain to the block hook. This ring should be designed to withstand the same load as the chain, using the regular formula for a circular ring under tension in a diametral line.

6.—It is advisable to check up the size of the hook as the writer has found the usual practice of designing a hook is to use the following empirical formula:

$$f = \frac{P}{A} + \frac{Px}{S}$$

Where S = area of critical section S S

This formula is in error in that the second term represents the bending stress calculated from the formula used for straight beams, which, however, does not apply to curved pieces, and the formula given above is not even approximately correct. The correct stress caused by the bending moment can be solved by consulting any standard work on strength of material. The writer has also found many operations where it is necessary to suspend the load on the point of the hook. If there is any possibility of such practice, the hook should be designed accordingly, otherwise the stresses produced will be dangerous.

7.—The last but most important recommendation is:—To subject the chains to a proper load and as an additional safety precaution, anneal them before they are put in service. This annealing though will not prevent fatigue of the metal in case the chains are overloaded, but will merely soften the chains so they will pull to a lock and serve as a telltale for overloading.

It is obvious from the foregoing discussion on the causes of fatigue that annealing at regular intervals is entirely unnecessary, as, if there is any benefit from annealing at all, it will be merely to toughen the metal, and therefore is only necessary once.

From a paper before the National Safety Council Congress at Philadelphia, by E. B. Morgan, safety engineer, Commonwealth Steel Co., St. Louis.

NOVA SCOTIA STEEL CO.

AT a meeting of the directors of the Nova Scotia Steel & Coal Co. at Halifax, N.S., on Nov. 11, the general manager reported that in October the shipments exceeded those of September by 30 per cent., and that unfilled orders on November 1 and material since actually booked would call for 180,000 tons of steel. This is quite apart from the car-building material requirements which are likely to be large. Estimates for the construction of a new open hearth and steel-melting furnace of the largest type were submitted. The management were directed to proceed with construction at once. The new furnace will be ready to produce two hundred tons of steel per day within twelve weeks. Foundation work for the new forging plant is now well advanced.

R. E. Chambers, superintendent of mines, was instructed to resume the underground mining of ore at Wabana immediately, and to continue work throughout the winter at maximum capacity. The export of forged shell blanks is increasing weekly, and further new business for foreign account has been offered the company during the present week. The Eastern Car Company despatched three steamers with cars this week.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

NEW SHELL BORING LATHE

BEING a matter of vital importance that the output of machine tools for the production of shells should be increased to the maximum, Alfred Herbert, Ltd., Coventry, England, have put in hand large batches of a simple design of turret lathe for shell boring, from which all unnecessary work has been eliminated, and which it is, therefore, possible to build very rapidly. The No. 5 Shell Boring Lathe, as it is called, embodies, nevertheless, a number of valuable features, all of which tend towards high production; the line drawing, Fig. 1, gives a good idea of its general appearance.

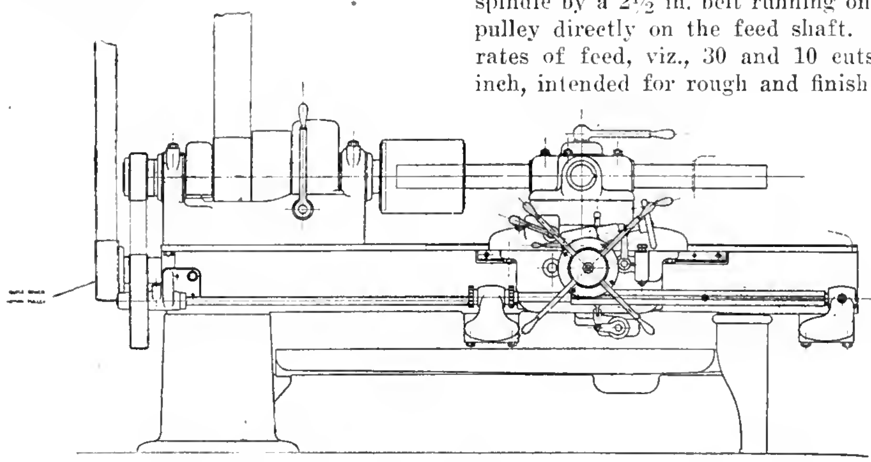

FIG. 1. OUTLINE DRAWING OF NO. 5 SHELL BORING LATHE.

The machine has been designed chiefly for performing the boring and bottoming operations on high explosive shells from 4.5 in. to 6 in. inclusive, but with a suitable tool arrangement it can be used for a number of other operations, such as boring the chamber for the base plug, and forming and facing the closed end of high explosive shells, and also for boring shrapnel shells.

The headstock, which has a height of centres of 10 in., has a large spindle with a 10-in. flange. It has a two-step cone for 5½-in. belt and back gearing of a high ratio. The cone pulley does not drive the spindle direct, but only through the gearing, the spindle being started and stopped by a friction clutch in the main gear, operated by the lever in front of the headstock.

The cone pulley is intended to be driven from a cone formed by putting two split pulleys together on the lineshaft. When used on shell work the lathe is run continually on one spindle speed. The second step of the cone makes it possible to obtain an additional speed by shifting the belt. This is an advantage if an occasional hard forging is met with, and it becomes necessary to slow down the speed.

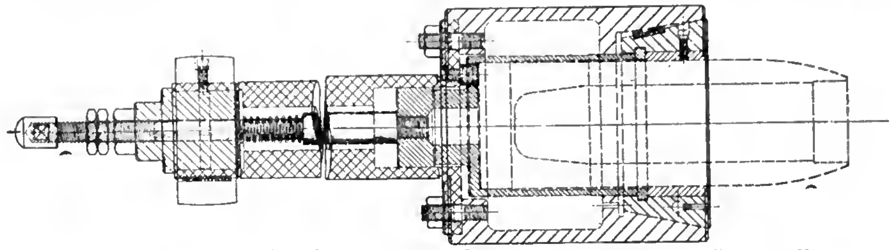

FIG. 2. DRAW-BACK CHUCK FITTED TO NO. 5 SHELL BORING LATHE.

The feed motion is driven from the spindle by a 2½ in. belt running on to a pulley directly on the feed shaft. Two rates of feed, viz., 30 and 10 cuts per inch, intended for rough and finish boring respectively, are obtained by a gear change in the apron.

The turret has four tool holes 3¼ in. diameter, which are provided with keyways. It is rotated by hand and clamped to its seat after indexing by a powerful hand lever. Provision is made for keeping the indexing plunger disengaged, so that the turret may be used with former-controlled bars, if required.

The turret slide has quick power traverse motion along the bed, which is of great service, particularly where female labor is employed. Automatic and dead stops are provided for each hole in the turret, the rotating stop rod being in front of the bed. It has the patent "unison" motion, which allows all the stops to be moved endwise to accommodate variations in the forgings. In addition to the pilot wheel there is a powerful hand feed to the turret by worm gearing for finishing the bottom of the shell bore. An oil pump and piping are included, giving an internal supply to the tools.

A plain reversing countershaft can be furnished as an extra when boring and tapping of shell noses after "bottling" is to be done. As closed-in shells are now being replaced by the "block filled" type with screwed in noses, this extra will hardly ever be required.

The Chuck Feature

The chuck being supplied in conjunction with this machine is shown in the line drawing, Fig. 2, and is of the drawback type. This chuck was designed with a view to making it suitable for employment with female labor.

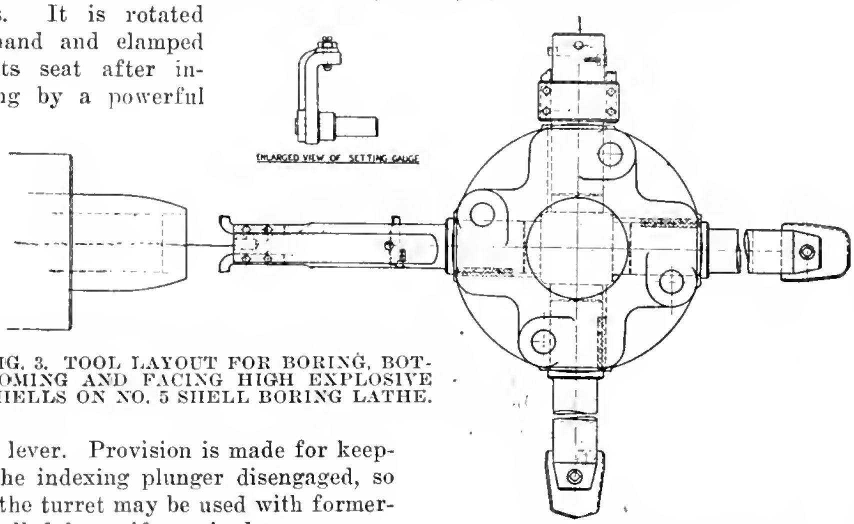

FIG. 3. TOOL LAYOUT FOR BORING, BOTTOMING AND FACING HIGH EXPLOSIVE SHELLS ON NO. 5 SHELL BORING LATHE.

Referring to the line drawing, it will be seen that the body of the chuck is an

iron casting bolted on to the spindle flange, the front end being bored taper to receive the split collet; this is furnished with steel liners, which can be renewed when worn. The collet is pulled back by a steel sleeve which has a collar on the front end fitting in an annular groove in the collet. The back end of this sleeve is bored to fit the closed end of the shell which butts back against a fixed stop screwed into the spindle flange. The location is, therefore, unaffected by variations in the diameter of the shell.

The draw-back rod itself is operated by a hexagon nut at the back end of the spindle, an ordinary spanner being employed for tightening the chuck. The following advantages are claimed for the chuck:—

It holds the work securely under the heaviest bottoming cuts.

It holds the works perfectly true.

It will accommodate a reasonable variation in diameter.

It does not need undue effort to operate.

It is quick to operate.

It has no projecting parts.

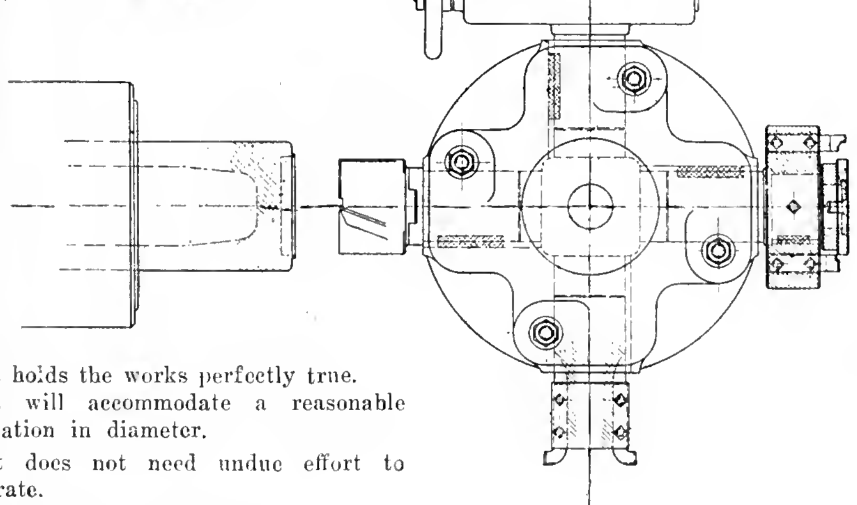
It holds the work without distortion.

Tool Layout

The tool layout for boring, bottoming and facing the latest type of high explosive shells is shown in Fig. 3. Four turret tools are employed, and the first bar which rough bores the parallel portion, has two forged cutters carried in slots at the end, while a round cutter some distance behind takes the first cut in the thread diameter. This type of boring bar is a great producer, and is infinitely superior to a spade tool for parallel boring, as it can be ground with top rake, making it very free cutting, a feed of 30 cuts per inch being used.

For quickly setting the two cutters equidistant from the centre and to the correct size, a setting gauge is provided which fits in a hole at the end of the bar. This is shown in the layout.

FIG. 4. TOOL LAYOUT FOR MACHINING BASE END OF HIGH EXPLOSIVE SHELLS ON NO. 5 SHELL BORING LATHE.



The next tool is a spade drill, which takes up the boring at the point left by the previous bar, and its purpose is to remove the scale from the bottom of the hole. The cutter is approximately to form, but is much easier to feed into the bottom than an ordinary spade tool, owing to the drill point, which cuts through the scale without losing its edge quickly. As it is only a roughing tool, regrinding is quickly done, for the shape is not important, and need not be exactly to form.

The third tool is a spade cutter, correct for diameter and form, which finishes the bore like a reamer, at a feed of 10 cuts per inch, and also trues up the form at the bottom of the shell, the hand worm feed being used for this part of the work, after the automatic feed has tripped. As this cutter has very little to remove, and does not cut on the scale, its life is long, and it seldom needs regrinding.

The last turret bar bores the thread diameter to size, faces the end, and chamfers the mouth. All bars except the last are provided with internal oil supply.

For boring the recess for the base plug, and facing the end, four tools are again used, the layout being shown in Fig. 4. The first is a four-flute reamer cut to centre, which feeds straight into the end of the shell, and roughs out the recess. This is followed by a head carrying two single point cutters for boring to size.

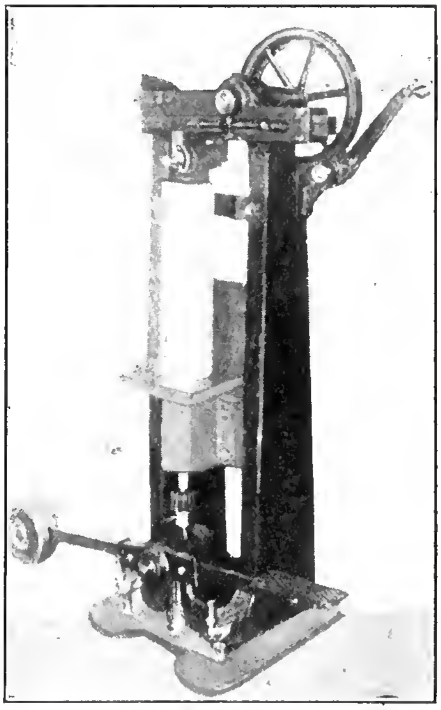
On the next turret face is a head which pilots with a revolving bush into the recess, while two cutters respectively face the end and form the radius.

The facing of the bottom of the recess is done by a traversing single point cutter in the slide facing tool on the last turret face, completing the operations.

MARKING MACHINES FOR HIGH EXPLOSIVE SHELLS

THE photograph herewith illustrates a special machine for marking the base of shells up to 6 in. in diameter and 21½ in. in length. These machines are made in two sizes: Special No. 3A for marking the base of shells up to 12 in., and Special No. 3B for marking the base of shells from 12 in. to 21½ in. in length. The principle involved is the same as the makers Standard Dwight Slate marking machines.

The roll die passes over the base of the shell, and the foot lever raises the table to any desired depth of die so as to give an accurate impression. The No. 3A is arranged with a hand lever, by one pull of which the die revolves and completes the mark. On the No. 3B, in order to get the desired pressure on the larger shells, an arrangement of gears increases the power without increasing the strain on the operator. Shells, it is claimed, can be marked with these machines on the base practically as fast as they can be lifted in and out, as the operation of marking requires only from five to ten seconds. Dies are furnished with these machines to order.



MARKING MACHINE FOR HIGH EXPLOSIVE SHELLS.

The Noble & Westbrook Mfg. Co., Hartford, Conn., are the manufacturers of the foregoing products.

SHELL GROOVING, WAVING AND UNDERCUTTING MACHINE

THE machine shown in the accompanying illustration has been specially designed for cutting, dovetailing and

waving the driving band groove in 4.5 in. and 60-pdr. (5 in.) shells.

The working mechanism is mounted on a short heavy bed cast with an oil pan and mounted on standard legs. Two heavy separate bearings are firmly bolted to the bed; front bearing being $9\frac{3}{4}$ in. diameter x 7 in. long; rear, $5\frac{1}{2}$ in. x 6 in. The bearings are filled with best babbitt, peened in and bored, and finally scraped to fit the spindle. Means of adjustment are provided. The spindle is steel with bearings, etc., finished by grinding on dead centres. The nose or chuck end is fitted with a powerful collet chuck, operated by an air cylinder at the rear end of the spindle.

The drive is through cut gearing from a shaft at the rear, on which is mounted a friction clutch pulley, also operated by air. Two valves are provided so that the chuck or the drive can be operated independently or together.

The feed is through a worm and gear, which in turn connect to cam rods for operating each tool. A knock-out is provided which stops the feed when the proper depth of cut is reached. The cams are drawn back to the starting position by a hand wheel. Independent adjustment is provided for each of the three tools, so that when once adjusted the rear tools reach the finished diameter slightly ahead of the front wave tool. The wave tool is formed to give the correct wave, and is 5 in. long. It is held by clamping into a dovetail by two heavy bolts and sharpened by grinding on end. It is adjusted to the proper height by a set screw below the end of the tool, which prevents any chance of tool moving or slipping out of position. The wave is generated by rocking the tool to follow the wave instead of the usual plan of moving sideways. The movement is positive, as it is controlled by gearing through an eccentric.

The two rear or undercutting tools are very rugged and long-lived, as standard cutting-off tool blades are used, each one 3/16 in. thick by $1\frac{1}{8}$ in. wide. They are clamped into slide blocks set at the correct angle and width for the band groove. All the tools can be taken out, ground and replaced with only one measurement to check—that is, the diameter. This can be corrected with the machine in motion by the adjusting screw which bears on the cam block. The adjustment should be done with the feed out and the point of adjusting screw bearing on the crest of the cam.

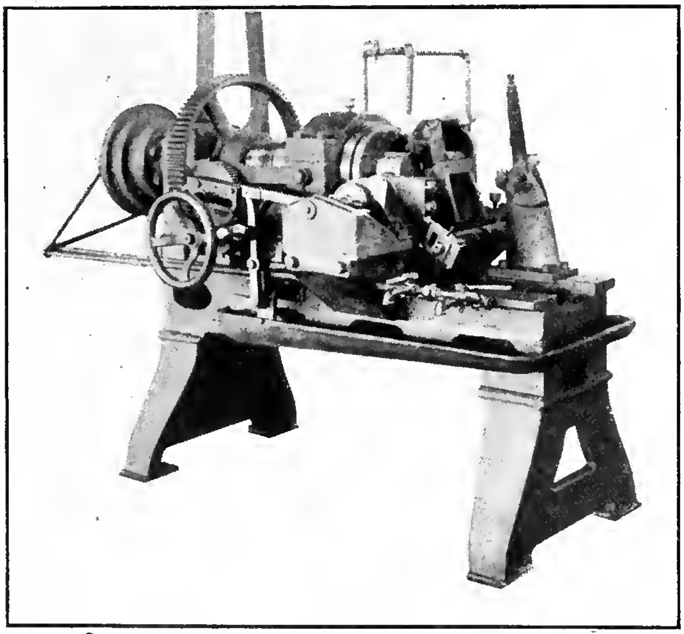
A gear pump is provided, which runs continuously, as it is belted from the driving pulley. Oil or compound is drawn from a reservoir formed in the leg under the bearings. A relief valve is provided to protect pump when in operation.

To operate, place the shell in the shell chuck, swing the stop in place, pull back the shell to the stop, turn on the air for the chuck, then the air for the clutch. Turn the hand wheel until the tools just take hold. Then press down the handle near the hand wheel to raise the worm gear into mesh with the worm on the spindle and turn on the oil. The feed continues until the stop on the front cam rod strikes the knock-off and drops the worm gear out of connection. Shut off the oil and the air from the clutch. Return the cams to original position by rotating the hand wheel. Release the air from the chuck piston and remove the shell.

The machine is semi-automatic in nature, and one operator could easily care for two machines.

For the 4.5 high explosive shells the pulley shaft should run about 200 r.p.m., at which speed the actual cutting time is 3 minutes 10 seconds. For the 5-in. 60-pdr. shell the pulley shaft should run about 180 r.p.m, the cutting time being 4 minutes 35 seconds. Shells can be taken out and another one chucked in about 30 seconds.

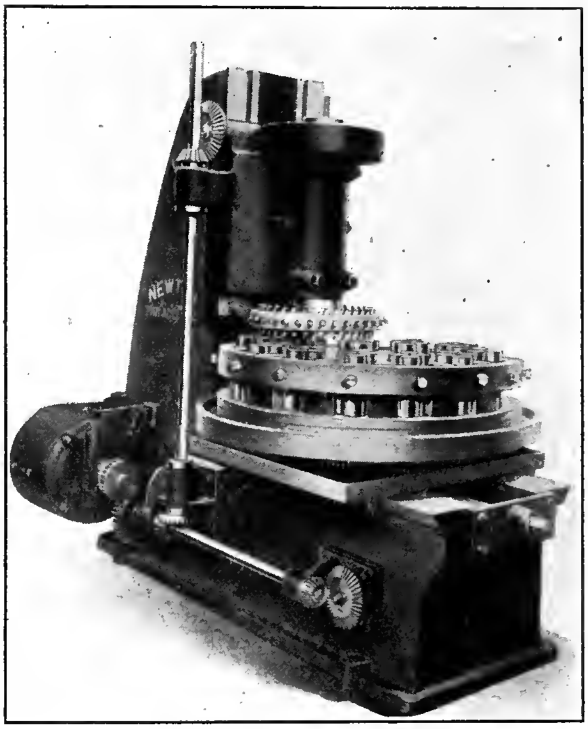
This machine is a recent product of the Jenckes Machine Co., Sherbrooke, Que.



SHELL GROOVING, WAVING AND UNDERCUTTING MACHINE

VERTICAL MILLING MACHINE WITH UNINTERRUPTED FEED

THIS description refers to a vertical milling machine which was built by the Newton Machine Tool Works, Philadelphia, Pa., specially for milling off the solid ends of shrapnel. While the machine in itself is not a new development, the adaptation of the special chuck or fixture for holding the work makes a continuous operation. A 10 in. diameter cutter is carried, and the finished work can be removed and rough shells clamped in the fixture without stopping the feed.



VERTICAL MILLING MACHINE

The method of procedure is to hold the rough turned forgings in the fixture which has a capacity for holding sixty pieces at a time. This is subdivided into pockets, each being arranged to hold five forgings which are clamped with one screw. The work table has three changes of circular feed with hand circular rotation and hand in-and-out adjustment.

Papers Read at the Recent Foundrymen's Convention

Selected from the more important subjects presented for discussion before the Annual Convention of the American Foundrymen's Association and the American Institute of Metals at Atlantic City, N.J., during September, 1915. The papers cover a wide field of foundry and allied activity, the nature of the results and the completeness of the reports making them of particular interest to all who desire to keep in touch with metallurgical progress.

CONCERNING "STELLITE"

By Elwood Haynes.*

THE name STELLITE was coined from the Latin word "Stella," a star. This name was first applied to a binary alloy consisting of cobalt and chromium, which the writer discovered and produced as early as 1899. It was not until some years later that its properties were fully investigated, when it was found to possess the following properties:

1. A considerable amount of hardness, as alloys containing 10 per cent. or more of chromium could not be successfully filed, though the file could slowly wear away the suface of the metal.

2. Considerable toughness. Alloys containing as high as 25 per cent. chronium showing elongation of 10 per cent. or more.

3. Comparatively high tensile strength and elastic limit. A bar of forged metal showing elastic limit of 85,000 pounds and tensile strength of 110,000 pounds.

4. Fine color and lustre. The color of the alloy lies between that of steel and silver.

5. Absolute resistance to oxidation or other changes when exposed to either dry or moist atmosphere at all temperatures under a dull red heat.

In 1911 the writer succeeded in producing very hard alloys (consisting essentially of cobalt and chronium) by adding tungsten or molybdenum or both. The hard alloys thus formed could not be scratched with the file, but in turn would scratch any steel that could be produced. Some of these alloys were extremely brittle, and those used for lathe tools require very careful handling. Some of them that showed excellent cutting qualities when used for turning cast iron or steel would break very easily if subjected to any abnormal stress.

In order to determine the stress required to break a 3/8-in. sq. tool, for example, a small clamp was made in the form of a slot precisely similar to the slot used in the tool holder.

A short piece or bar of Stellite was placed in this slot and pressure applied vertically near the end of the bar at a distance of 1 in. from the clamp. Some of the weaker bars broke at from 100 to 300 pounds pressure under this test. Gradually the strength of the bars was increased until they would readily withstand 1000 pounds, and at this time bars are produced for turning steel which readily withstand from 1,200 to 1,500 pounds under the same test. The very hard bars used for turning cast iron usually stand from 800 to 1,200 pounds under this test. Bars that would stand as high as 1,850 pounds have been produced, but were not found to be equal in cutting qualities to some other compositions of slightly less strength. It should be remarked at this point that the cutting qualities of any steel do not depend primarily upon its strength, but upon the suitable combination of strength, hardness, resistance to wear, etc. The strength of a tool is in reality a question of elastic limit. Steels possessing this quality to the highest degree are nickel steels, nickel chrome steels and vanadium chrome steels. For turning steel and iron, however, they are of little or no value, since they lack in hardness and resistance to abrasion, particularly at high temperature.

Maintaining the Cutting Edge

The virtue of the Stellite tool lies in its ability to maintain its cutting edge at a high rate of speed at temperatures which would immediately cause the failure of any known tools containing any notable quantity of iron. Its great hardness and resistance to abrasion at all working temperatures are likewise valuable properties.

Owing to the fact that Stellite retains its hardness even at a full red heat, it cannot be forged. This fact, however, is rather a virtue than a detriment so far as use is concerned, because if the alloy would soften sufficiently for forging when heated it would, of course, immediately lose its cutting edge at the same temperature and this would limit its usefulness to a marked degree.

A Recent Performance

From the above fact Stellite can only be reduced to the desired form by casting it in dies in the form of bars which are afterward ground to a cutting edge. Its capabilities as a lathe tool are now universally acknowledged, though in certain cases failures have resulted, due to improper knowledge of the alloy and its peculiarities. It should be remembered that it is not a steel and therefore requires special handling, which enables the operator to utilize its valuable properties to the best advantage.

Without going into the method of handling the alloy, some results obtained by its use may not be out of place. It was recently ascertained that a 3/8-in. sq. x 2½-in. long piece of Stellite, ground to the form of a grooving tool, cut 14,000 grooves in cast iron pistons ranging from 3½ in. to 4⅜ in. in diameter before it became too much worn off for further use. This work was performed in regular practice and not as a test. A still more remarkable and more recent performance has just come to light in the same factory. A Stellite tool of the same dimensions as that mentioned above, but which was ground to the round nose form and used for turning pistons, turned off more than 8,000 pounds of cast iron before becoming too short for use. Considering only the portion of the tool which was actually ground away, the tool turned off 1,000 times its weight of cast iron before becoming too short for service.

Both of the above tools were made especially for turning cast iron. Another combination is used for turning steel, which has also shown equally remarkable results. These tools are now being used extensively for turning shrapnel shells at high speed for the European war.

While long wear is an important property in a lathe tool, it is not the essential or most valuable property. The value of the tool, even at the comparatively high price of Stellite sinks into insignificance when compared with the value of the time saved. For example, in the cast iron performance mentioned above, the Stellite cost only about 1c per day, while it effected a net saving of from \$2 to \$3 per day. In other words, it is the value of the output which counts and not the cost of the tool.

*Haynes Stellite Works, Kokomo, Ind.

FOUNDRY EXHIBITION OF 1916

A. O. BACKERT, secretary American Foundrymen's Association, has issued the following statement in his capacity as secretary of a special committee of the American Foundrymen's Association and the American Institute of Metals. Details of the new arrangement for the annual exhibition of foundry equipment and supplies are given in the following letter addressed to the members of the American Foundrymen's Association:

As a result of several conferences, held recently at Cleveland and Pittsburgh, by the special committee empowered by the American Foundrymen's Association and the American Institute of Metals to select the time and place

for the 1916 foundrymen's convention, it has been decided to meet in Cleveland during the week of September 11.

At Atlantic City the executive board of the American Foundrymen's Association authorized the appointment of a committee of five to decide upon next year's meeting place, and this committee was instructed by the American Institute of Metals to serve also in its behalf. This special committee is constituted as follows: R. A. Bull, Commonwealth Steel Company, Granite City, Ill., president of the American Foundrymen's Association, chairman; Joseph T. Speer, Pittsburgh Valve, Foundry & Construction Company, Pittsburgh, and Alfred E. Howell, Phillips & Buttorff Mfg. Company, Nashville, Tenn., past presidents; J. P. Pero, Missouri Malleable Iron Company, East St. Louis, Ill., senior vice-president, and A. O. Backert, Cleveland, secretary American Foundrymen's Association.

The annual exhibition of foundry equipment and supplies, to be held concurrently with the meetings of these organizations, will be conducted under the auspices of the American Foundrymen's Association and the American Institute of Metals. This decision was reached after mature deliberation and represents the unanimous action of the members of this special committee. It also has been approved heartily by J. S. Seaman, Seaman-Sleeth Company, Pittsburgh, past president of the American Foundrymen's Association, and Jesse L. Jones, Westinghouse Electric & Mfg. Company, East Pittsburgh, Pa., president of the American Institute of Metals, with whom the members of the special committee met for counsel.

Since the interests of manufacturers of foundry equipment and supplies, who make exhibits at these annual shows, and the members of the American Foundrymen's Association and the American Institute of Metals are mutual, it is the sentiment of this special committee that the exhibitors should share in the profits, to be paid in the form of rebates on the cost of their space.

The exhibition will be held in the Cleveland Coliseum, located on Thirteenth Street, in the centre of Cleveland's business district. The Coliseum is within one block of the Hotel Statler, three blocks from the Hollenden, and is only a short walking distance from the other Cleveland hotels. It contains 60,000 sq. ft. of floor space on one level and is admirably adapted for a foundry show.

Sealed proposals have been invited from corporations and individuals capable of conducting exhibits, which are to be submitted to the secretary of this special committee, A. O. Backert, Twelfth and Chestnut Streets, Cleveland, Ohio, on or before 12 o'clock noon, Eastern time, Saturday, November 13, 1915.

This communication has been authorized by this special committee, and its secretary has been instructed to notify you of the action taken.

RE-SHARPENING OF FILES

IN a paper entitled "Machine Shop Equipment, Methods and Processes," before the recent International Engineering Congress, E. R. Norris described the operations involved in re-sharpening files as follows:—

A sand blasting apparatus is being successfully used for file sharpening, by several large manufacturing establishments. This consists of a sheet-iron chamber provided with uptake, settling tank, slurry mixing-tank, slurry overflow pipe, air agitating pipe and slurry projector. A door gives access to the inside of the chamber. The slurry projector is inclined to the horizontal at an angle of 25 deg., and the nozzle extends slightly within the chamber. The projector consists essentially of a bronze body to which are fitted steam pipe, slurry suction-pipe and nozzle. The steam supplies sufficient water for the slurry.

The files are sharpened by being held in the slurry jet in such a manner as to expose the backs of the file teeth to the cutting action of the sand. When the file has been sharpened, it is cleaned and dried by the steam, after the slurry supply has been cut off by a foot lever.

Success in file sharpening depends on the skilful selection of the files to be sharpened, maintenance of the correct angle between files and jet while sharpening, and the selection of a suitable sand. Experience shows that a sharpened file often does as much work as a new one, and the cost of sharpening averages about one-fifth of the cost of new files. The following results have been obtained under ordinary manufacturing conditions and may be taken as representative of the economies which are effected by the efficient use of this apparatus.

No. of Files Treated		Size, In.	Total cost Sand Blasting	Recut Price	Price of New Files
109	...	4	$ 0.88	$	$11.99

GAS ENGINE EFFICIENCY

AT full load under the most favorable conditions, the indicated horsepower of a gas-engine is 88 per cent. of that of an ideal-engine working with a similar mixture. This holds true for all except very weak mixtures; for which the relative efficiency is lower. For mixtures containing only a slight excess of air, the above corresponds to an absolute thermal efficiency of 27 per cent. at a compression ratio of 3.75, and 33 per cent. at a compression ratio of 5.6; for mixtures containing twice the amount of air required for complete combustion the absolute efficiencies are 29 per cent. and 36 per cent. The indicated efficiency relative to the gas-standard falls from 88 per cent. to 84 per cent. between full and no load.

At full load, the brake efficiency reative to the gas-standard varies from 70 per cent. at the compression ratio 3.75, to 67.5 per cent. at the compresion ratio 5.6; this holds true for all except the weakest mixtures, for which the relative efficiency is lower. The absolute brake efficiency is 21 per cent. at compression ratio 3.75, and 25.5 per cent. at compression ratio 5.6 for mixtures containing little excess of air, and 23 per cent. and 27 per cent. respectively for mixtures containing twice the amount of air required for complete combustion. The maximum brake efficiency obtained in the author's experiments was 27.4 per cent., and this occurred at the highest compression ratio for a mixture slightly stronger.

At light loads, the brake efficiency relative to the gas-standard decreases more rapidly as the compression ratio rises. For the higher compression ratios the increase of theoretical efficiency is just counterbalanced by the increase in frictional loss, and thus the absolute efficiency remains constant.

The mechanical losses increase slightly in absolute amount with the load and with the compression ratio. For the engine under test (a 25 h.p. National gas engine) at normal speed (200 revs. per min.) the mechanical losses amounted to 5.6 h.p. at no load and 6.3 h.p. at full load when the compression ratio was 3.75; and 6.5 h.p. at no load and 7.0 h.p. at full load when the compression ratio was 5.6. The pumping losses were an important part of the total mechanical losses; at a compression ratio of 4.85 they represented 2.3 h.p. at no load and 2.1 h.p. at full load, or 38 and 31 per cent. of mechanical losses.

The loss of power due to thermal losses at full load under most favourable conditions amounted to 12 per cent. of the total available energy, and at no load to 16 per cent.; of this less than one quarter was due to heat transmission during the expansion.

From a paper read at the recent British Association meeting.

IS A STEEL FAMINE REALLY IMMINENT?

IF the unexpected always happens, it might reasonably be argued that the expected never happens. Present reports and future prospects, however, would seem to justify many of the assertions which are being made regarding the inability of steel makers to meet the present demand, although, whether the demand is liable to increase still further, is at the moment largely conjecture.

As the largest producer of steel in the world, the United States is enjoying a period of unprecedented activity. That this activity is directly due to the war there can be no doubt, for while many observers credit the scarcity of steel to a greatly increased home consumption, it is obvious that much, if not nearly all of this domestic activity in the States developed after the placing of war contracts by the belligerents.

Reports as to the actual rate at which munition and other contracts calling for steel are being filled are not available for obvious reasons, but, if judged by the experience of manufacturers in this country, production should be well on to the maximum. It is true that an increase in Canadian consumption may result from the recently placed contracts for large shells, but that such an increase will result in a state of affairs approaching a steel famine seems hardly probable.

The uncertainty regarding developments in the war during the next few months is sufficient to prevent accurate forecasting of the industrial situation. The success which has attended the organization of national arsenals and controlled munitions plants in Great Britain is reducing the tendency to distribute shell orders broadcast as has been done recently. Consequently, when the present high peak of production has been passed, the consumption on this account may be expected to decrease.

The recent arrival on this side of the ocean of French Government officials regarding the assistance which could be rendered by American firms in the ultimate period of construction points to a possible continuance of consumption which, under the circumstances, might be of extended duration rather than of excessive urgency. The fact that British steel makers are extending their plants with all possible haste should not be lost sight of in its bearing on the steel market in this country.

While many furnace companies are endeavoring to place further orders for ore, indicating the probability of a shortage on docks during the winter, British firms are able to procure a steady supply of ore from Spain with which to increase their output. The close contact of Belgian, French and British officials and manufacturers discounts the probability of reconstruction opportunities being overlooked or suffering from lack of preparation by European manufacturers. The recovery of the Minette ore mines and the Alsace deposits by France will stimulate manufacturing in many ways, but as by that time, the demand for munitions may have decreased somewhat, the present highly organized industry of France may well be expected to resume production promptly and largely.

The nature of financial relations between Europe and America may not be without a retarding effect on the future steel trade between the two continents. The necessity for observing every available financial and industrial economy is becoming more apparent every day, and even later, when the tide of events is undeniably set towards Allied triumph, the necessity for economy will not be any less urgent.

Under these circumstances, and in the absence of further immediate increases in domestic consumption, the supply of steel may not fall so far short of the demand as to assume the nature of an absolute famine.

The commercial activity throughout the country which results from and reacts upon the steel industry in times like the present creates demands which do not partake of the urgency of war orders. Additions to rolling stock, building operations, county and municipal improvements, and many other undertakings of a similar kind are limited in their rate of progress by the cost of construction. The dull times in Canada and the United States which preceded the war, prevented the placing of much business, which, had it been gone on with, would have caused the present situation to be much more acute.

The highest bidder does not always get the material, and just as some firms across the line have an eye to their own permanent customers, to the refusal of export business, so will Allied interests encourage the formation of connections which, while of more than urgent necessity at the present moment, will later assume an economic value out of all proportion to their present cost.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, Que., Nov. 22, 1915—Optimism arising from the harvesting of a record crop continues to develop, and the general feeling is that even should the demand for war supplies tend in coming months to show a falling off and ultimately cease, an era of industrial prosperity is in process of materializing. The turn of the year is expected to bring about much activity in railroad betterment and shipbuilding, the latter probably attaining a prominence hitherto unknown in Canadian experience.

Pig Iron

The demand for pig iron for steel making continues to tax the blast furnaces to capacity. Producers are filled up with orders for months ahead and are not inclined to take futures until they see the effect that the present conditions will have upon the market. Some are holding out on orders with the expectation that higher prices will prevail. Local dealers have not further advanced prices, but state that an increase may be made before the close of the present month.

Steel

Last week's action of the United States Steel Corporation in withdrawing quotations on foreign trade, does not mean that this condition of affairs will prevail for any great length of time, as similar steps have been taken in the past when domestic conditions showed signs of congestion. The present situation is the result of most of the mills being booked up several months ahead and because many of them are unable to give delivery until well into the first half of the coming year. The needs of the war have taken precedence over the domestic demand, and the latter is therefore suffering to some extent.

United States quotations show advances, but locals remain unchanged. However, all indications are that prices will show sharp advances in the immediate future.

The abnormal demand for high speed steel is putting this necessary material almost beyond the reach of the manufacturer. Present quotations range from \$2.50 to \$3.00 per pound.

The demand for sheets continues brisk, with prices unchanged.

Machine Tools and Supplies

Little or no change is noted in the machine tool situation. The demand for certain tools continues, but with uncertainty of delivery. Many shell-making establishments are receiving machines which were ordered six or eight months ago, and supplementary machinery is being secured wherever possible.

Within the next two or three months, those firms successful in securing orders for the large shells will be equipping plants with heavy tools, suitable for the work.

Metals

The metal situation is gathering strength and quotations are advancing. Heavy demands and increased activity in the copper trade is responsible for the advance of the past week. The abnormal consumption of copper by the large manufacturing centres far exceeds that of any previous record.

Copper—Producers are beginning to feel the strain of the demand for copper, and the Lake companies have, in some instances, declined to give quotations, as they carry orders that will take many months to fill. Many of the buyers for war purposes are not yet satisfied, and further advances are looked for. Domestic demand is below normal. A general advance of 1c per lb. is shown in this week's figures. Lake copper, carload and electrolytic is quoted at 21 cents per pound, while casting has advanced to \$20.50 per hundred pounds.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion \$100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

Tin—Developments in the tin situation are keeping the markets in a state of uncertainty. Conditions in the Mediterranean and the Suez Canal continue to keep prices strong. The advance of \$7 noted in last week's quotations is this week increased another \$3, making an increase of \$10 per 100 lbs. in two weeks.

Spelter—This keeps very firm with advances shown in all quarters. The scarcity shown in London lately has resulted in an advance in price, and immediate delivery is securing good figures. Future delivery is also holding firm. Local dealers have advanced their prices \$20 per ton and are now quoting 20 cents per lb.

Lead—Local dealers report firmness with the usual activity and a slight advance over the previous week. Present price per 100 pounds is \$6.75.

Antimony—This is still showing a tendency to advance. Buying is heavy, due to the increased call of war munitions. This week shows an advance to \$42 per hundred pounds.

Aluminum—This keeps firm at 62 cents per pound.

Old Materials

Dealers in scrap metals report business normal, with no advance in prices. However, the situation may call for many changes before the close of the present week. The advances shown in the various metals will naturally have their effect upon old material and increases are looked for shortly.

Toronto, Ont., Nov. 23.—The greatest activity continues in the steel trade and munitions industry, while the industrial situation generally is looking brighter. Both domestic and export trade is improving and there is a more optimistic feeling with regard to the future outlook. Conditions are to a considerable extent abnormal, and the slackening in trade usually experienced during the winter months will probably not be so noticeable this year. War orders will assist materially in keeping factories busy and make up for loss of normal business. Indications point to considerably less unemployment this winter and to improved economic conditions throughout the country.

That the export trade continues to increase in volume is clearly shown in the trade returns for October recently issued by the Department of Trade and Commerce. The exports for the month were valued at eighty million dollars, or nearly double those for the corresponding month of 1914. The total Canadian trade for October, 1915, was eleven million dollars ahead of October, 1914, while for the seven months of this fiscal year the increase is sixty-nine million dollars more than for the corresponding period of last year. An interesting feature of the business expansion is the continued improvement in the balance of trade towards this country.

The situation with regard to the munitions industry is practically unchanged. Orders for the large calibre shells are being placed, but in what quantities is not generally known. The Munitions Committee has fixed the price of steel for shells at 3½ cents per pound. A shortage of copper bands has developed and is causing considerable inconvenience to some firms working on shells.

Successful Production of 4.5 in. Shells in a Stove Foundry

Staff Article

Shell making in Canada has passed well beyond the novelty stage and may easily be designated as having assumed a place of prominence comparable with the most outstanding and successful of our hitherto established metal-working industries. In many instances, output of finished shells is being developed to such an extent to meet the requirements of our Munitions Committee, that the regular lines of the firms engaged have almost ceased to exist.

THE plant from which this article was obtained is still engaged in stove-making, but their greatest meantime activity, like many other concerns, is in the manufacture of 4.5 in. high explosive shells.

Having little or no machinery with which to commence shell operations, it was some time before much progress was apparent; but after several months of preparation, a large store house, adjacent to the foundry, was equipped with machine tools suitable for the purpose, and in a short time an output of 400 finished shells per day is expected.

The present plan of the machine tool layout is shown in Fig. 1. The larger section of the building is one storey high, the portion to the left being of two-storey construction. It is intended to move the tool room to the floor above and use this space for additional manufacturing equipment

In the plan layout the numbers indicate the various operations on the shells as they proceed through the shop:—(1) Cut off and face base; (2) Centre base; (3) Rough turn; (4) Boring; (5) Face base; (6) Nosing; (7) Bore and thread nose: (8) Rough outside diameter and contour; (9) Finish outside diameter and contour; (10) Grind; (11) Weigh and test; (12) Doctoring; (13) Rough groove; (14) Wave and undercut; (15) Rough and base; (16) Finish base and recess; (17) Rivet base plate; (17A) Saw off square; (18) Face and finish base; (18A) Brass sockets; (19) Press on copper band; (20) Turn copper band; (21) Marking base; (22) Sand blast; (23) Varnishing; (24) Baking; (25) Inspection; (26) Painting.

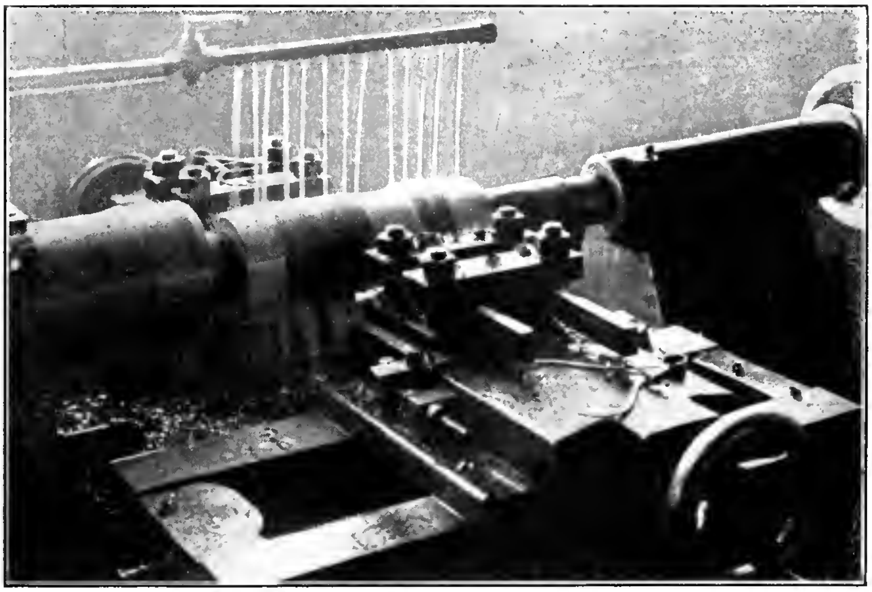

FIG. 2. ROUGH TURNING SHELL BODY.

The shell forgings are brought in at the door A, and after going through the sequence of operations are finally taken through the door B, where they are crated in readiness for shipment. The numbers refer to the various operations upon the shells, as they take their course through the shop, during the successive stages of completion.

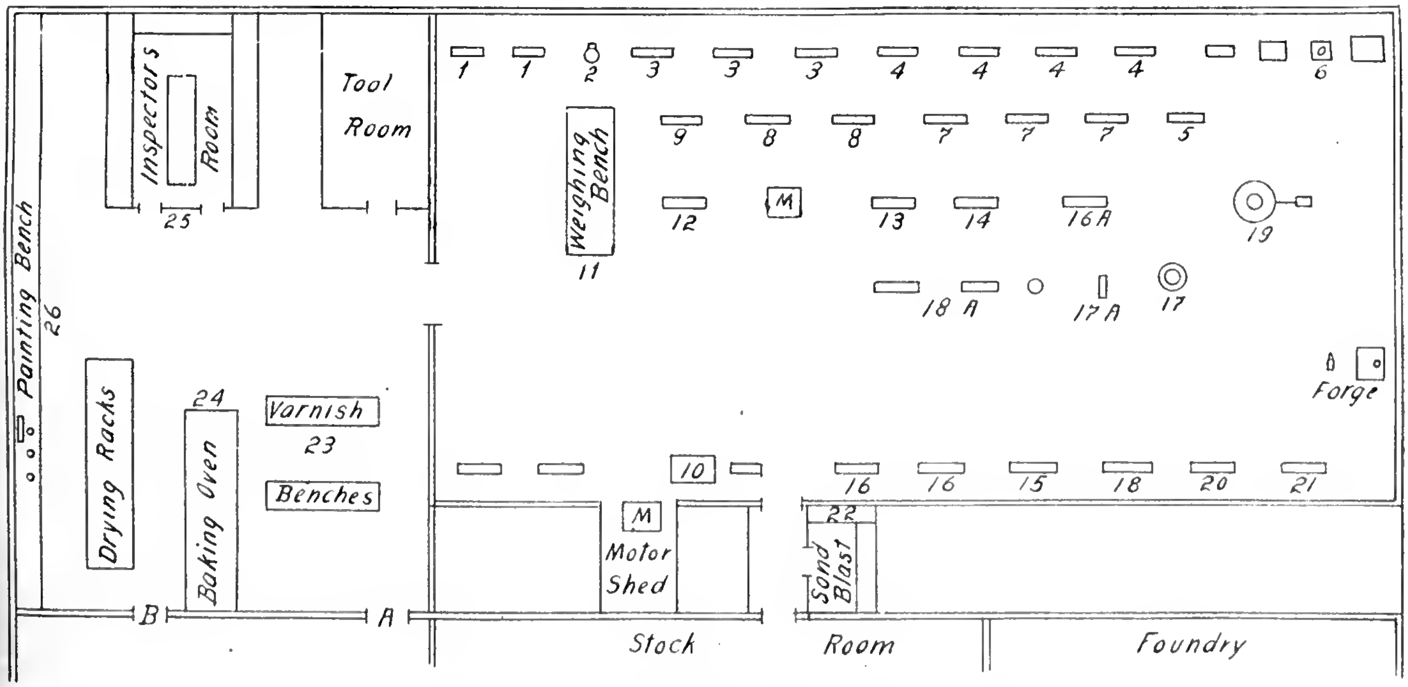

FIG. 1. SHOP PLAN, ALSO NUMBERED SEQUENCE OF OPERATIONS.

Cutting Off and Centreing

The first operation, that of cutting off the open end and roughing off the base is performed on two "Hall" cutting off machines; an average production of 125 a day of ten hours being obtained on each. After this operation the shells are placed upon a jig secured to a drill table

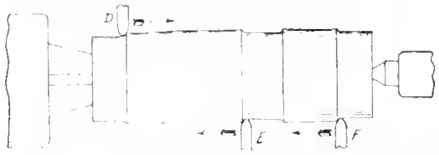

FIG. 3. TOOLING DIAGRAM, ROUGH TURNING SHELL BODY.

and the base centered with the rough bore of the forging.

Rough Turning

Rough turning the outside diameter is the third operation. This is accomplished on one Cincinnati Pulley Machine Co. lathe, with an output of 9 to 10 shells per hour, and on two J. B. Reed, 24-inch engine lathes, with an average production each of 78 per ten hours. On these last two lathes the cone pulleys have been altered to accommodate a 5-inch belt to secure increased power. (Fig. 4.)

A view of the "Cincinnati" lathe in operation is shown in Fig. 2. Three cutting tools are at work on the shell body, two at the front and one at the rear of the lathe. The front tools are fed into position, the forward tool commencing the cut about one-third of the shell length in advance of the other which starts operating on the base end of the diameter. The single tool at the rear is started at the open end of shell and travels toward the base. The setting of the tools is adjustable by the stop shown to the left of the front cross slide. By this method the rough turning is completed when the tools have travelled a fraction over one-third of the shell length.

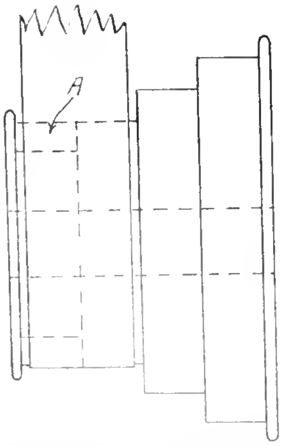

FIG. 4. CONE PULLEY EXTENSION FOR ROUGH TURNING BODY.

The position and action of the tools can be clearly seen in Fig. 3. While the two front tools E and F are advanc-

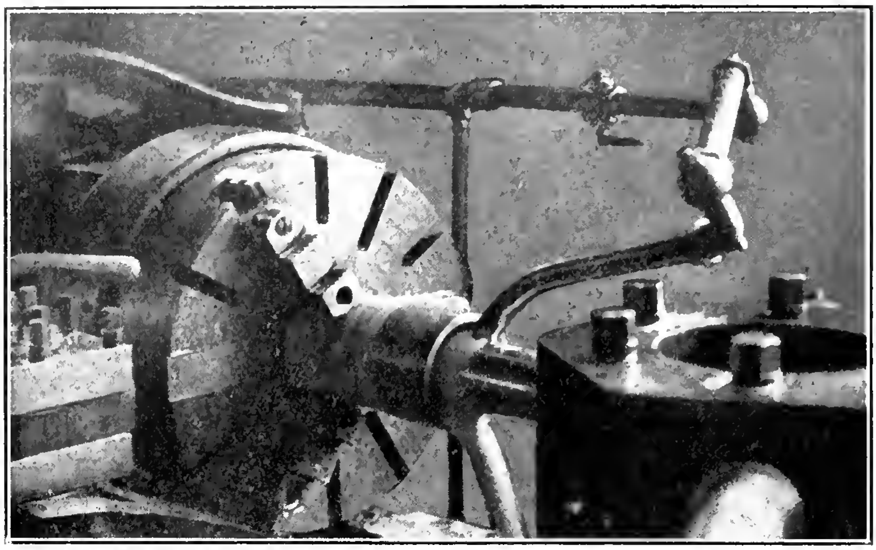

FIG. 5. BORING OPERATION ON "LIBBY" LATHE.

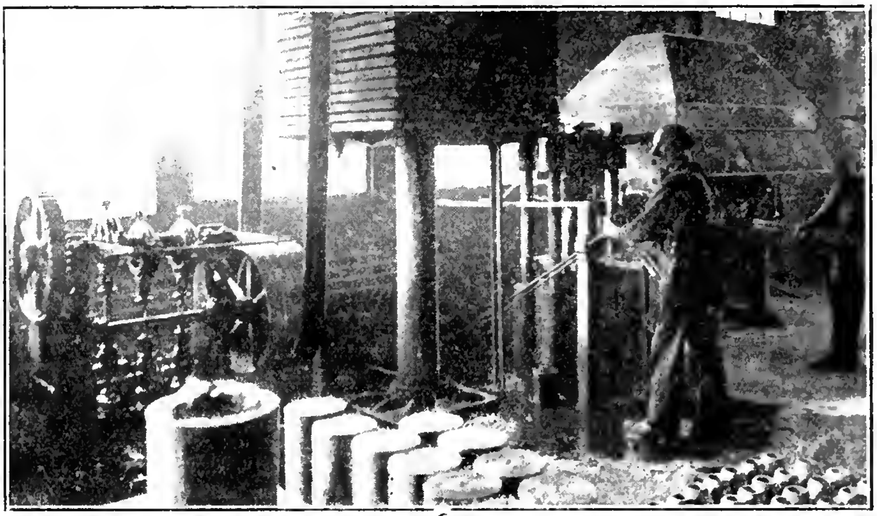

FIG. 6. SHELL NOSING EQUIPMENT.

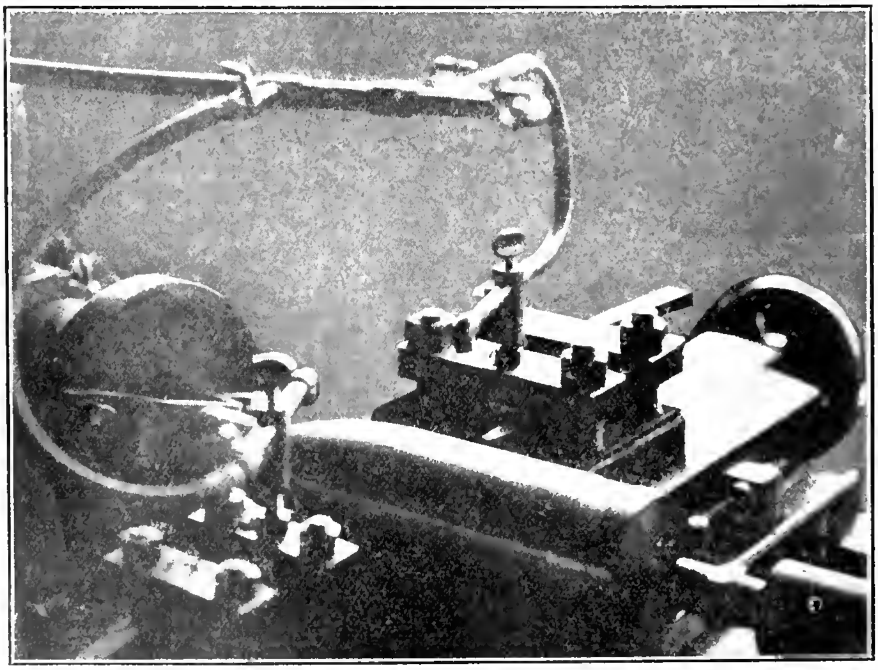

FIG. 7. ROUGH TURNING NOSE PROFILE AND BODY.

ing toward the headstock, the rear tool D is traveling in an opposite direction.

Boring

The fourth operation, boring the internal diameter and forming contour of base is done on three "Libby" turret lathes, also on one heavy duty "Le Blond" 26-inch engine lathe, fitted with special turret constructed in the shop. On the "Libby" lathes, shown operating in Fig. 5, the chuck was bored out a little larger than the diameter of the rough turned body, so as to allow the shell to be gripped in the centre, thus securing greater rigidity and increased output. The latter averages 65 in ten hours. The chamfers from the two outside diameters is put on by a tool in the cross slide while the bore is being finished. All cutters and cutting tools are made of "Firth's Speedicut" steel.

Refacing Base

After the shells have been bored, the base is faced off perfectly square, as any deviation from the vertical position might cause trouble when the mouth of the shell was being closed in. When facing off the base at this stage, 1/8 of an inch is allowed over the finished dimension to obtain a narrow flange for riveting over the base plug.

press the stock at the lower portion of the contour, and the shell when nosed may be too short. On the other hand, if the nose has not been heated sufficiently increased strain is put upon the nosing die, which may result in its breaking.

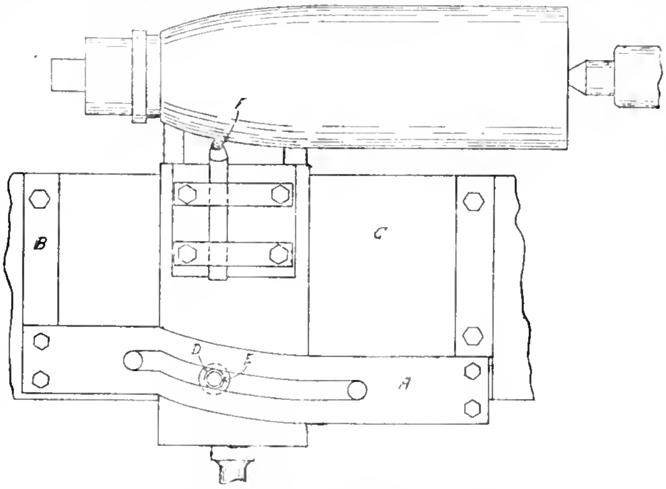

FIG. 8. PROFILE TURNING DEVICE.

The shells when heated, are placed in a "Perrin" press, equipped with a water cooled cast iron chilled die, and the nose formed. The hydraulic press derives its power from the accumulator shown, which is controlled by a three-cylinder belt driven pump installed by the W. R. Perrin Co., of Toronto.

Annealing

Following the nosing operation, the shells are placed in boxes of lime to anneal in readiness for further machining.

Roughing Outside Contour

Rough turning the outside diameter and contour of nose is the eighth operation. This is being accomplished on the Cincinnati Pulley Co. lathe shown in Fig. 7. While the tool at the rear is working on the parallel portion of the shell, the front tool is operating on the profile of the nose. The travel of the tool is governed by the run of a roller in a cam, shown in Fig. 8. The advantage of the two tools working in unison is the accomplishing of the desired result in about half the time ordinarily taken.

In Fig. 8 the brackets B which carry the cam plate A are secured to the ways of the lateral slide C. The stud E carrying the roller D is screwed into the cross slide which supports the cutting tool F. In setting the tool, care must be taken in order to have the cutting edge in line with the centre of the roller, in other words, the cutting tool should be in the same location on the shell profile, as the roller in the cam slot. It should be borne in mind that the shape of the profile produced is governed by the path of travel of the centre of the cam roller. An output of 20 shells per hour is obtained from this operation.

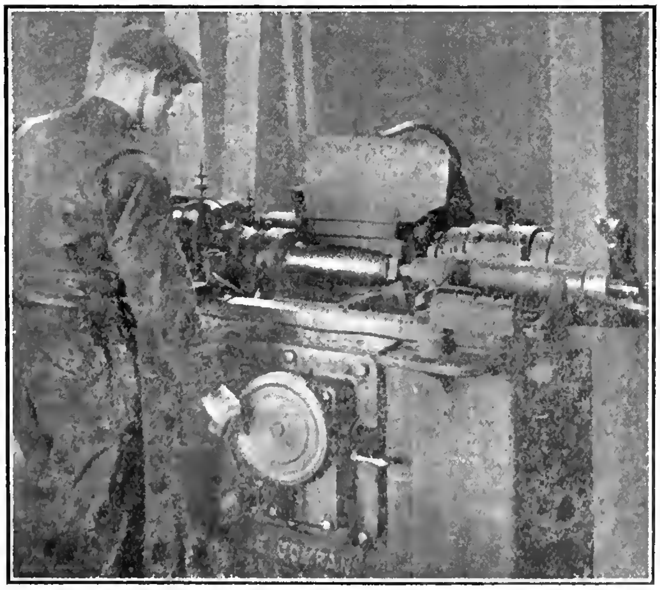

FIG. 9. SHELL BODY GRINDING

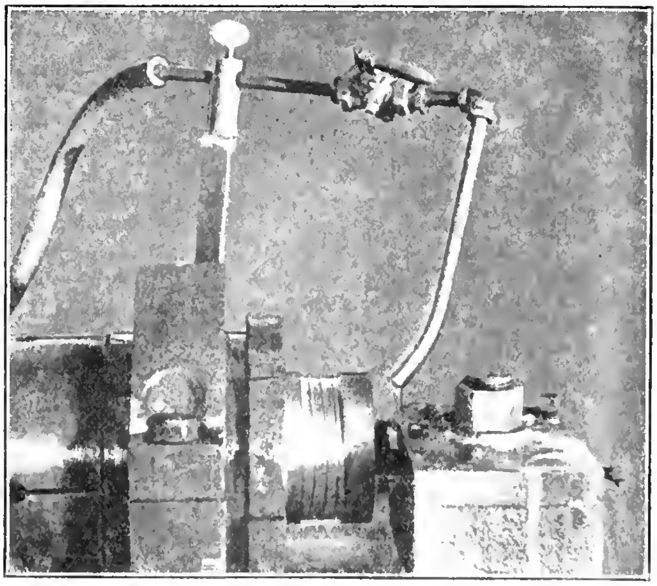

FIG. 10. ROUGHING-OUT BASE RECESS.

Heating and Nosing

The sixth operation, shown in Fig. 6 consists in nosing the shell. The Mechanical Engineering Co. furnace shown at the extreme right, heats the shells to the desired temperature, but to obtain good results much depends upon the experience and judgment of the heater. If the shells are heated too far down, the action of the closing-in process will com-

Threading the Nose

The boring, shaping and threading of the nose is the seventh operation. Two 20-inch "Walcott" engine lathes, fitted with special turrets designed and made in the shop, are used on this operation. The daily output, 24 hours, from these machines is over 400 shells.

Finish Turn and Contour

The shells now receive a finishing cut over the entire surface to bring them to the correct dimensions. This is performed on an 18-inch "Walcott" engine lathe fitted with a cam device, attached to the rear of the lathe.

Grinding

In some instances, where the shells have been found too large after the fin-

ish turning process, due to wear of tools or excessive hardness of material, it has been found necessary to grind the external surface. This is done on the "Ford-Smith" grinder equipped with

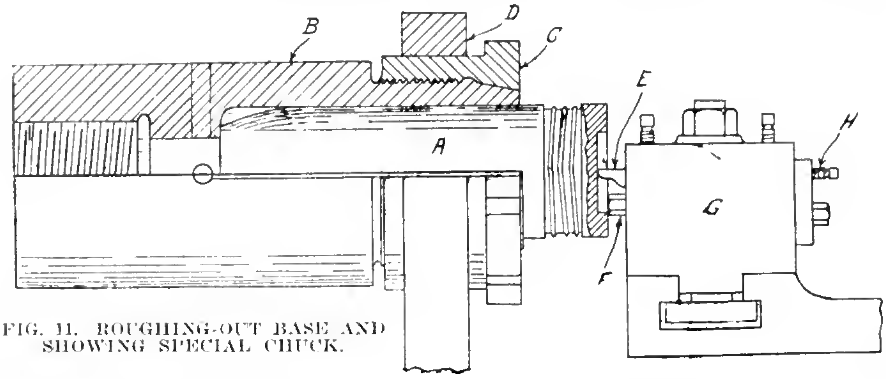

FIG. 11. ROUGHING-OUT BASE AND SHOWING SPECIAL CHUCK.

"Canadian Hart" wheels, and as shown in Fig. 9.

Weighing and Doctoring

The eleventh operation is the weighing and testing. Shells at this stage found to be overweight have the surplus stock removed from the base. This is done in what is called the doctoring lathe (12) which also takes care of other corrections that may be required at different periods during the progress through the shop.

Wave and Groove

The next operation is the roughing out of the copper band groove. Contrary to the general practice, this plant is roughing out the groove in one operation and waving and undercutting in another. These operations, although performed

FIG. 12. RIVETING-IN BASE PLATES.

separately, are done on one lathe; an extra head and attachment being placed on the bed of a 26 in. "Bertram" engine lathe equipped with a "Bertram" waving and undercutting attachment.

Thirty-two shells per hour constitute the output from this machine.

Roughing Out Base

The base is now roughed out on a "J. B. Reed" 20-in. engine lathe fitted with special drive. This is the fifteenth op-

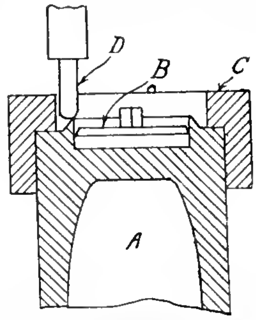

FIG. 13. SKETCH SHOWING BASE PLATE RIVETING ARRANGEMENT.

eration and is shown in Fig. 10. A sketch of the special chuck and tool arrangement is seen in Fig. 11. The shell A is held in the chuck B by closing the nose with the nut C. The rear portion of this nut is turned to fit the bore of the steady rest D. This design allows the chuck to

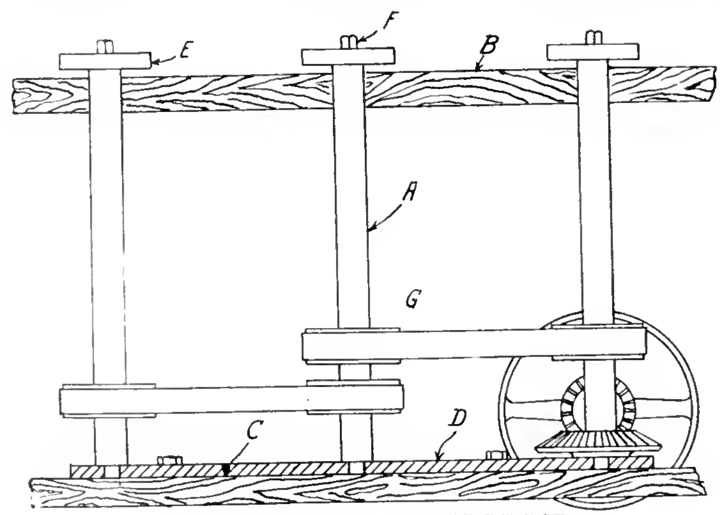

FIG. 15. SHELL PAINTING DEVICE.

be supported close to the point at which the pressure is being applied. The tool E is forced into the metal until the stop F reaches the base of the shell, while the

screw H adjusts the depth of cut and also helps to take the lateral thrust. An output of 150 to 180 shells is obtained in ten hours.

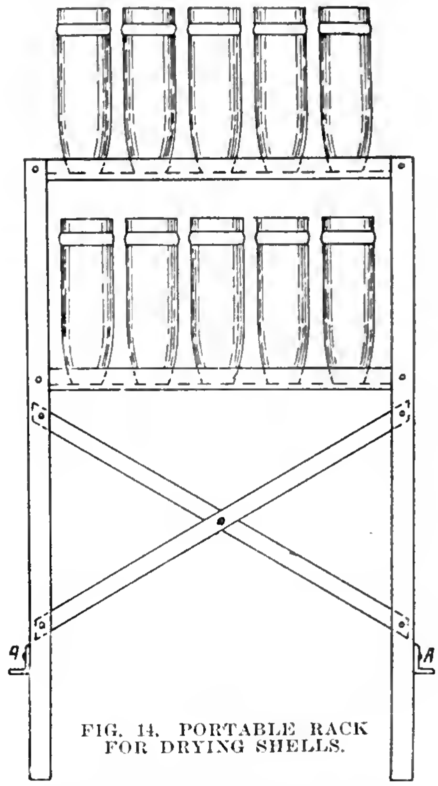

FIG. 14. PORTABLE RACK FOR DRYING SHELLS.

Finishing Base Recess

After the bases have been roughed out, the shells are taken to two "Walcott" 18-inch engine lathes, and the recess and base finished to receive the base plates, which are previously machined in a "Bardons & Oliver" turret machine.

Riveting in Base Plate

The base plates are placed in the recess and the shell held in a chuck secured to a standard on the floor, as shown in Fig. 12. A gauge C, Fig. 13, is placed over the bottom of the shell to guide the position of the hammer D, when riveting in the base plate B. When the riveting has been partly finished, the shell is re-

moved and the square on the plate cut off in a "Racine" power hack saw.

The base plate is next faced off flush and the riveting completed. The base of shell is then finished and the corner rounded.

Brass Sockets

The brass sockets are now screwed in and turned, and the small hole drilled and tapped to receive screw for time fuse. At present the sockets are being screwed in by hand with a pipe wrench, but it is contemplated to adopt some method whereby the work will be performed by the use of a power machine.

Copper Banding

The nineteenth operation, that of pressing on the copper band is done on a "Lymburner" hydraulic banding press. This is operated by a pump of the same make.

Turning the copper band is the next operation. This is done on a "Lodge & Shipley" 22-inch engine lathe, equipped with a "Lymburner" band turning attachment. The production on this machine is about 25 per hour.

A "Brown-Boggs" marking machine is used to officially stamp the base of the shells.

Sand Blast and Varnishing

The shells are next taken to the sand blast room and thoroughly cleansed of all cuttings, oil and other foreign substance. This is necessary so that the varnish will have a uniform thickness over the entire interior surface.

Following a preliminary inspection, the heated varnish is poured in and out again, after which the shells are put on a portable stand, Fig. 14, and placed in a baking oven for several hours. This stand has two shelves each containing 25 shells and near the bottom of the legs are two pieces of angle iron (A) in such a position that the "Chapman" elevating truck can be used in transferring them about the shop.

Painting

After the baking process the shells are taken to the Government room for final inspection, and from there to the painting department. The arrangement used for the latter is shown in Fig. 15. The three shafts (A) extend through the bench (B) to a bar (D) secured to a lower member of the bench (C). These shafts revolve by means of the mechanism shown. The shells are placed in the cup plates E and are revolved by the square F which fits into the hole in the socket plug. They are finally put up in boxes, two shells to each box, ready for shipping.

THE AUTOMATIC MACHINE

THE automatic machine often offers a reduction in labor cost that more than offsets the increase in overhead charges which it incurs. Conditions of the labor market are sometimes such that the automatic is used even where the total cost of its product is known to be somewhat higher. It is undoubtedly true that there are many cases of hand turret lathes being used when automatics would be more economical, and there are certainly a great many cases when the reverse is also true. The merits of any particular case must be decided by the exercise of unusually good judgment; or, better, by a study of costs which takes the overhead charges into account as well as the labor cost.

In this connection it may be noted that the manufacturing cost of high-grade machinery is usually made up of about one-third direct labor, one-third material, and the other third overhead charges of various kinds. Of these three items, that of material is not greatly affected by the style of machine used. In large work the hand machine tends to reduce the overhead charge, while the automatic machine tends to reduce the direct labor change.

Automatics and Quantity Production

If there is demand enough for an article to support large establishments for its manufacture, and if there are no patent or other restrictions to keep its manufacture in the hands of men of limited ability, the normal tendency is toward quantity manufacture. The cheapening of production by using automatic machinery on large lots is an important factor in this tendency.

If the article of manufacture can be standardized, so that the design changes little from year to year, the advantages of large scale manufacture are still more apparent. Machines can be kept on one piece continuously day and night, if necessary, until worn out. Operators can be trained to great skill, not only in getting large output for the comparatively few pieces or operations in their repertoire, but in getting a high grade of workmanship as well, where that is necessary. Special machines, each built for one operation only on a single piece of work, can be profitably used.

Such a manufacturing system also has its disadvantages. The most obvious of these are the necessity for keeping the product free from change as far as possible; and, also, the monotonous character of the work from the operator's standpoint. Of course, no industry is fit for large scale, intensive manufacture until the product is fairly well standardized; or at least until the particular design selected for manufacture is such that it will suit a large percentage of possible customers. To increase the field of customers, such an establishment is in a position to offer attractive low prices for its standardized output, in place of the frequent novelties and special features offered by smaller manufacturers.

There is also something to be said for such an establishment from the standpoint of the workman. An immense amount of ability, of the highest order, must go into its management; and its organization furnishes opportunities for many such men. On the other hand, for workmen of faithfulness and dexterity, but small originality, it can and ought to furnish work at higher wages than they could obtain in any other employment. Many skilled workmen, as well, find these high wages a compensation for the monotony of continuous work on one piece.

From a paper presented at the International Engineering Congress, San Francisco, by Ralph E. Flanders, manager, the Jones & Lamson Machine Co., Springfield, Vt.

LUBRICATING CHAINS

SOMETIMES lubricating chains are employed instead of rings for bearings, the idea being that the chains touch the shaft through a longer arc, and, therefore, are supposed to be kept in motion more surely than plain rings. It must be remembered, however, that the part of the chain immersed in the oil bath offers greater resistance than a plain ring, so that in actual practice there is not much difference between the working of chains and the working of rings. At high speeds there is the disadvantage with chains that the links, when passing through the oil, churn it up. This makes it more difficult to prevent leakage of oil from the bearings.

Satisfactory lubrication of dynamo bearings, i.e., cool running and inappreciable wear, is very important. If wear takes place this means that the rotor is lowered, and the magnets will then exert a pull in a downward direction, which further increases the pressure and accordingly the wear of the bearings.

EVERY applicant for a position undergoes an appraisal based on outward appearances. This initial valuation may or may not be correct, but it counts for a great deal with most employers, for the average employer flatters himself that he is an excellent judge of human nature at sight. First he looks at the features, then at the garments of the man, or he takes in both at a sweep. Instantly he classifies the applicant, and, since he has made this tentative classification, is slow to change it. Engineering and Contracting.

Large Shells: Production Problems and Possibilities--III.

By C. T. D.

In preparing to undertake the production of large shells up to 9.2 in. dia., manufacturers will encounter problems of a nature altogether different from those connected with 18 pdr. shells. Automatic machinery will not be so applicable to the larger sizes, and productive ability will centre largely on such points as sequence of operations, tooling methods, etc.

THE operations listed in group B are those which would be actually required if group A has been performed in the order shown. If the nose has been centred only and not drilled through, it may now be drilled very close to the finished size, leaving only sufficient for a light cut with the boring bar in operation B 3.

One point in favor of centering the nose only and not drilling through in group A, is that it allows the shell to be positioned by the point of the arbor which acts directly against the inside surface of the nose, whereas if the hole be drilled first, the end of the arbor has to be formed of three points making contact on a circle larger than the hole. This point of contact is situated on the tapering part of the nose, and any slight variations in the profile, or irregularities in the surface would cause a greater change in the position of the shell due to the sloping wall on which the arbor made contact.

Such change in position might vary considerably with roughly made forgings and cause occasional trouble with thin walls which can be avoided if the shell be positioned with the point of the arbor against the end of the nose. The possible variation in position would now be directly proportional to the irregularities on a small surface which could be inspected both by eye and hand much more effectively than the sloping portion of the nose; the actual point of contact being known, whereas the probable points of contact on the three-point arbor could only be guessed at.

Should it happen, therefore, that operation B1 calls for drilling as scheduled, this can be done quite satisfactorily in any vertical drilling machine of suitable size. In performing this operation, the internal supporting arbor is dispensed with, and the shell placed upright on the base which has just been trimmed. If the drilling be done with ordinary care, the hole will be fairly concentric with the outside surface of the shell, and will run practically true when the shell is chucked as per operation B2, see Fig. 5.

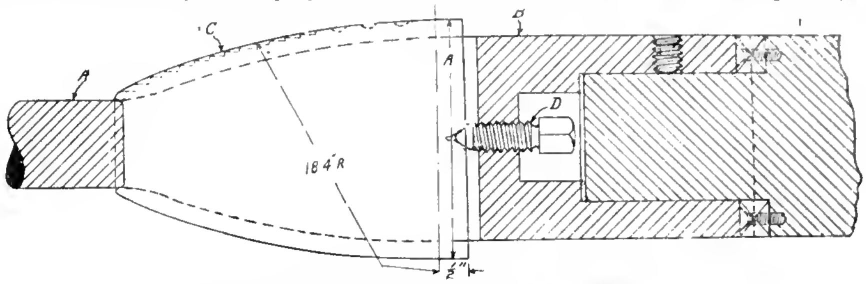

FIG. 6. DETACHABLE BORING HEAD WITH FORMED CUTTER.

The tooling outfit as shown here can be used for every operation which it is advisable to do at this chucking of the shell. The forging shown is the one for the 8 in. shell, and as many makers will be utilizing existing machines, the belt power will probably not be sufficient for pulling simultaneously all the cuts which it is possible to arrange. The work, therefore, is arranged more in accordance with such methods as obtain in general machine shop practice.

The boring bars are fitted to a simple form of revolving tool box or turret, which should be accurately located to line up the bars with the spindle, and securely fastened in place. A quick acting and rigid clamping device is essential.

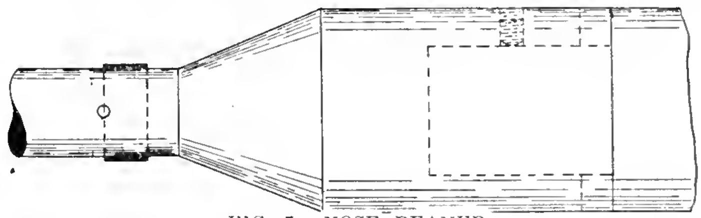

FIG. 7. NOSE REAMER.

The boring bar shown in operation is made as large as possible, while leaving sufficient space for cuttings to pass freely. One slot only is shown, and a set of interchangeable double edge cutters is used. These cutters are checked in on the back and held in place by a wedge.

After roughing and finishing the parallel bore, the turret is reversed and the forming cutter, sometimes termed arch, acorn, or nose reamer, is brought into action. Two cutters of this type are necessary, the roughing ones have serrated edges to facilitate breaking through the scale quickly, and the finisher being

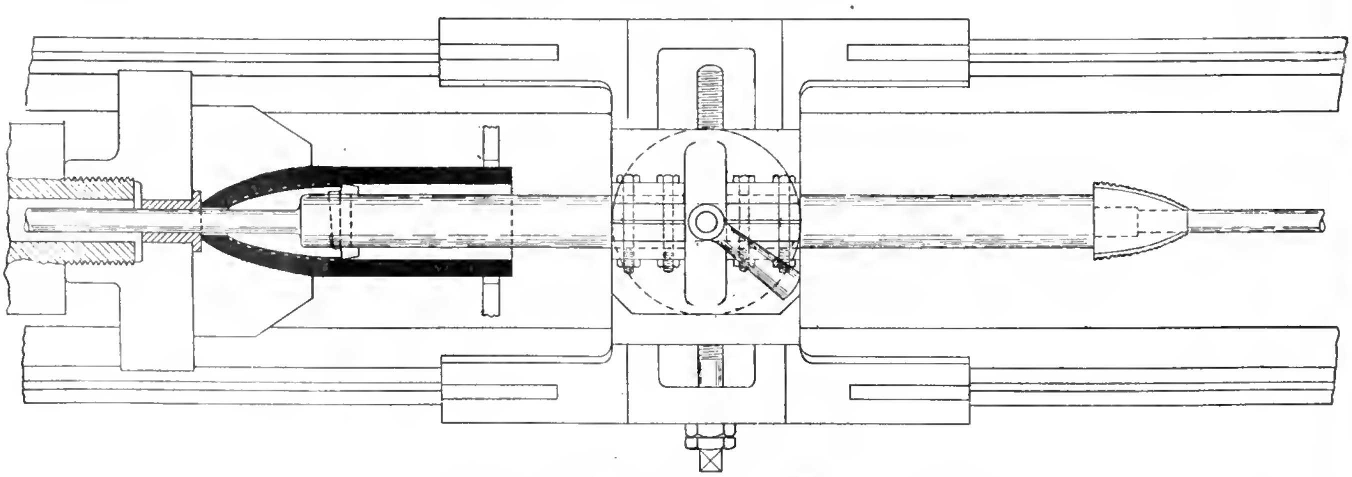

FIG. 5. DIAGRAM ILLUSTRATING OPERATIONS B3, B4, AND B5.

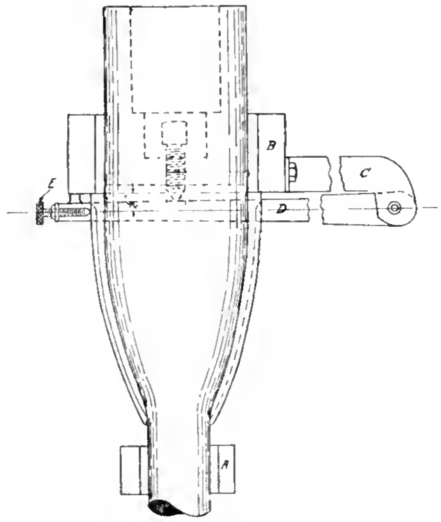
ground exactly to the required curve.

Where tool room facilities are available, and the cutters can be properly hardened, the method of construction preferred may be that in which the cutter is made from solid stock, and grooved like a reamer, with any desired number of cutting edges. First-class workmanship is necessary for the production of this type of cutter, and it must be kept in good condition, and used carefully if costly renewals are to be avoided. It is not quite suited for use with a pilot which is somewhat against its use in ordinary machines. It is used, however, on some special machines having very rigid boring bars.

A type of flat blade cutter is shown in Fig. 6, which has the merit of simplicity of construction, and cheapness of renewal, and permits the use of a pilot if desired. The pilot A, and body B, are made in one piece, a slot being cut to receive cutter C, which is checked at the nose to position it at the pilot end of the slot. The base end is centered to receive the point of set screw D, which is made as large as possible. This set screw is located at the bottom of hole which fits on the reduced point of the bar in the turret. Two driving keys are fitted on the bar and drive the cutter through corresponding slots as shown. A hollow set screw is provided in the cutter body to ensure its withdrawal from the shell.

In making roughing blades for this type of cutter it is satisfactory to file the bottom clearance by hand, but the shape of the serrations or gashes on the cutting edge should receive some consideration so that the height of the ridges left for removal by the finishing cutter is fairly uniform, and excessive wear is not localized on any particular part of the finishing cutter. Reference to Fig. 6 shows a method of determining the serrations. Diameter A is made cylindrical



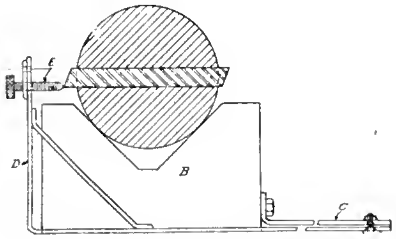


FIG. 8. RADIUS GAUGE FOR INDICATING PROPER CLEARANCE ON FORMED CUTTER.

and three to five thousandths of an inch smaller than the finished parallel bore, so as to act as a pilot on the rear end of the cutter and prevent excessive side strain on the set screw.

The flatter portion of the curve immediately forward of diameter A, may be gashed with a small round file, while further forward the gashes take the shape of saw teeth so proportioned that the short side of the tooth is at right angles to the direction of feed. Suitable clearance must be given to this edge and care must be taken to make the root of the tooth nearer the centre of the bar than the point is. By doing this, the teeth cut with the small edge only and with the greatest efficiency. The dotted lines in Fig. 6 indicate the form of the serrations on both edges of the roughing cutter.

The finishing cutter of course is made exactly to profile called for by drawing. Attention may well be given to the method of forming the bottom clearance on this cutter so that considerable thickness of the blade can be ground away in sharpening without altering the accuracy of the curve. If the blade be mounted in a bar, and given clearance in the ordinary manner with a relieving attachment in a lathe the clearance on the large diameter will be greater than at the point or nose. This is because the plane in which the relieving tool moves is always at right angles to the bar, consequently as the curve of the blade approaches the bar, it is no longer at right angles to the plane of the relieving tools. If the curve of the blade were such that it turned round square across the bar, so as to cut like an ordinary boring cutter, the relieving tool would not give it any clearance at all.

To form this clearance by machinery would call for more complicated mechanism than is desirable. It can easily be done by hand and checked up by a gauge as shown in Fig. 8. The machining arbor is supported on suitable vee blocks A and B. Attached to the larger block B, is an extension C, which supports the radius arm D. This radius arm is made equal in length to the radius called for on the finished shell, and the point on which it swings is coincident with the centre from which that radius is struck. The end of the arm is turned up towards the curved edge of the cutter and has two holes tapped level with the upper and lower edges of the cutter. An indicating screw E, adjusted in either of the holes will show any deviation from the true curve, and the desired amount of clearance can be given by hand and checked up accurately by using the indicating screw in the upper hole. A suitable centre should be provided in the hinge pin of the radius arm so as to set the indicating screw accurately.

As shown in Fig. 5 the nose of the shell is butted up against a gauge stop on the chuck so that boring cuts can be made to certain definite depths to be determined by experiment. The bushing which is used for this purpose can be made with a slight counterbore to clear the final reaming cutter which passes through the nose to size the hole for tapping. This reamer is used on the second

OPERATION TABLE.

Operation Number	Description.
	Group A.
1	Grind off scale on point, forming small flat.
2	Place on expanding arbor which locates shell from inside, and positions it lengthwise from inside of nose.
3	Face-off nose of shell to necessary thickness.
4	Drill centre with drill in tail stock, remove drill and adjust dead centre.
5	Rough turn body, commencing at nose and traveling to point where open end of shell is cut on.
6	Cut off open end of shell to length measured from nose.
	Group B.
1	Drill hole in nose, leaving stock for final boring.
2	Chuck by nose with outer end in steady. Nose of shell in contact with gauge stop on chuck.
3	Bore parallel portion with roughing and finishing cutters.
4	Form interior of nose or arch.
5	Finish overall length and counterbore. Tap base.
	Group C.
1	Tap nose.
2	Insert threaded driving plug centre in base, and common threaded plug centre in nose.

bar and is interchangeable with the forming cutters just described.

The counterbore into which the flange of the base plug fits is formed by a cutter which is located in a suitable position on either of the bars. By making this cutter of suitable shape it faces off the end to accurate overall length at the same time, after which the shell is ready for tapping.

The thread which is formed in the base of the shell to receive the base plug must be perfect so far as finish is concerned, the actual limits of variation in size being easily maintained, and not presenting such a problem as the production of perfect pitch, circularity, and smoothness of surface. The use of a thread milling machine followed by a tap, preferably collapsing, offers the most reliable and accurate method of threading. While tap makers may produce taps suitable for these large diameters, the necessity of terminating the thread close to a given point, throws undue work on the leading teeth of the dies.

Attempts to produce the work at the necessary rate on an engine lathe would spoil an undesirable percentage of the work, unless first-class skilled labor and accurate machines were used. It would, therefore, seem wise to make haste slowly and surely regarding this one operation. At all events it will be found best to do this work in a specially equipped machine with reliable help. The completion of this operation finishes group B.

INDICATIONS OF A STEEL FAMINE

INDICATIONS are not wanting that if there is a continuance of the demand for steel for the manufacture of munitions throughout another year or so there will be a general steel famine—a famine which will be severely felt in this country. The most outstanding indication of this is to be found in the action of the United States Steel Corporation, which was referred to in these columns recently. The situation has shown no improvement since, but rather the contrary; the big American company continues its attitude, which is that prices have been withdrawn on all export business.

Canadian officials of the company have little to say further than that the demand for steel has been such that until the future is more clearly defined no more foreign orders will be accepted. It is not so much an indication that Canada may be indefinitely cut off from her American supplies, but the fact that U. S. Steel is forced to take such action is a startling revelation of the position of the whole market.

Munitions Demand the Chief Cause

At the present time the chief feature of the steel trade is the munitions business, especially in Canada. In the United States, as in this country, there has been heavy consumption for shells, and, on the other side of the line, this has been followed by a heavy domestic demand, in which the railroads have played a prominent part. This has had the effect of piling up orders for many months in advance .

The situation as regards munitions in Canada does not appear to be directly affected by the cutting off of American steel. In other words, supplies of steel for munitions manufacture have been booked months ahead by the Shell Committee. So far as munitions are concerned, then, the question is one largely of the future, but it undoubtedly creates a problem in connection with any orders that the Shell Committee may have in hand for which they have not booked steel and for orders to be placed in the future.

The Domestic Situation

The domestic situation as regards steel products is more directly affected. It is doubtful if such an upheaval has ever occurred in the metal trades in this country as that brought about by the withdrawal of American prices. On wire, sheets, boiler plates, tubes, and many other lines, not to mention the higher manufactures of the metal, there are indications that the famine may not be long delayed if there is no relief offered—and there appears to be none in sight. Metal merchants state that they are not only told that there are no quotations, but the intimation is that their business is not wanted and propositions do not receive consideration.

This is a particularly difficult problem with the great bulk of Canadian steel being devoted to the manufacture of munitions, because we have become more dependent upon the American producers for the special products. The result is that, with the prospects of a future shortage, prices are being rapidly advanced on the many lines directly affected, and the outlook is for rising prices until such time as there is some definite assurance of supplies. If there should at this time arise a domestic movement similar to that in the United States the famine would almost immediately become an actual fact.—Financial Post.

New Zealand Scheelite.—A New Zealand lady has offered the Government the gift of a deposit of scheelite—an ore yielding tungsten, used in hardening of steel—containing 30,000 tons, now worth £631 per ton. The deposit, discovered in the Marlborough district of New Zealand several years ago, consists of three reefs, over which she holds the mineral rights. The offer is conditional upon all moneys received being paid over to wounded soldiers.

WHAT ARE MONITORS?

THE bombardments of the Belgian coast, carried out by a squadron under the command of Admiral Bacon, claim our attention.

To commence with, General French has let us into the secret of the important naval post to which Admiral Bacon was appointed. This officer will be remembered because of his association with the submarine service in its early stages, as a member of the committee which approved of the Dreadnought design, and as the first captain of the Dreadnought. When war broke out, Admiral Bacon was connected with the Coventry Ordnance Works, and some criticism was passed on the appointment of a retired officer in preference to the rear-admirals still on the active list.

Some years ago the Germans carried out a series of experiments with the view of testing the efficacy of concealed shore batteries against ironclads, and the conclusion was reached that no country would risk her fighting ships in an attack on a defended coast.

After the first surprise attack on the Belgian coast by Admiral Hood's squadron, the enemy immediately studded the coast with batteries. No doubt they hoped that this would act as a deterrent to further attempts by our ships, but they had reckoned without the skill of our naval authorities.

Vessel Features

The outstanding features of these vessels, which as a class are named after Ericsson's first "monitor," are shallow draught, small freeboard, low speed, heavy armament, and fairly efficient protection. The shallow draught renders them capable of working in shallow water, and this is an advantage in two ways: it permits of their working close inshore and in waters too shallow for a submarine to manoeuvre in without running suicidal risks. The shallow draught also means a small underwater target, which compensates for the lack of defensive qualities incidental to the slow speed.

The low freeboard makes these vessels a very small target for the land gunners. Briefly, the monitor represents the maximum hitting power carried in the smallest possible space, big offensive qualities in a small target.

These little vessels have overcome the elaborate plans of the enemy for the defence of the coast. They are the best possible reply to the enemy's move, and they show that, in spite of all that is urged against our administrators, we do possess men capable of finding the flaw in the enemy's plans, and resourceful enough to develop the means of profiting by their discovery.—Liverpool Journal of Commerce.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

FLAT SURFACE GRINDING MACHINE FOR SHELL WORK

THE remarkable efficiency shown by disc grinders on shell work has led to their rapid adoption by numerous munitions factories in all parts of the world. As a result of this widespread use of their machines, Charles H. Besly & Co., 120F North Clinton Street, Chicago, U.S.A., have been enabled to incorporate many new and efficient features which make this machine invaluable to makers of shells up to 4.72 in., or 120 mm. diameter.

The Besly shell grinder is illustrated in Fig. 1, with water hoods and piping removed to show construction. This shows the machine equipped with work-holders for removing stub ends left for centres on 3-in. shrapnel shells. Stub ends, 5/8 in. diameter by 3/8 in. long, are removed, and end of shell finished flat, smooth and square at the rate of 100 shells per hour per operator. The geared lever feed table on the grinder carries an adjustable micrometer stop screw, bringing the work accurately to length (if required) and duplicating.

The grinder spindle is driven by a 7-in. belt running 4,000 feet per minute, so ample driving power is provided. The grinding is done by vitrified ring wheels held in pressed steel chuck. It should be noted that as the grinding wheel wears away, it may be set out in the chuck as required. The ring wheels are 16 in. diameter, 4 in. deep when new, and may be worn down to 1 in. in depth before being discarded.

Fig. 2 shows the Besly shell grinder equipped with rotary chucks for accurately finishing the inner face of base plates or gas plugs for high explosive shells. The action of the grinding wheel rotates the work while grinding, producing work of extreme accuracy in flatness and angularity. Many munitions manufacturers have had trouble trying to produce base plates or gas plugs with the inner face flat and accurately at right angles to the axis of the thread on the plug. This plug is a difficult thing to hold rigidly enough to thread accurately and face flat and square. The Besly shell grinder with rotary chucks, as illustrated in Fig. 2, overcomes this difficulty, because in the facing operation the plug is chucked from the threads. When required, this face may be ground with a camber of .002 in. to insure contact all over.

This special rotary chuck is also used with unthreaded, beveled jaws for grinding the unthreaded beveled base plates or gas plugs, now being used by a great many manufacturers of high explosive shells.

The time for this grinding operation is 60 to 80 gas plugs per hour, per operator, depending on the amount of stock to be removed.

These grinders are also supplied with work-holders for facing the end of 4.5 in. and smaller high explosive shells after base plate or gas plug has been inserted in shell, and the square projection on base plate removed by sawing, twisting or grinding. Where gas plugs are threaded, the square projections are usually twisted off after the plugs are screwed home in the base of shell. Where the unthreaded, beveled gas plugs are used, this square projection is usually sawed off in power saw, although it is entirely practical to remove same by grinding.

After the square is removed, there is up to 1/16 in. of stock to be removed from the rear face of the gas plug (3 3/8 in. diameter) to bring same flush with base of shell. This grinding is accomplished on the shell grinder at the rate of 15 to 40 shells per hour, per operator, depending upon the amount of stock to be removed.

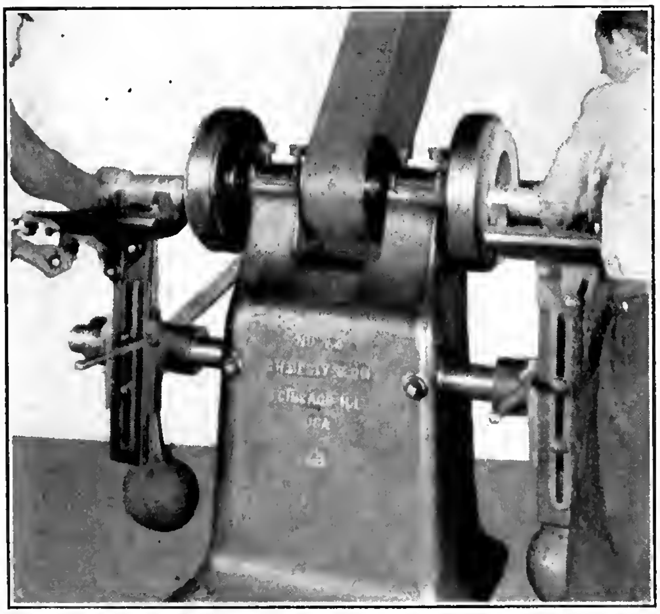

FIG. 1. GRINDER WITH WATER HOODS AND PIPING REMOVED.

FIG. 2. GRINDER SHOWN EQUIPPED WITH ROTARY CHUCKS AND HOODS.

In connection with the water hoods, there are a pump and settling tank of 40-gallon capacity, with suitable settling compartments to extract the grindings from the cooling compound.

An exclusive feature on this machine is the provision of a geared lever feed on the table, providing a leverage of 26 to 1, making it easy for the operator to force the grinder to the limit of its capacity.

All wearing parts are renewable and adjustable for wear. The machine weighs over 3,000 pounds. The spindle is 2 in. diameter, and has a total bearing length of 18 in., the end thrust being taken on hardened and ground thrust bearings.

Papers Read at the Recent Foundrymen's Convention

Selected from the more important subjects presented for discussion before the Annual Convention of the American Foundrymen's Association and the American Institute of Metals at Atlantic City, N.J., during September, 1915. The papers cover a wide field of foundry and allied activity, the nature of the results and the completeness of the reports making them of particular interest to all who desire to keep in touch with metallurgical progress.

ESSENTIAL ELEMENTS OF SHERARDIZING*

By S. Trood

BEFORE going into the description of sherardizing, it is well to mention something about zinc.

Zinc is a peculiar metal of pronounced characteristics. It is relatively low in malleability, ductility, tenacity and fusibility when compared with other common metals. Zinc has a melting point of 419 deg. C. and under atmospheric pressure a boiling point of 918 deg. C. While under vacuum, the boiling point is reduced to 548 deg. C. On the basis of silver at 100, zinc has an electrical conductivity of 29, a heat conductivity of 36, and is practically non-corrosive in the atmosphere, a thin protecting coating of carbonate of zinc forming upon it. Zinc is one of the highest electropositive metals, having a potential of plus 0.493 volts.

Although many of the common metals date their discovery to prehistoric times, yet zinc was unknown as a metal until discovered by Paracelus in 1520. Previous to this, however, the action of zinc ores upon copper under action of heat was well known. Henchel in 1271 published an account of his discovery that metals when heated in calamine changed their properties, and in 1740, John Champion, of Bristol, England, obtained a patent for the process. Two of the processes of smelting zinc to-day date back to 1805 for the Belgian process and 1897 for the Sicilian process. In the United States, the Government was the first to use zinc, making the standard of weight and measure from brass.

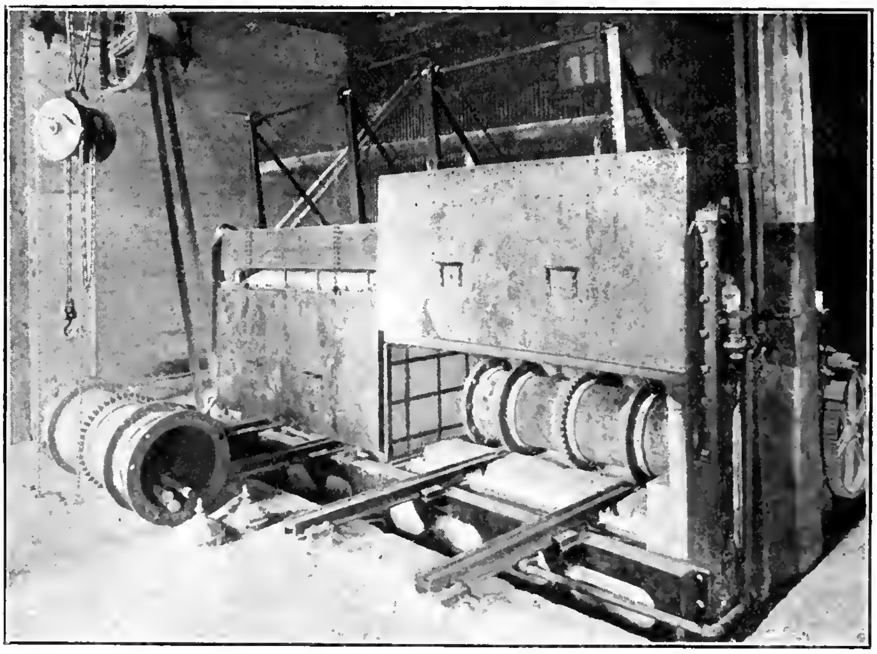
It has only been within the last century that zinc has been used commercially as a protection against corrosion, and as a proof that the tendency of using zinc is toward the conservation of natural resources, it will be seen that by comparing the production of zinc and steel for the last four decades, the large increase in each has been running parallel for the corresponding years.

Process Features

In general, the process of sherardizing consists in treating in zinc dust, articles which it is desired to rust-proof. The zinc dust consists mainly of finely powdered metallic zinc with zinc oxide. After packing in a suitable container, the whole is heated for a certain period of time, cooled and articles then removed from the zinc dust. From everyday practice, we note that if we desire uniform results in a manufacturing proposition, we must have uniformly arranged details. So far as the sherardizing is concerned, the uniformity of each step in the process is very vital and necessary for success. In trying to explain what happens in the drum, the necessity of uniformity will explain itself.

Zinc dust is in a very finely divided state, and each particle covered with zinc oxide. In this condition, zinc could be heated above the melting point without fear of liquefying the mass, and because the zinc oxide is quite high fire-resisting material of inert nature, it prevents small particles of heated zinc uniting together and creating a solid liquid mass. It is also a well-established fact that under these conditions solid matter can be made to sublime; in other words, a solid can be brought to a vapor, overstepping the liquid form.

According to authorities, vapor tension for a small particle is greater than vapor tension for a big body, due to the difference in the ratio between surface and volume. Armstrong, Thompson, and other scientists have shown that a gas emanated from a solid has an electrical charge. From this, it follows that the microscopically small atmospheres of zinc vapor surrounding these dust particles are charged electrically, and due to their minute size, they may be considered to have all the properties of ions. Iron being heated, also emanates gases which produce ionic charges. Iron and zinc have different electrical potentials, and, therefore, the ionic charges of zinc and iron vapors will have a different potential. If this is a fact, then discharges must occur. Ionic discharges precipitate solids from gases, and in our case zinc and traces of iron would be precipitated.



TWO COMPARTMENT SHERARDISING FURNACE, TAKING 18 IN. X 60 IN. DRUM, INSTALLED IN PLANT OF CHAMBERS, LTD., TORONTO. THE FURNACE IS ARRANGED TO HANDLE MATERIAL UP TO 11 FT. 6 IN. LONG.

Atmospheric Effect

Assuming once more that the theory is correct, the atmospheric pressure will have considerable effect on the process, as the vapor tension of gases will vary with the pressure, and the gases will be more readily emanated in vacuum. If we make use of a considerable vacuum, for instance, 28 ins. of mercury, the ionic discharge would be very effective. To prove this, I created a vacuum in a small sherardizing drum. In this case, the precipitation of zinc and iron took place at a much lower temperature and in considerably shorter time. Results were produced in ten minutes in a vacuum, which would require six hours at the same temperature, but under atmospheric pressure.

*From a paper read at the American Institute of Metals Convention, held in Atlantic City, N.J.

It is a well known fact that the electric potential is higher for pure gas than for a mixture of gases. Therefore it is quite advantageous to have pure zinc dust and the iron in as pure a state as possible. As before stated, zinc is one of the metals which has the lowest difference in temperature between melting and boiling point, and this difference is quite low under vacuum. This is another proof that, with pure zinc dust under vacuum, the vapors will be created much more readily, ionically charged and precipitate the solids upon the surface.

Zinc Dust and Heat Factors

From the above, we can draw the conclusion that uniformity of zinc dust is a very important factor. Uniformity of heat, however, is of just the same importance, since the higher the temperature, the greater is the emanation of gases and, therefore, precipitation of solids. This may be seen on sherardized metal in the typical "color lines."

With every increase of temperature, with all conditions the same, the precipitation of solids increases and creates a deposit of a different character, and the same is true with a decrease in temperature, which retards the process and creates a less dense coating. These differences, which produce the stratified appearance or lines of color, are quite distinct under a microscope and may explain the very fine microscopic checks. That the quality of iron to be sherardized has a similar effect on the process can also be readily understood, as emanation of gases from iron depends greatly upon its composition. Particles imbedded or stuck on the surface may also change the potential.

The last great factor in the process is time. It is self-evident that the effect of precipitation will continue so long as the conditions are favorable to create the effect. To repeat:—1st, composition and quality of the surface of the iron; 2nd, composition and uniformity of zinc dust; 3rd, proper uniform temperature; 4th, time, are the most essential factors in the process of sherardizing. The practical side of sherardizing depends solely upon the four factors just mentioned. Sherardizing is mostly applied to steel and iron in all its forms. Articles which could not be heated, should not be sherardized. All material should be examined and rejected if it is scaly, covered with silica or any other impurities.

Preparing Surfaces for Sherardizing

The best method of removing the impurities—in other words, preparing the surfaces to be sherardized—is shot air blasting. This method is fundamentally the best, because in sand blasting particles of sand or silica penetrate the pores of the iron and are very disadvantageous. Pickling requires great skill and must be done very carefully, as very often sulphates or phosphates are created on the surface, and if washed in alkalies, very often go into colloidal state. In other words, they become insoluble and very hard to remove. Another disadvantage of pickling is that the traces of salts, alkalies or acids when heated, may produce a retarding result so far as the ionic charges are concerned.

There are different zinc dusts on the market and those coming within the following limits would be the most advantageous:

Zinc between 85% and 90%.
Zinc oxide between 8% and 10%.
Lead between 1% and 1.5%.
Other impurities between .5% and 1%.

The three most important elements to be kept near the above percentages are:

Zinc which ought not to be below 85%.
Zinc oxide which ought not to be below 8%.
Lead which ought to be kept down to about 1.25%.

Although good sherardizing may be obtained if some variations from the above exist, the best results will be obtained if the percentages are kept within these limits. Lead must be kept down to the least practical amount, as experiments have shown that, when its percentage runs too high, lumpy deposits will appear on the sherardized plain surface and will also clog threads.

Free iron must be separated from the zinc dust as much as practice will allow, and in a well-established plant it is being done at least once in four weeks. This will remove surplus small particles of iron; which are liable to become lodged between the jaws or cotter pins, etc., and thus cause trouble in assembly. By cleaning the dust this way, the mechanical incorporation of small percentages of iron dust in the coating is also prevented. The weekly analysis of the working dust should show the iron content.

It was mentioned above that the size of particle has an effect on a vapor tension. Therefore, zinc dust must be kept uniform in size. When the zinc becomes caked or lumpy, it should be run through a tumbling barrel and sifted through at least 80-mesh screen. To keep practically the same metallic content, it is necessary to add to every charge, between 8% to 10% of virgin zinc dust. Weekly analysis of zinc dust should be made and the samples taken from the working zinc dust which has been sifted and well mixed together in one or several sherardizing drums.

In the question of temperature, it should be understood that there is practically no limitation. If a very long time for the process is allowed, low temperature could be used, but this is not practical and, therefore, a higher temperature will have to be reached. Also, the drums or containers are of metal and a working temperature must be of such a degree as not to destroy the working of the apparatus. In one case the temperature would be quite high and in another case it would be quite low.

Apparatus Feature

Any practical apparatus which would keep a uniform temperature throughout, would be advantageous, and, in this respect, the electrically heated drum would be the more suitable, as here the control of the heat as to uniformity, time and degree is ideal, and when electrical apparatus is used, 350 to 375° C. would be the most suitable temperature, as within this range a very practical and serviceable apparatus can be designed. There are some successful installations where gas as a means of heat is employed, and here the drums are passing through a continuous tunnel oven going gradually from the cold to the hottest zone and then to the cold.

The size of the container and construction have very much to do with uniformity of heat, as, if the dimensions are large, longer time is required to heat the apparatus. Zinc dust is a very poor conductor of heat and articles hardly touching each other do not offer a good path for heat.

Continuous rotation of the drums eliminates to a certain extent those disadvantages, since it produces a uniform mixing of the contents of the drum and allows the more heated particles on the outside to convect the heat to the centre. Packing the drum too tight will prevent a free flow of dust and heat, and consequently different temperature zones will occur with resulting different degrees of deposit.

Thickness of Deposit

After deposit of zinc begins, with all other factors well established, the thickness of the deposit depends solely upon the time. All other factors being constant, a good coating depends upon time, and if the process is continued too long, a brittle and easily chipped coating will result. This is due to the wide difference in co-efficient of expansion and contraction between the zinc and iron, which have co-efficients of .00002532 and .00001166 per degree centigrade, respectively.

The coating which is being deposited when the temperature is going up is the most dense and durable; next in quality will be the coating of the uniform temperature period and the least when the temperature is going down. If small articles are treated where sharp profiles and threads are present, the time element is most vital. It is very hard to establish

any certainty in the time element, but in every case it has to be established in accordance with other factors.

The relation of these vital factors to the process of sherardizing is such that each one is dependent on the other, with the result that the variation of the one will require a variation of the others. Therefore, in order to simplify the process and make it practical on a manufacturing basis, it is found that uniformity is the essential element. This is practically all that need be said on sherardizing, although much could be written on sherardizing for special conditions.

I have come in contact with practically every large sherardizing plant in the United States, and, with very few exceptions, they still have some trouble with the process. After analyzing the troubles, I found that the uniformity and relation of these factors was not properly maintained.

I know at least one concern which—by using shot air blasting; very uniform and high metallic content zinc dust, which is periodically cleaned and magnetically separated and sifted; which uses electrically heated drums of proper design, giving a controllable uniform temperature—obtain very desirable results on sherardizing. The purpose of this paper, however, is not to describe the everyday methods of sherardizing, but to point out the essential elements of the process.

The next step in sherardizing will be a continuous method in vacuum, for by this method, the narrow margins of the atmospheric pressure process will be broadened and more uniform results with less effort will be obtained.

CANADA WILL NOT MAKE BIG GUNS

IT is understood that Canada will not have a big gun industry just yet. The Imperial Government has decided not to proceed with the establishment of a plant for the manufacture of heavy artillery in Canada, for the present at least. Word was received in Ottawa recently to that effect.

At a conference which took place some weeks ago between military officials here and representative Canadian manufacturers and financiers, the question of constructing heavy guns was discussed and the opinion of the conference was that such an undertaking was feasible. Although it was never so stated officially, it is known that this opinion was confirmed subsequently by Sir Frederick Donaldson and General Mahon, who came to Canada to look over the ground at the instance of the War Office. These experts visited the various steel plants of Eastern Canada and conducted a thorough investigation into the resources which could be drawn upon for the construction of heavy guns. They returned to England on the completion of this investigation and are understood to have reported favorably upon the proposal to establish a big gun industry on a moderate scale.

The Imperial Government's reason in coming to an adverse decision is not known, although the question of time may have been one of the chief considerations. It has been stated that a Canadian artillery plant could not do very much in the way of output inside of six months. The establishment of such an industry would have meant a distribution of orders amounting to many millions, the proposal having been to have the parts manufactured at various points and assembled at one or two large plants in the East. Although the decision of the War Office does not preclude a renewal of the proposal at some future time, it is considered here to be unlikely that any further steps will be taken. It is pointed out, however, that there is plenty of work to be done in the production of shells and other munitions.

EFFECTIVE FORCE BETWEEN DRIVING BELT AND PULLEY

THE law of friction of solid bodies applies fully only to the case of surfaces of belts and pulleys clean and absolutely free of grease, and the nearest approximation is the case of new belts having very little grease on them. If, on the other hand, there clings, more or less perfectly, on the smooth surfaces of the belt and pulleys a thin skin of liquid, then, in accordance with the amount of its adhesion, the magnitude of the effective force varies as the internal friction of the liquid, and thus becomes functionally dependent on all other variables: in particular the effective surface, the gliding velocity, and the temperature and viscosity of the adhering liquid. Under such conditions new forces come into operation, in some cases many times greater than those acting in the case of pure friction between solid bodies. The properties of the belt material become of secondary importance, while the properties and amount of belt grease assume a pre-eminent importance.

Belt Grease Importance

The presence of a uniformly thin and smooth skin of grease on the gliding surface of a belt has a double effect. In the first place, it makes possible the rise of large forces between belt and pulley, especially with increase in gliding velocity. Second, it protects the surface of the belt. In particular, for high belt velocities, belts should be as flexible, soft and well greased as possible. In the case of a slightly greased belt, the application of a proper belt grease to the clean surface can help in building up a thin skin of grease between the belt and the smooth pulley which raises the effective forces as has been proved by experiments.

When there is a skin of liquid present, the magnitude of the effective forces increases, in the first place, with the gliding velocity. This makes the belt drive stable as regards overloads (up to certain definite limits of this latter); when large peripheral forces have to be transferred, higher gliding velocities must be used, and they lead to increased frictional resistances on the assumption that the temperature remains permanently constant. The average gliding velocity of the belt and pulley increases (all other conditions being the same and peripheral forces transferred being equal), approximately in proportion to the belt speed. In the high speed belts, therefore, usually larger frictional forces are in operation.

The superiority of large pulley diameters and comparatively wide belts, established by experiments, is partly explained by the functional dependence existing, in the case of well-greased belts, between the magnitude of the effective forces and that of the gliding surfaces.

With rough surfaces of pulleys the effective force is greater than with the smooth pulleys only when the velocity of gliding is negligibly small. Otherwise it is always smaller, the more so the more perfectly the face of the belt is covered by a thin skin of fluid. As a result rough pulleys not only cut down the life of the belt through increased wear, but they do not accomplish the purpose of increasing the frictional resistance in gliding.—Page's Weekly.

COLLINGWOOD SHIPBUILDING CO.

CONSIDERABLE activity is likely to be seen during the coming winter at the plant of the Collingwood Shipbuilding Co., Collingwood, Ont., not only in the production of new vessels, but in the matter of general repairs as well. Construction is approaching an advanced stage on the two vessels for the Imperial Oil Co., and as briefly noted in another section of this issue, an order has been secured for a large freighter, particulars of which are as follows: Length, 550 ft.; beam, 58 ft.; depth, molded, 31 ft.; gross tonnage, about 8,000; deadweight on 19 ft. 6 in. mean draft, 11,000 tons. Three Scotch type boilers each 13 ft. diameter by 11 feet long, will be installed, and the propelling machinery will consist of one set of triple expansion engines. The vessel will be built on the arch principle with deep double bottom and side tanks, the design being such as to enable either grain or coal to be carried

"PLAYING UP" STEEL

THE more or less prevalent inactivity, long drawn out, on every section of a far-flung battle line, and the natural expectation that something big might materialize at any time, appear to have not only unsettled and unnerved our people to an extraordinary degree, but have engendered a disposition in many quarters to "start something" on their own initiative, irrespective of its having foundation on fact, or of the consequences.

We have in large degree got beside ourselves since the manufacture of war munitions became established in our midst. The paucity of orders placed with our manufacturers as compared with those distributed among American concerns; the disposition to keep Canadian contracts within a limited and select circle; the fault-finding with and whisperings of graft on the part of those charged with the administration of our public affairs; the glaring and unrestrained speculation in war stocks, and the giddy heights to which these have attained; the outcry to tax our manufacturers on their war profits, and the hysterical demand for a Minister of Munitions; these as constituting the more outstanding features of recent months may be cited as exemplary of the nervous tension under which we are laboring.

Each of the foregoing has attained to the full fever-heat of passion—in some the temperature excelled—but, in all, the cooling off is now in process. The whirl must needs be kept up, however, and just at the moment "steel" is in the ring, and overshadows all else. The gods of war, we are made believe, have decreed a steel famine, and, to challenge the possibility, no matter how reasonable one's deductions might indicate otherwise, would of course be futile. This steel famine cry has got to run its course, and will do so quite as worthily as its initiation deserves. It is unfortunate, however, that the cry has been raised, and perhaps more so that it has found so many adherents and supporters.

Steel prices covering every description of commodity into which the material enters have advanced to a prodigious extent, and we are quite certain that the limit has not nearly been reached. The demand for war munitions has brought about the extraordinary demand for steel, and the present hue and cry notwithstanding, there is little doubt but that the former will be satisfactorily met by the latter. Steel for structural purposes, outside of shipbuilding, is in but light demand, and that for otherwise and domestic requirements may not easily be assumed urgent. In any case, it is a question of price to be paid by the consumer, and is dependent on the latter's attitude—in war-time just as in peace-time.

A shortage is, we believe, imminent in billets and other forms of semi-finished steel, principally, of course, because of the extraordinary requirements of Britain and her Allies, and secondarlly because the domestic requirements of this North American continent begin again to loom up. Whether, however, the latter will continue to develop to any greater extent in the near future is problematical, in view of the fact that prices are already abnormally high, and give every evidence of reaching still more prohibitive figures.

Already we have reports that several large consumers of semi-finished steel contemplate the early closing down of their plants—at least temporarily. In spite of this, even if the reports have a meantime real foundation, we do not anticipate any such untoward happening. As we stated a few weeks ago, there are limitations to the extent that our big corporations are prepared to go as regards prices of raw and semi-finished steel, and exemplification of this is seen in the decision of the Pennsylvania Railroad System to take no further action meantime regarding the addition of some 11,000 freight cars to its rolling stock which it contemplated.

While agreeing that our domestic requirements may not be neglected, we cannot understand why apparently herculanean efforts should be made to boom them now, except it be to add impetus to the price raising propaganda. This domestic demand, as it is termed, has burst into an altogether too sudden prominence to be reckoned as enduring, and instead of the second quarter of the New Year marking the crucial or famine period, there is not a little possibility that the Allies, through the conservation now being enforced, will have both lessened the demand for munitions' steel from beyond their own borders, but will have materially lessened the market quotations for steel for all purposes everywhere.

We are still of opinion that no real domestic demand for steel will materialize until war prices of that commodity in any form tend downward towards those associated with peace-time activities. We also believe that the war needs of the Allies will be successfully met.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, Nov. 29, 1915.—The closing days of November show continued improvement in the trade conditions that have prevailed for the past few months, and the general feeling is that developments in this direction will be maintained. The exceptional open weather of the past few weeks is responsible for a record being made in the navigation history of the St. Lawrence, the present week being the latest in the history of the river that the gas buoys have been in place for night navigation. The last departure for a sea voyage is scheduled for November 30. Shipping companies have benefited greatly by the extension of harbor closing.

With the closing of navigation, increased activity will be manifest in the operation of the various railway systems, and their full equipment and rolling stock will be requisitioned to handle the transportation of goods to foreign ports.

The activity in the manufacture of supplies for the allied armies continues unabated. Orders have been awarded to manufacturers in this district for 600,000 pairs of shoes, and this may be added to at any time. The capacity of our cotton mills is taxed to the utmost to supply the domestic and army needs. Colored goods are subject to heavy advances, due to the inability to secure the necessary dyes.

Great inconvenience, we understand, is being experienced by Western farmers in certain districts, because the unprecedented crops have overcrowded the available capacity of the grain elevators; in many instances large quantities of bagged grain being stacked in the open field and inadequately protected from weather conditions. Although the C. P. R. are now moving twelve miles of loaded cars per day, the closing of lake navigation tends to make the storage and transportation problems ever present sources of anxiety to our farmers.

The war, while a devastating agent in many respects, has opened the way for a great future for this country. Many lines of industry previously little known in our midst, have developed remarkable proportions. The inability to secure much-needed chemicals (formally imported from Austria and Germany) has given great impetus to their local manufacture, and many plants have been erected and are now working to capacity supplying what a few years ago was deemed impossible.

Public opinion is being and will continue to be educated along stimulating and constructive lines, and with the coming years there are bound to come further unheard-of developments in Canada's industrial position.

Pig Iron

Production of pig iron is being maintained as fast as our blast furnaces can reduce the ore. Further price advances are, of course, expected.

Steel

The abnormal conditions at present prevailing in the steel situation show little variation from the previous week. Contemplated placing of further orders for British, French and Russian shells will not only add activity to the steel producing industries, but will also increase the difficulty of securing an ample supply of steel.

The probability of a shortage in the steel supply is being discussed, and prophesies are that a few plants may be temporarily shut down. Domestic requirements have been greatly affected by the present European situation. For many years the Krupp works in Germany have supplied certain brands of steel in this connection, but with the opening of hostilities this source of supply was suddenly cut off. The manufacture of these particular grades of steel had been given little attention on this continent. The past year has, however, shown great developments in the production of steels previously made in foreign countries, with the result that today this grade of steel has not only been duplicated, but the possibilities are that the improvement will exceed the highest expectations of its producers. Thus, it may be said that, although the war has had terrible results in many ways, the necessity of the times has forced the American and Canadian manufacturers to develop resources that have until now been lying dormant.

Boiler plates have shown strength during the week, and are now quoted at \$2.75; heads, 30 inches and over, \$2.80; and tank plates, \$3.

Sheets are holding firm, with an advance likely in the near future.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion \$100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

Machine Tools and Supplies

Domestic requirements are commencing to add increased pressure to those of the war for machines and equipment. Some machine tool builders, who contemplate making additions to their plants, are uncertain of being able to secure the necessary help to operate same. While this might be true in some localities, the general impression, however, is that sufficient help will be available to maintain any increased output required.

Automobile makers are continually adding to their equipment, and much increased production along these lines is looked for this winter and during the spring of 1916.

The continued demand for supplies to maintain shell production is keeping the prices of these commodities firm and steady. The heavy demand for high-speed steel continues and quotations of \$2.50 upwards are still in force. Prices on all supplies are holding firm.

Metals

The general condition of the metal market shows little change, with the exception of copper and tin. The former, due to increased domestic demand, has advanced, while the latter has dropped below last week's price.

Copper.—The strength of the market this week is due to the increased demand for domestic purposes. However, if the war requirements have a tendency to force the price much higher, the domestic demand may be somewhat curtailed, as the increase in price will undoubtedly effect the consumption for ordinary purposes. The mine production at the present time is large, but this could possibly be increased about 5 per cent. The probability of continued war demands will likely call for a further advance. With the increase noted this week, the quotation on lake copper, carload, is \$21.50 per 100 pounds.

Tin.—Both buyers and sellers are showing little interest in spot or future deliveries, and the market is dull and inactive. Present quotation of \$46 shows a decline of \$2 over the previous week.

Spelter.—Despite foreign firmness in spelter, the local market is quiet. However, the prices are holding steady, and no advance falls to be registered. The consumption is not exceeding the supply, and no price change is expected. The market is steady at \$20.

Lead.—The demand at present is not heavy, and the market is not active. The quotation of \$6.75 prevails.

Aluminum.—No change is shown in aluminum, and the market is firm at 62c per pound.

Antimony.—This is firm, 42c being quoted.

Old Materials

The remarkable activity in the scrap metal market during the past week has created much excitement among dealers. Trading in old material of every description is general, and prices have advanced in every direction. While heavy melting steel scrap has shown no advance, the possibilities are that future quotations will show an increase. The stiffening of all grades of scrap is a feature of this week's business.

Toronto, Ont., Nov. 30.—An interesting development affecting the steel industry is the announcement that plans are being worked out for extending the scope of the Munitions Committee to include the distribution of orders for shells from all the Allies. Another interesting feature is a proposal for Canadian banks to assist factories in financing orders for shells. An arrangement such as this will permit of larger orders being handled and greatly simplify the financial aspect of the business. Hitherto all payments have been made in British funds. No very definite information is available with regard to the 8-in. and 9.2-in. shells, but it is understood that orders for 60-pdr. and 6-in. shells are being placed first.

The reorganization of the Shell Committee has been completed and the new body will be known as the Imperial Munitions Board. J. W. Flavelle of this city has been appointed chairman, and General Alex. Bertram deputy-chairman. A Commission has been appointed to enquire into the supply of raw materials for the production of munitions. Col. Thomas Cantley will be Chairman of the Commission.

Industrial conditions continue to steadily improve and a more optimistic feeling prevails in business circles with regard to the outlook for the future. Money is circulating more freely, railway earnings are increasing, and the volume of business is growing notwithstanding a steady advance in prices of many lines. The volume of exports is also increasing each month, thus improving the financial condition of the country.

Steel Market

The market continues very active and prices are holding very firm with a decided upward tendency. The demand for steel, particularly for shells, is on the increase, and mills are getting behind on deliveries, notwithstanding plant extensions which have been made to cope with the business. Steel bars are firm at 2.75c and iron bars are unchanged at 2.50c, but an advance is looked for in the near future. Wire nails have advanced again and are now quoted at $2.75 base, per keg. Boiler plates and lapwelded boiler tubes are higher. A new list for bolts and nuts has been issued, the prices showing a slight increase over the previous list. A new discount of 25 per cent. for cold drawn steel shafting is announced. Prices of proof coil chain and electric weld chain have been revised. The new discount on iron rivets 7-16-in. and less is 67½ per cent., and copper wire is now 30 per cent. off list. Smooth steel wire has advanced and is now quoted at $2.85 base.

The galvanized sheet market is extremely irregular. There is an increasing scarcity of steel and black sheets are therefore rising in price. Spelter is being maintained at a level too high to be attractive to the makers of galvanized sheets; in addition there is a shortage of sulphuric acid. This combination of circumstances is affecting the market and prices of sheets cannot help but advance. "Apollo," 10¾ oz., are now quoted at $5.75, and "Premier" No. 28, at $5.50. In some cases, sellers have done away with the regular differentials and are basing prices for each gauge on its cost. Some mills are said to be refusing to quote on galvanized sheets on account of operations having been cut down due to the acid and spelter situations. Black sheets are quoted at 2.40c to 2.75c Pittsburgh, and blue annealed 2.10c to 2.25c Pittsburgh.

In the States there is no cessation in the demand, which on nearly all lines of steel products, is beyond the capacity of the mills to supply. The majority of steel companies have sold their output for the first quarter of 1916 and have enquiries extending into the second quarter. Some authorities believe that prices have reached a danger point and any further advances should be prevented if possible. There is little indication, however, that prices have reached the top level. It is reported from London that the Allies can now manufacture all the munitions they require. Even if this is the case they will still need steel, as the output of steel has not increased in the same proportion as munitions. Heavy tonnages of steel will be required for other purposes. Prices continue to advance in many steel products; steel bars, however, are unchanged at 1.70c. Beams are higher at 1.70c, Bessemer billets $28, open-hearth billets $29, and forging billets $50 base, Pittsburg. Prices of billets are nominal owing to the shortage in Bessemer and open-hearth steel.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Messrs. S. Ruperti and Alexsieff, care Military Atache, Russian Embassy, Washington, D.C.

Pig Iron

The market is very active and prices of domestic brands of pig iron have again been advanced; Hamilton and Victoria brands are $1.25 higher than last week and are now quoted at $23 ton. Grey forge, Pittsburgh, has advanced and is quoted at $16.45. There is a heavy demand for steel-making grades of iron, but foundry iron is less active.

Old Materials

Conditions in the market for old materials are much the same as last week and prices are practically unchanged, although firmer for some scraps. Copper and zinc scrap are both very firm and have a higher tendency. Heavy melting steel is strong but No. 1 wrought iron is weaker, and is now quoted at $9. Copper and heavy melting steel are in good demand but other lines are quiet.

Machine Tools

Business has been fairly good in machine tools this week but it is expected that there will be heavier demand later when the large orders contemplated are placed. A number of orders for machinery for the 6-in. and 60-pdr. shells have been booked, but nothing has been done as yet with regard to equipment for the large shells. There is a good demand for second-hand tools, but these are getting somewhat scarce. Prices are still high and deliveries do not show much improvement. An interesting development in the trade of recent date is the taking over of the Russell Motor Car plant by the Willys-Overland Co. It is stated that extensions will be made to increase the output.

Supplies

An advance of 2c per gallon for gasoline and benzine are the only price changes to note this week. There is a great scarcity of gasoline on account of heavy shipments from the States to Europe owing to some of the larger fields being in enemy countries. Turpen-

tine is very firm and may go higher. Linseed oil is unchanged, but prices are irregular. Business continues very active with a good demand for most lines. Prices on high-speed twist drills are still withdrawn.

Metals

The situation in the metal market shows no appreciable change from last week. Copper continues strong and has advanced slightly. The tin market has reacted and is lower, following a decline in London. The spelter market is quiet and unchanged. Zinc ore is very high, being quoted $100 to $115 at Joplin, Mo. The lead market is very strong both in London and New York. The antimony market is strong and scarcity of supplies is being felt. Aluminum is also scarce and quotations are nominal.

Tin.—The market is dull and featureless with prices lower. There continues to be little interest shown by buyers for any deliveries, at the same time sellers are inclined to be indifferent. Tin has declined 2c and is being quoted at 46c per pound.

Copper.—The market is strong and higher and the position of copper is a decidedly strong one. Consumption is increasing and is, if anything, in excess of the current output. Lake copper is now quoted at 20¾c and electrolytic at 20½c per pound.

Spelter. — The market advanced in London. but this did not stimulate the New York market. The situation is practically unchanged and indications point to higher prices rather than otherwise. Spelter is unchanged at 21c per pound.

Lead.—Both London and New York markets are very strong. The "Trust" price of 5.25c New York is being firmly held with a possibility of an advance. Lead is unchanged locally at 7c per pound.

Antimony.—The market is in a stronger position than it has been and is feeling the full effects of the scarcity of supplies. Quotations locally are firm but unchanged at 40c per pound.

Aluminum.—There is no improvement in the situation with regard to supplies. which are very difficult to obtain. Quotations are nominal at 65c per pound.

IMPERIAL MUNITIONS BOARD CONSTITUTED

ADVICES from Ottawa give particulars of the constitution of what will in future be known as "The Imperial Munitions Board." This body displaces the Dominion Shell Committee in the management and distribution of contracts for the various munitions requirements of the Imperial Government. The reconstructed board has at its head J. W. Flavelle, of Toronto, who will act as chairman, with executive and administrative powers. Brig.-Gen. Bertram, former head of the Shell Committee, will in future hold the position of deputy chairman, with the following others comprising the board:—Hon. Col. David Carnegie (member of the Shell Committee), G. H. Dawson, C. B. Gordon, J. A. Vaillancourt and E. R. Wood, the latter four being new members.

The new chairman is head of the William Davies Packing Co., and was appointed a member of the recently-formed Dominion Economic Commission. Mr. Gordon is head of the Dominion Textile Co. Mr. Vaillancourt is president of the Bank of Hochelaga. Mr. Dawson is now a resident of Victoria, B.C. Mr. Wood is a well-known Toronto financier, and is closely connected with the Mackenzie & Mann interests. Mr. Gordon is a well-known Montreal manufacturer. Sir Sam Hughes becomes honorary president of the board.

Commission on Raw Materials

In addition to the forming of the above new board, a commission has been established to make inquiry into the supply and sufficiency of raw materials in Canada required for the production of munitions of war, and as to the best methods of conserving same. The following are the members of this new commission: Col. Thomas Cantley, head of the Nova Scotia Steel & Coal Co., New Glasgow; E. Carnegie, Welland; Geo. W. Watts, Toronto; Robert Hobson, Hamilton; Senator William C. Edwards, Ottawa, and Geo. G. Mackenzie, B.Sc., Superintendent of Mines, Ottawa. Messrs. Cantley, Carnegie and Watts were members of the original Shell Committee.

N. T. R. TRANSCONA SHOPS TO MAKE MUNITIONS

IT is reported that the Government has leased the Transcona shops, near Winnipeg, of the N. T. R., to a powerful private company, organized for the manufacturing of shells and war munitions generally. These shops, which are part of the equipment of the National Transcontinental Railway, and which were erected and fitted with the most modern machinery procurable, are well adapted for the manufacture of shells, but have been practically idle since the war broke out.

The personnel of the company has not been definitely learned. It is known that the Mackenzie & Mann interests have been negotiating for some time for a lease of the shops for the purpose mentioned, but whether that company has secured the lease or not is not learned. A rumor to the effect that Sir Herbert Holt, of Montreal, and a group of other financial men have secured the lease is current.

The Government has had a splendid opportunity of contributing toward the shell supply of the allied armies at reasonable prices by the utilization of both the Transcona and Leonard shops, but both of these institutions have been left practically idle while companies have been formed all over the Dominion and new plants established for the manufacture by private individuals of shells at large profits.

It is understood that the men now employed in the Transcona shops have been notified that after a certain named date they were to look to the new company for their salaries, and not to the Government. Only a portion of the shops will be retained by the Government for the ordinary work of railway rolling stock repairs.

SHELL ORDERS FOR ALLIES

THE scope of the Canadian Shell Committee, or the Imperial Munitions Board as it is now called, may be enlarged before long to include the placing of orders for both the French and the Russian Governments.

Thus far the committee has had charge of the placing of munition orders in Canada for the Imperial authorities only. British orders have had the preference all along with Canadian manufacturers, for obvious reasons.

The shell making capacity in Canada, however, has now increased to a point that will probably permit of Canadians assisting in the manufacture of munitions for both the French and the Russian Governments on a fairly large scale, and in well-informed circles it is stated that proposals looking towards the extension of the Munitions Committee's activities are now actively under consideration.

If the proposals are carried out, an important feature will be the unification of the work. Instead of individual firms going after orders which they understand are under negotiation, the Munitions Committee will be able to act as a central bureau, bringing the Russian and French authorities into touch with the manufacturers. This will permit of business on a much larger scale than could be attempted if individual effort were depended upon, and the results should be satisfactory to both the Allied Governments and the Canadian manufacturers.

Major George Janin, city engineer of Montreal, who commanded a corps of engineers which he raised himself for war service, was drowned when the hospital ship Anglia sank after striking a mine. Major Janin was born in Paris, and saw service in the Franco-Prussian war. He was city engineer for twenty years.

Large Shells: Production Problems and Possibilities--IV.

By C. T. D.

In preparing to undertake the production of large shells up to 9.2 in. dia., manufacturers will encounter problems of a nature altogether different from those connected with 18 pdr. shells. Automatic machinery will not be so applicable to the larger sizes, and productive ability will centre largely on such points as sequence of operations, tooling methods, etc.

THE operations referred to in group C present no great difficulty. The principal dimensions and surfaces by which the work is to be held, driven, located or measured have already been established and these operations call for little remark further than indications as to chucking and driving methods.

Operation C 1 can be performed to advantage in any available drill press. A tubular chuck of generous dimensions is accurately located under the drill spindle. This chuck is made with one half hinged to open like a door to admit the shell from the side and avoid having to lift it up and lower it endwise. While the

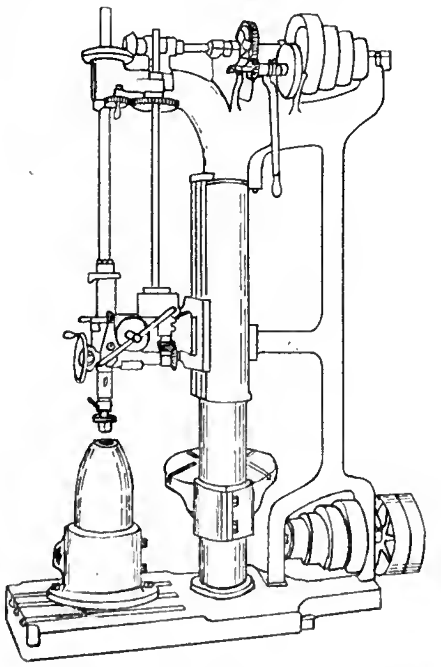

FIG. 9. TAPPING NOSE IN DRILL PRESS.

catch-bolt is being tightened, the shell should be shaken so as to ensure its being held perfectly vertical. This may be further insured by relieving the side walls of the chuck so that it grips the shell at the top and bottom of the parallel portion.

A service plug is now inserted in each end of the shell. These plugs should be accurately made to gauge size and hardened. In order to save time later, the nose plug may be made in the form of an eyebolt, or if desired, it may have a substantial boss, preferably of square shape, through which a shackle bolt may be passed.

The simplest form of driving plug for the base end would be provided with a square boss to engage with a driver in the face plate of the lathe. Turning the

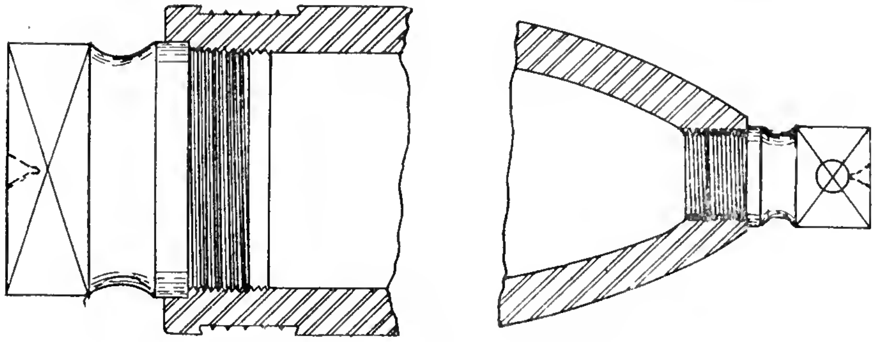

FIG. 10. SERVICE PLUGS FOR BASE AND NOSE.

shell to finished diameter, and forming the profile is accomplished with any of the numerous types of attachments already in use on small shells.

The base end of the shell having been previously faced, so as to bring the overall length of the shell within definite limits, this surface may now be used as a point from which to gauge the form of the shell, the gauge and method of applying it being shown in Fig. 11.

To avoid undue complications on the carriage, grooving and waving are most efficiently performed on a machine specially fitted up for this operation. Owing to the slight differences in centres and plugs, there may occur variations in the exact locations of successive shells necessitating the provision of means for adjusting the grooving and waving tools to suit. This is avoided by chucking the base of the shell, with the end positioning from a step in the jaws.

The shell is now ready to receive the driving band after the necessary chisel cuts have been put in the waves. The radial type of press with converging cylinders is best adapted for work on large shells. The nose plug which has been retained in place is now used for

OPERATION TABLE.

Operation Number	Description.
	Group A.
1	Grind off scale on point, forming small flat.
2	Place on expanding arbor which locates shell from inside, and positions it lengthwise from inside of nose.
3	Face-off nose of shell to necessary thickness.
4	Drill centre with drill in tail stock, remove drill and adjust dead centre.
5	Rough turn body, commencing at nose and traveling to point where open end of shell is cut on.
6	Cut off open end of shell to length measured from nose.
	Group B.
1	Drill hole in nose, leaving stock for final boring.
2	Chuck by nose with outer end in steady. Nose of shell in contact with gauge stop on chuck.
3	Bore parallel portion with roughing and finishing cutters.
4	Form interior of nose or arch.
5	Finish overall length and counterbore. Tap base.
	Group C.
1	Tap nose.
2	Insert threaded driving plug centre in base, and common threaded plug centre in nose.
3	Finish outside to size and shape.
4	Machine and undercut groove. Wave ribs.
	Group D.
1	Press on driving band.
2	Machine driving band.
	Group E.
1	Remove service plugs and assemble base plug and nose bushing.
2	Face off base and finish bushing.
3	Enamel interior and bake.

suspending the shell from suitable tackle. The service plugs may be removed now or left in place till after the band is machined. As a matter of safety both for the operator and the finished band it is preferable to remove the base plug now, replacing it with the proper article. This procedure offers the opportunity of facing off the plug in the machine which turns the band, and if the shell has been thoroughly cleaned out previously, the service plug in the nose will have prevented the entrance of any foreign matter, so that when it is removed, the shell may be varnished and baked without further delay.

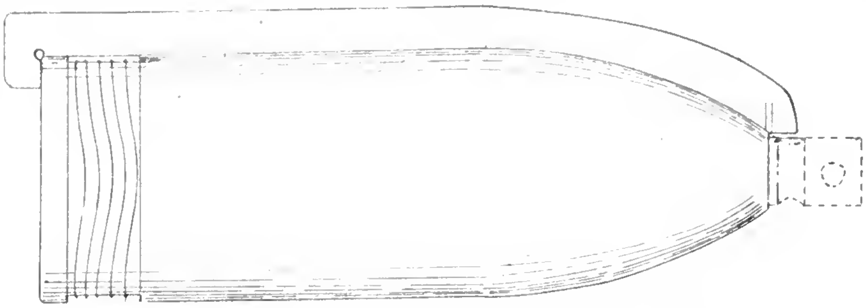

FIG. 11. GAUGE FOR OVERALL LENGTH AND PROFILE.

Single Purpose and Other Special Machines

As previously mentioned, the operations referred to above are arranged with a view to making immediate use of existing machines. The economies to be affected by the adoption of special purpose machines will not be overlooked by progressive manufacturers, and the foregoing methods will be adhered to just so long as they serve their purpose in other words when special machinery is obtainable, both machines and methods will be considerably rearranged so that as facilities for increased output become available, the older type machines will be relegated to such minor operations as they are best suited for.

Single purpose machines for boring, profiling, thread milling, and band turning are being rapidly placed on the market, and with reasonable delivery, manufacturers in this country should be able to proceed with work on the forgings as soon as they are received.

Through the courtesy of various tool building concerns, it is possible to illustrate and describe some of the more interesting machines which have been developed for handling the larger sizes of shells.

The Amalgamated Machinery Corporation of Chicago, have placed on the market a line of special ammunition machines, in two sizes, one for shells up to and including 4.5 in. and the other from 4.5 in. up to and including 12 in. These machines are all that are necessary for all roughing and finishing operations where the work revolves against a stationary tool. Strength has been especially regarded in their design and they are amply capable of performing any service required.

For the larger size shells, four machines have been designed, for turning, boring, drilling, and trimming.. These are all single purpose machines, and are naturally more effective than ordinary lathes, drills, etc., on repetition work.

Two of the larger size machines are illustrated herewith. The No. 21 turning machine, see Fig. 12, weighs approximately 18,000 lbs. The carriage has quick power return, with automatic stops for both directions. Power is received through a 16-in. x 12-in. pulley, and transmitted through a double back-geared drive to the spindle, the gear reduction being 16 to 1. A choice of any one of nine feeds is offered, from .026 in. to .200 in. per spindle revolution. The

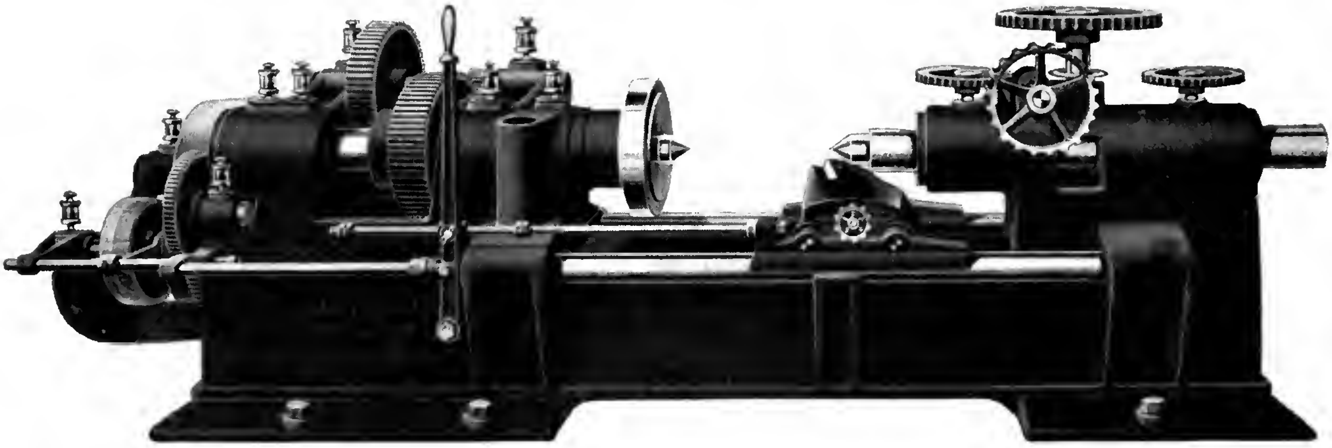

FIG. 12. SINGLE PURPOSE MACHINE FOR TURNING SHELLS FROM 4.5 IN. to 12 IN. DIA.

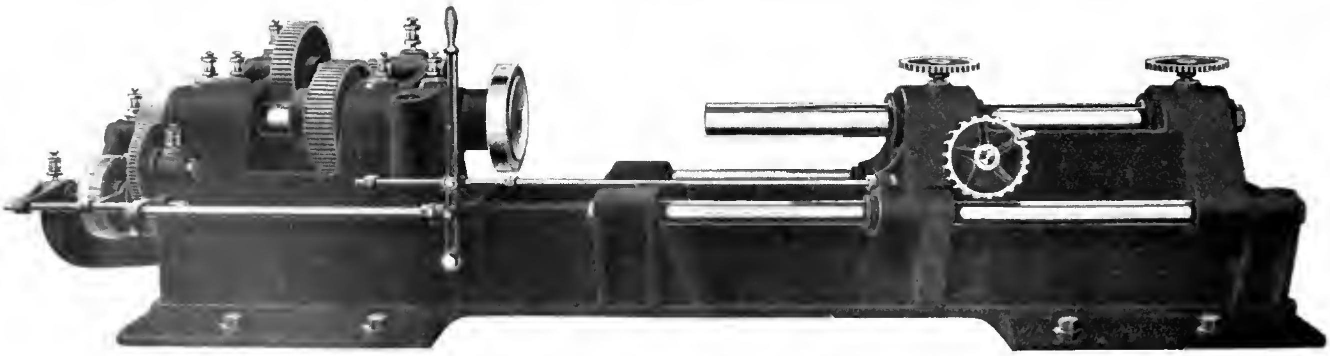

FIG. 13. DRILLING MACHINE FOR BORING LARGE SHELLS

regular feeds are .031 in. for machines on finishing, and .059 in. on machines doing roughing operations.

A feature of the carriage operation is the independent quick return which is directly driven by belt to friction pulley on the feed screw, and this travel is independent of the spindle and may occur while the spindle and work are at rest. Both feed and quick return are at all times under the control of the operator by means of a single hand lever conveniently placed, and adjustable automatic limit stops are provided for the carriage travel in both directions.

The tool holder will take a 1¼-in. square tool, which is seated in a pocket machined in the tool slide at a suitable angle and inclination, so that forging and grinding on the tool are reduced to a minimum. The spindle, which is 5 15-16 in. dia. of high-carbon steel accurately ground, is furnished with plain nose, attachment face-plate, No. 7 Morse taper centre, plain or with any specified fixture sleeve shrunk on, at purchaser's option. These machines are regularly furnished with former attachment, and one former made to purchaser's requirements.

The tailstock proper is cast integral with the frame and headstock, and is provided with ample clamping facilities to maintain it perfectly rigid. The actual swing over ways is 27½ in., over carriage 13 in., and floor space required is 4 ft. x 17 ft.

The No. 23 drilling machine, Fig. 13, made by the same firm, is similar in general features to the machine just described, the driving gear and headstock being identical. The tailstock is replaced by a carriage having an extreme length of bearing on the ways of 67 in., and a travel of 44 in. Longitudinal feed by hand is provided, which may be operated alone, or at the same time as the power feed, to accelerate or retard the latter, the length of travel being 44 in.

An option of any one of fifteen different power feeds is offered, from .006 in. to .200 in. per revolution of spindle, while an independent quick return by 4-in. belt drive is provided. Two widely separated supports for 5 15-16-in. bar or tool holder with powerful clamping devices are provided on the carriage, which is properly aligned with the spindle. Ample thrust bearings are provided on the spindle and feed screw. The general dimensions, capacity and weight of this machine are similar to No. 21, but the floor space required is 4 ft. x 21 ft., the increased length being due to the boring carriage. A detail in the design of these machines is the provision of a socket on the headstock to receive a crane mast for handling the shells.

OIL LEAKAGE FROM RING-LUBRICATED BEARINGS

THE leakage of oil from a ring-lubricated bearing may be due to several causes. Sometimes oil leaks through the horizontal keep joint of the bearing. The best remedy for this is to place a lead wire as packing in the joint. Bearings on large motors and generators often have a deep groove in the bottom half of the bearing, which groove, at both ends, communicates with the oil reservoir, and returns such oil as may have reached the joint by splashing out from the well through the motion of the lubricating rings.

Sometimes leakage will be observed along the shafting. It is important that there should be good clearance between the outer lip and the shaft, and if it is too close a fit it should be eased. If the oil still has a tendency to creep along the shaft, an oil-thrower can be made in halves and fitted on the shaft, or it may simply be a piece of steel wire bent round the shaft and clinched so that it will keep its position. Grooves in the bush will arrest the greater part of the oil, whilst the remainder is thrown off the collars. The keep may be fitted with an internal lip, which prevents oil splashing out through the joint.

Ring lubrication is very effective, as the oil is continuously lifted by the ring or the rings over the shaft, and finds its way into the oil-distributing groove, whence the film of oil between the shaft and the bearing is kept amply renewed. Care should be taken that the oil-carrying grooves are well rounded in the direction of rotation, to facilitate the entrance of the oil between the frictional surfaces.—T. C. Thomson.

Autogenous Welded Joints. — The strength of the joint produced by autogenous welding, it is pointed out in a paper on high temperature flames in metal working, has been a fruitful source of discussion in the application of the process, and many contentions have been advanced as to the necessity of welds of highest tensile strength. It was early found that 100 per cent. welds, or, in other words, those having a breaking strength equivalent to that of the metal itself, could be produced, but the sacrifice of elongation and reduction of area materially lessened the apparent value of such welds. Present practice is directed towards securing a weld of good tensile strength, as compared with the strength of the plate, with high ductility, since thereby the service conditions are better fulfilled. The growth in understanding of such requirements has resulted in the production of methods which, combined with proper apparatus, may uniformly produce these results.

THE SUPER-GAUGE

NOT the least of the innumerable engineering problems raised by the war has been the production of a sufficient number of precision gauges to enable munitions to be built to the degree of accuracy demanded by modern warfare and its weapons. To land a shell within a few yards of the intended spot when firing from a concealed battery miles to the rear leaves no room for inaccuracy. The whole of the equipment has to be of the very finest design and construction, and the complexity of those methods of warfare which permit gunners to destroy defences which they cannot even see, introduces innumerable opportunities for error, and, therefore, makes yet more remarkable the extraordinary accuracy actually achieved.

Accuracy, however, is not and can not be easily secured. To take only a single link in the chain of things and events connecting the reconnoitring aeroplane with the destruction of the enemy's works by indirect gunfire, we have in the shell itself a remarkable engineering production consisting in its simplest type of a number of component parts, yet so perfect in its components and in its whole that hundreds of thousands of rounds can be expended with certainty of obtaining the desired results, however the shells be distributed between a thousand guns. Were it not so, warfare as we know it would be impossible, and it is not pleasant to contemplate the possible results of any inaccuracy in production. At the best it could only result in expenditure of ammunition to no effect, at the worst it might cause destruction of our own troops, incapacitation of our guns (by jambing), and even the loss of a minor or major action.

Such possibilities are not pleasant to contemplate, and to the uninitiated it might seem that the worst could so easily happen. In producing shells by the million, at a rate never before attempted, can we be sure that that tiny fraction of error which would spell tragedy or disaster shall never creep in? We trust and believe that we can. On the one hand, we have our best engineering firms making (inter alia) gauges for shop use, and on the other hand, we have the National Physical Laboratory passing under the seal of its authority a vast family of "super-gauges" for use by inspectors of munitions. Surely nothing defective could escape the close-drawn meshes of this double screen. The responsibility resting on our enginers is indeed immense. It sobers one to think of it, but every human precaution is being taken, and if there are those who have been a little disheartened by the severity of requirements, let them remember that these requirements are literally essential. Engineering Review.

Lathe Centres, Their Design and Application Features

By H. G. Fogarty

The necessity of maintaining lathe centres in a state of suitable accuracy is not always appreciated to an extent which their importance justifies. Opportunities for the application of special types of centres are more frequent than is generally supposed, and while a small expenditure of time and material is necessary to make them, the increased accuracy of the work produced and other obvious advantages more than repay any small initial cost.

THE importance of keeping lathe centres in perfect condition is a fact which most mechanics realize and few put into actual practice. Accuracy in lathe work chiefly depends upon the accuracy of centres and upon the

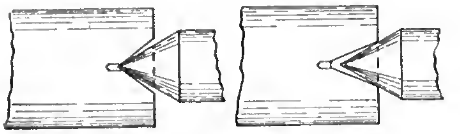

FIG. 1.

way in which the piece to be machined is centred.

Springing Shafts in Lathe

One of the most common practices which tends towards putting the centres in such a condition that they become practically useless for producing accurate work, is the use of the lathe for springing on straightening shafts. This practice is more or less common in repair shops but also exists in many seemingly well regulated manufacturing plants. The constant pounding and jarring which the lathe and lathe centres, chiefly the lathe, have to withstand under such treatment, and the damage from the same must indeed be evident to every mechanic. A lathe which is used as a straightening machine, can never be depended upon to turn out an accurate piece of work, for the chances are that the centres will be considerably out of alignment.

FIG. 2.

It must be admitted, however, that this manner of straightening shafts gives excellent results—as far as the shaft itself is concerned—but why use a good lathe for accomplishing this end? If the shaft is badly bent or kinked a straightening press, if one is available should be first used and the shaft then tried between centres. If it still requires straightening it should be put in an old lathe—which most shops boast of —and the necessary work done.

Heavy Cuts and Insufficient Lubrication of Centres

Another practice which proves costly to the centres, especially the dead centre, is allowing the shaft to run "dry," thus causing the centre to become cut and scored. The piece to be machined is generally put between centres, the dead centre having been first lubricated and brought up to bear with the desired pressure against the shaft. The lathe is now probably run at a high speed and a comparatively heavy cut taken, and before long it begins to "squeal." The cause of this is evident. The shaft becomes hot under the heavy cut and high speed and expands thus binding against the centres. The lathe should never be run while the centres are squealing. The tailstock should immediately be released and the centre again lubricated with either oil or red lead the latter giving excellent results.

Poor Centreing

Lathe centres are frequently put in a poor condition by the lack of common

FIG. 3.

sense when the work is being centred. The centre must be drilled to a sufficient depth to clear the point of the lathe centre, and should be countersunk or reamed to the exact angle. The standard angle for lathe centres is 60°. This insures a perfect bearing on all points of the centre. The poor bearing surface which is obtained when the centres are reamed either above or below the standard degree may be seen by referring to the accompanying sketch, Fig. 1.

Different Styles of Lathe Centres

It might be well to admit at first that the styles of lathe centres differ only in so much as the means of removing them from the spindle is concerned. Both the centre angle, which as was previously mentioned is 60°, and the spindle taper are standard. The taper used by the majority of lathe builders for their centres is the Morse standard. Among other standards, however, are the Brown and Sharp, the Reed, and the "Jarno" tapers; the taper ranges in these from about 0.6 inches to 0.625 inches per foot.

Removing the Centres

In order to remove the centres from the spindle some suitable means must be

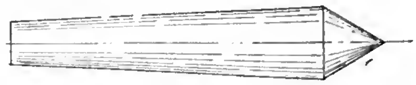

FIG. 4.

provided. As far as the dead centre is concerned it is usually removed by running the tailstock screw back to the limit thus forcing the centre out by means of the screw. In the headstock spindle, however, some other means must be employed. The old style of centre which had no means of being removed except by tapping it with a hammer or wrench until it became loose, has practically disappeared. This was a slow and expensive method at best, for the constant hammering on the centre had the tendency to gradually enlarge the hole in the spindle taper and put the centres out of alignment.

This old style of centre was followed by one which had a square or flat head, as shown in Fig. 2. This style is still used in many shops and it answers its purpose fairly well. To remove one of this style from the spindle, a wrench is placed on the square and by hitting the handle of the wrench a sharp blow, the centre becomes loosened and can be easily removed.

Still another style of centre is that shown in Fig. 3. This style is also used quite extensively, more especially on the older type of lathes. It is made as shown in the illustration, having the end turned down for a short distance back and threaded, the threads being about 16 or 18 per inch. A nut is fitted to this thread. To remove the centre all that is necessary is to screw the nut up against the spindle. This acts similarly to a small

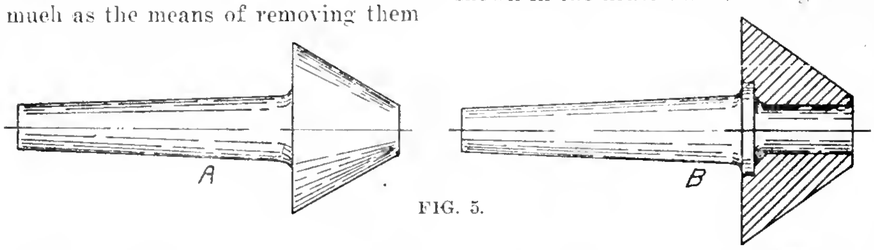

FIG. 5.

jack-screw, the tendency being to pull the centre out.

With the advent of the more modern lathes having a hollow spindle came the centre which is used now, most extensively. This is a plain centre as shown in Fig. 4, and to remove it all that is necessary is to insert a light bar into the back of the spindle and hit the centre a slight blow.

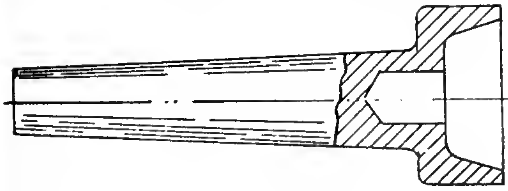

FIG. 6.

Special Centres

The centres which we have just referred to are all standard and are used only for straight or taper turning. Besides these there are several special centres in use but only a few of the more important will be mentioned here.

Pipe Centres

The pipe centre is one of the most common of these. It is often necessary on special jobs to turn or cut wrought iron pipe and if a plug has not been inserted in one end of the pipe a cone centre is used. Two other important styles of pipe centres are shown in Fig. 5. The one shown at A is turned from the solid; the angle of the bevel being about 60° for the smaller size of pipe, but for pipe of a large diameter a bevel angle ranging from 80° to 90° is advisable. As this style of centre is solid, the rough pipe end revolving on it soon cuts and scours it. The centre shown at B has proved itself most efficient for this particular line of work. The shank is made of steel and is turned down on the end to a suitable distance back leaving a sufficient shoulder or collar for the cone to bear against. The cone is usually made of cast iron and is bored to the size of the end of the shank, being a nice running fit. It might be stated that a fillet left in the shoulder of the flank would be more advisable than a sharp corner as it would insure a certain degree of strength to this part of the centre. When in use the cone revolves on the spindle with the pipe thus eliminating the cuts and scores which are common to the solid style of centre.

Special Centres for Drilling

The lathe is often used as a drilling machine, the drill chuck and drill being held in the chuck of the machine. In such a case a drill pad or centre as shown in Fig. 6 is used for holding the work. This centre needs no explanation, the hole being bored to any suitable size to take the work in hand.

Another style of drill centre is illustrated in Fig. 7. This centre is used chiefly for drilling holes through the cross section of a shaft or bar. To insure that the hole to be drilled will be in the direct centre of the piece considerable care must be taken in laying out the V so that its centre line will be exactly in line with the centre line of the shank.

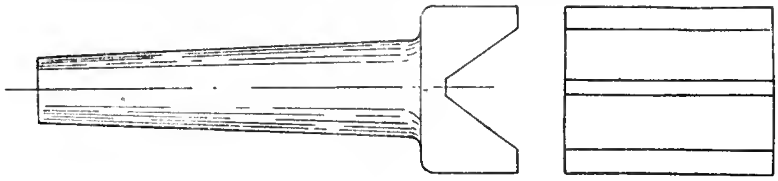

FIG. 7.

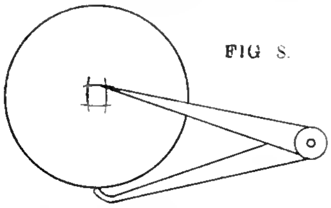

FIG 8.

Methods of Centreing

Probably the most common method employed in centreing shafts is by the use of calipers or more preferably the "haemaphrodites," which are made in the combined form of a caliper and divider. In using these the end of the shaft is first chalked so as to show the clear markings, and the calipers are set to a distance slightly greater than the distance to the centre of the shaft. Scratch marks are made from four points on the circumference, the appearance of the markings being similar to those shown in Fig. 8. The centre is easily located between these marks by means of a centre or prick punch. Centreing by means of a V block and surface gauge gives results similar to the methods just mentioned, but it is a practice that is not used in a great many instances. The V block is made as shown in the illustration Fig. 9, the base being planed to give a true bearing surface and the two Vs are machined in alignment with one another. The surface gauge and block with the shaft in place as shown, are placed on some level surface for instance the table of a planer and the end of the shaft is scratched as shown. The centre is then located by the same means as previously described.

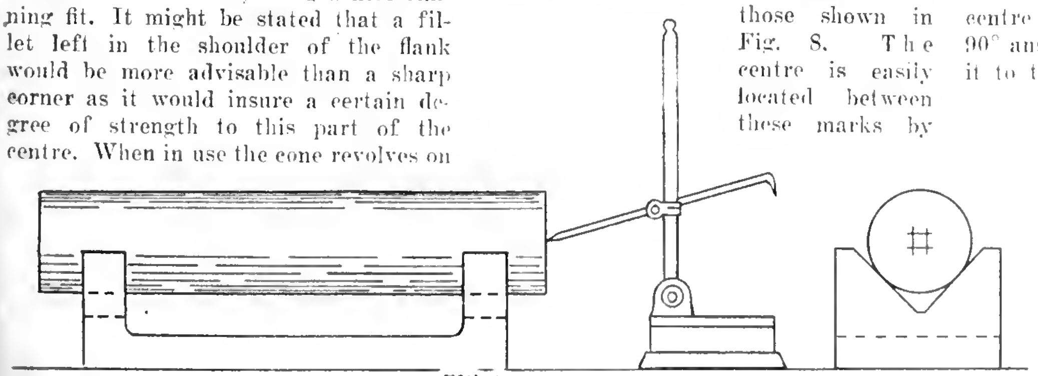

FIG 9.

Self-Centreing or Bell Punch

An excellent method of centreing is by means of the punch illustrated in Fig. 10. The cone is made of steel and is bored out, as shown, to a suitable bevel, preferably 60° to 70°. A hole is drilled through the centre of the bell casing, in which the centre punch slides. In using this punch all that is necessary is to place the bell or mouth over the end of the shaft and hit the centre punch a blow with a hammer. This gives an accurate centre providing care has been previously taken in holding the punch square with the work. If the punch was placed over the shaft in a tilted position as shown in sketch B, Fig. 10, the accuracy of the centre then marked could not be depended upon.

Centre Square

By the use of the centre square, which is included in every combination set, a method of centering either rounds or squares may be employed which is compelled to insure accuracy. No hesitation is necessary in saying that centreing by this method is the best and most economical in every respect. The body of the centre square as shown in Fig. 11, is a 90° angle and a slot is machined through it to take the sliding scale. The scale is made with a narrow slot cut along its entire length, which engages with a lug in the body of the square. By this means

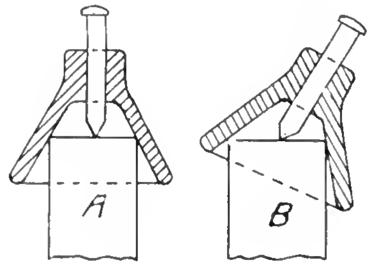

FIG. 10.

the scale can be adjusted to any length and is held in any desired position by tightening the knurl screw, which causes the lug to bind against the slot in the scale. All that is necessary in centreing with this tool is to hold the square over the end of the shaft as shown and describe a line. Move the square farther around on the circumference and discribe another line. The point where these two lines intersect being the exact centre of the shaft.

Lathe Centreing

There are several methods of centreing work in the lathe, the most common practice being by means of the square centre shown in Fig. 12. The square centre A, has a taper turned to fit the spindle of the tailstock. A hole is drilled through its entire length, one end of which is squared in order to take the tool which is made from ⅝ in. or ¾ in. square tool steel. This tool is ground to a 60° angle, and considerable clearance is given to the bottom side. This clearance enables the tool to enter the required distance. If the tool is ground otherwise, that is with very little clearance it would only be possible to mark the end of the shaft. This may be readily seen by referring to sketch D, Fig. 12.

In centreing by this method the shaft is first rough centred by means of a heavy centre punch. It is then put in the lathe between the centres, the square centre just described taking the place of the dead centre.

The tool illustrated at C, Fig. 12, is clamped in the tool post, the lathe carriage having been run back so that the fork will come opposite the end of the shaft to be centred. The shaft is then driven by means of the face plate and dog; the square centre is gradually fed in, while at the same time the tool post is fed across, the forked tool forcing against the end of the shaft till it runs perfectly true. The centre thus made is next drilled to the depth which will be sufficient to clear the point of the centre. The most suitable drill to use for this is the well known combination drill, which is made in several different sizes, the angle of the reamer being the required degree for the centre.

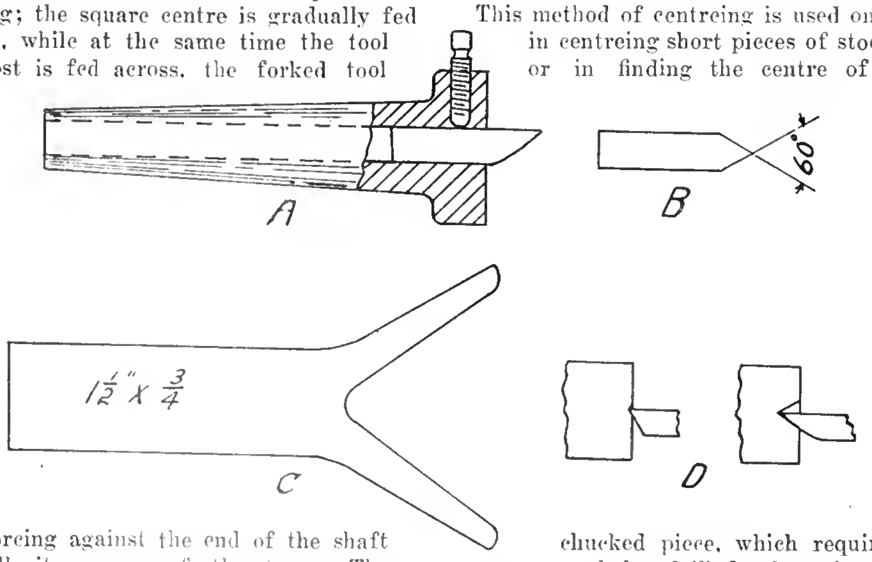

FIG. 12.

Chuck and Steady Rest

This method of centreing bars is also extensively used and is found to give entire satisfaction, especially when several pieces of the same size are to be centred. One end of the bar is chucked true, while the other end is held in the steady rest, the jaws of which are set centrally for the size of the bar. A combination drill is held in the tailstock spindle and this is fed into the stock, thus centreing it. In using this method a universal chuck is desirable, but either a three or four-jawed independent chuck may be used without the necessity of truing up each separate piece. By loosening one jaw in a three-jaw chuck, or two jaws in a four-jawed chuck, the work will be released and another one can be chucked in exactly the same position.

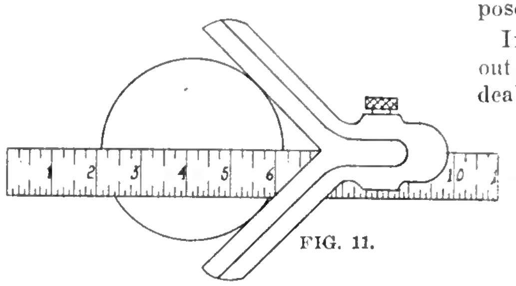

FIG. 11.

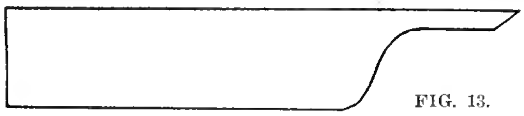
Spot Centreing

This method of centreing is used only in centreing short pieces of stock, or in finding the centre of a chucked piece, which requires a hole drilled through its centre. The tool for this purpose is illustrated in Fig. 13, care being taken to have suitable clearance back from the point and cutting edges of the tool. This tool is clamped in the tool post, being so adjusted that it comes in the exact centre line of the work, and in operation the lathe carriage is moved forward till the tool "spots" the centre. A slight pressure will force the point and cutting edges into the work, thus enabling a centre of sufficient depth for the purpose required to be made.

If the foregoing remarks are followed out there is no doubt but that a great deal of the trouble often encountered in securing perfect centreing will be eliminated, and as a result better and more accurate work will be turned out.



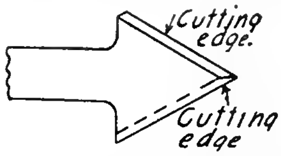


FIG. 13.

CONCERNING EXPLOSIVES

IN a paper by Professor Percy F. Frankland, read before the Birmingham Section of Chemical Industry, the author said:—"The disruptive properties of gun-cotton are greatly moderated by gelatinizing by means of solvents—acetone, acetic ester, alcohol, ether, etc.—and by mixing with nitro-glycerine ballistic materials like cordite and other smokeless powders are obtained.

There is still another class of explosives which combine great safety in handling with enormous disruptive effect—picric acid, discovered by Woulfe, of London, in 1771, but first used by the French under the name of 'Melinite' for filling shells in 1881, and later by the English under the name of 'Lyddite.' More recently this has been replaced by trinitrotoluene, first proposed by Haeussermann in 1891 for filling shells, and used by our service under the mark 'T.N.T.' It is even less sensitive to shock than picric acid. 'Ammonal,' used by the Austrians for shell-filling, is a mixture of 'T.N.T.' with ammonium nitrate, charcoal and aluminum powder. It is both very safe and very powerful. 'T.N.T.' is much used for demolishing bridges. It is so insensitive to shock that it is not exploded on being struck by a rifle bullet, and when in a shell it withstands the impact of the latter piercing an armour-plate.

"Tetra-nitro-aniline, obtained by Flurscheim, enjoys the unique position among explosives of having been discovered in Great Britain. It is said to be as safe as, and even more powerful than, trinitrotoluene."

The Algoma Steel Corporation, Sault Ste. Marie, Ont., is selling a quantity of electrical equipment formerly used as an auxiliary lighting plant.

Sheet Metal Elbows, Their Development and Laying Off-V.

By J. W. Ross

In order to thoroughly understand the principles involved in the development of cylindrical and other forms, such as are met in sheet metal work, a considerable knowledge of geometry is desirable. Through the medium of these articles, the author places practical examples at the disposal of our readers, and the knowledge to be gained by a close and persistent study of the principles and methods employed will well repay the time spent.

ELBOW AND OVAL-SHAPED CROSS-SECTION

FIG 24 shows elevation and cross-section plan views of a five-piece 90-degree elbow, the cross-section plan being shaped oval fashion, with two flat sides.

The elevation and mitre lines are drawn as in preceding problems. The

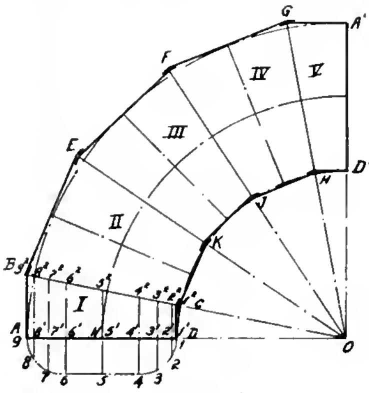

FIG. 24.

neutral diameter AD is equal to 24 inches and the radius OD to 27 inches. Divide AD into 4 equal parts as $6^15^14^1$. With 6^1 as centre and 6^1A as radius strike the neutral quadrant A6. Also with 4^1D as radius and 4^1 as centre draw the quadrant D^4. Draw the line 6 5 4 parallel to AD and tangent to the two quadrants. The half cross-section plan is shown by A654D. Divide the quadrants A6 and D4 each into the same number of equal parts, projecting these points—through and at right angles to AD—to the mitre line BC. Number all points in consecutive order and in relation to each intersecting line.

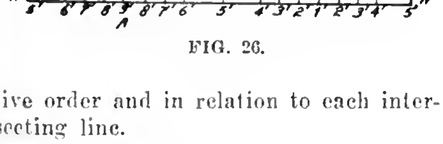

FIG. 26.

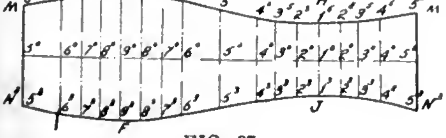

FIG. 27.

Twice the length of the flat side 6 5 4 added to the circumference of the circle obtained from its diameter by the combined radii of the two quadrants as $A6^1$ and $D4^1$ will equal the stretchout of the plate, which equals $(2\times12)+(12\times3.14)$ equals 24+37 11-16, equals 61 11-16 in. Measure 61 11-16 inches along the line $N5^1N$, Fig. 26. Bisect at 5^1. Measure off 5^16^1 and 5^14^1, Fig. 26 equal to 5 6 and 5 4, Fig. 24, which equals 6 inches each. Measure of 6^16^1 and 4^14^1, Fig. 26, each equal to the quarter circles 9 6 and 1 4, which is 9 27-64 inches. The end distances, 5^16^1 and 4^15^1, are then each equal to 6 inches. Divide 6^16^1 and 4^14^1, Fig. 26, each into twice the number of parts as in each quadrant 9 6 and 4 1, Fig. 24. Through these points erect perpendiculars, and number accordingly. Transfer the distances as 9^19^2, 8^18^2, etc., Fig. 24, over to their corresponding numbers on Fig. 26.

Fig. 26 shows the full pattern for courses I and V and the half pattern for course III, laps, etc., to be drawn in.

Courses II and IV are developed similarly to course W, Fig. 18, using the neutral diameter and cross-section similar to course I, Fig. 24. The stretchout for courses II and IV will be equal to 61 11-16 + 7 times the plate thickness for a slack fit. The pattern is shown in Fig. 27.

Elbow with Square Section

Fig. 28 shows the elevation and square section plan view of a 3-course 90-degree elbow. The neutral diameter AD equals 24 inches and DO 27 inches. The elevation and mitre lines are in the usual manner. $A^1D^1D^2A^2$ shows the plan view. The stretchout is equal to the sum of all the sides of the neutral section. Measure off D^1D^1. Fig. 29, equal to 4×24 inches, which equals 96 inches. Divide this into 4 equal spaces representing the 4 sides of the square. Erect perpendiculars through these points as shown by $D^1D^2A^2A^1D^1$, Fig. 29. Make D^1C, D^2C, Fig. 29, each equal to the length DC, Fig. 28. Also measure off A^1B, A^1B, Fig. 29, each equal to AB, Fig. 28. Connect these points with straight lines as shown in Fig. 29.

The templet without laps for courses I and III is shown in Fig. 29. Fig. 30 shows the pattern for course II and is self explanatory if the preceding problems have been thoroughly understood.

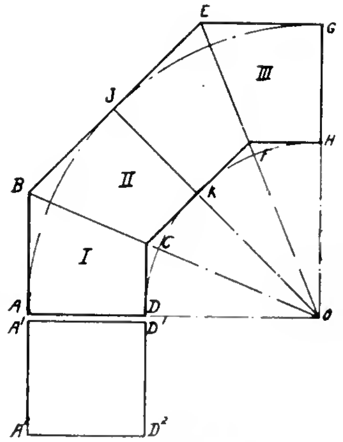

FIG. 28.

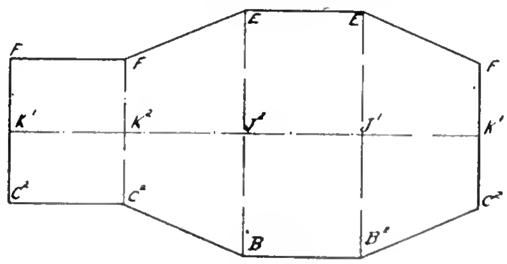

FIG. 30.

HARDENING HIGH-SPEED SCREW MACHINE TOOLS

By R. A. Mulholland*

NOW that the price of high-speed steel is soaring, it behooves the machine shops of the country to give serious thought to the conservation of their present supply. Much good steel is wasted every day through poor practice in heat treatment. A tool improperly hardened naturally has to be ground oftener than a properly hardened one, and the result is a serious loss in manufacturing time and a waste of perfectly good high-speed steel.

All the up-to-date methods may be practised in the hardening, and yet the tool may prove unsatisfactory when run at the speed and feed that high-speed

*Consulting Metallurgist, Indianapolis, Ind.

steel will stand when properly treated. Some of the most serious troubles have been experienced in the hardening of screw machine tools, such as special shaped cutting-off tools, box-turning tools and facing tools—in fact, any tool that is ground from the annealed bars as they are received from the mill, and have one of the cutting edges on one of the sides of the annealed bar. Especially is this true of the box-turning tool where generally little or nothing is ground from the face of the tool stock. Most of these tools are made from ½ x 1 in. stock, and require no forging before they are ground on the emery wheel.

The practice of making stock-removing screw machine tools should not differ in any essential from the making of taps and the more delicate tools that are made in the tool room. What competent tool-maker would think of making an expensive tool from a piece of stock that was just large enough to "clean up?" Did you ever stop to consider why the experienced tool-maker always turns off at least 5 per cent. of the diameter before attempting to make a tool that must have an enduring cutting edge? The theory is the same for large and small tools. The reason is that the annealed bars as received from the mill have a thin shell of decarbonized scale, so to speak, on the outside. This decarbonized area must be removed before a good cutting edge can be secured that will harden satisfactorily.

A simple method for doing this is to grind the tool to its approximate shape, and then put it in the milling machine and remove about 5 per cent. of the thickness of the stock from the surface that is to be the cutting edge. If this is done, when the tool is properly hardened it will have its maximum cutting capacity and will run longer on fewer grindings than will the tool made from the rough stock without first removing the decarbonized area. The practice of disregarding the decarbonized area in all forms of tool steel has always been and always will be a great source of loss both in the efficiency of the tool and the cause of excessive tool steel bills.

The actual hardening of high-speed steel is a comparatively simple matter, and if the tool is properly prepared for hardening there is little doubt that the result will be better than the average shop is now obtaining from the careless way that high-speed screw machine tools are made in a large number of plants.—Iron Age.

MANGANESE BRONZE

LARGE quantities of non-ferrous scrap must accumulate from time to time, and the problem of its economic disposal is of interest. The methods used at the Washington Navy Yard were recently described in a paper before the American Society of Naval Engineers by Lieut. J. B. Rhodes, U. S. Navy, dealing particularly with manganese bronze. The following materials were available, with the compositions approximately as shown:

1.—Naval brass: Copper, 62 per cent.; zinc, 37 per cent.; tin, 1 per cent.

2. Cartridge-case metal: Copper, 68 per cent.; zinc, 31.6 per cent.; nickel, 0.4 per cent.

3.—Manganese bronze: Copper, 59 per cent.; zinc, 41 per cent.

4.—Commercial brass can be used in small quantities, but should be avoided, as the lead content is too high.

The results of experiments during about six months have shown that it is practicable to make high-grade ingots in an oil-fired "Rockwell" furnace of about two tons capacity. This has been accomplished in spite of the well-known prejudice against open-flame furnaces in the manufacture of non-ferrous alloys. Oxidation has been reduced to a very small amount by using wood scraps from pattern shop, and salt. The bath is protected by the molten salt, and the wood ensures a reducing rather than an oxidizing atmosphere in the furnace.

In undertaking the manufacture of manganese bronze a special hardener is first made, and is regarded as the secret of the whole process. A satisfactory mix consists of 100 lb. copper, 25 lb. mild steel, 25 lb. of 80 per cent. ferro-manganese, made by melting the steel and alloy together, and then adding the copper as quickly as the melt will take it.

In using the scrap it is necessary to know the approximate analysis. The desired composition is:

	Per cent.
Copper	57.0
Zinc	40.0
Iron	1.0
Manganese	0.75
Aluminum	0.75
Tin	0.50

The usual losses in zinc, manganese, aluminum, and tin are allowed for, and a heat melted and cast. After analysis, the final adjustments are calculated and allowed for (particularly zinc, which must be 41 per cent. in the finished casting) when re-melting for use in the finished casting.

In melting in the oil furnace, the most difficult scrap to melt should be charged first, although all but finals may be charged at once. As soon as melted, the hardener should be added. In about half an hour, charge the remaining scrap (if charge is not made all at the same time) and continue the melt. After the heat is well up, add zinc, then tin (if necessary), and finally aluminum; stir well and tap. Small ladles are used for pouring the ingots. Ingots are numbered to show the heat, and turned into the store awaiting analysis. The cost of the method is high, on account of the labor in pouring and marking ingots, but, counting in furnace loss, labor, fuel, and upkeep of furnace it is less than 2 cents per lb., so that scrap worth 7½ cents per lb. can be converted into manganese bronze to cost not over 10 cents per lb.

One of the heats gave 82,000 lb. tensile strength, and 28 per cent. elongation. Quite frequently 75,000 lb. tensile strength and 20 per cent. elongation are obtained in sand castings. If high pouring temperatures are avoided and the metal is poured when it ceases to give off zinc fumes in large volume, excellent values will be obtained so long as the zinc content is kept at 41 per cent.

PLATING ALUMINUM WITH NICKEL

AN apparently successful method of plating aluminum with nickel is described in a recent number of the Bulletin de la Societe d'Encouragement pour l'Industrie Nationale, by J. Canac and E. Tassilly. The process permits the direct deposition of nickel on aluminum in an adherent form. The metal is cleaned by passing it through a bath of boiling potash and then scrubbed with milk of lime. After soaking in a bath of 0.2 per cent. potassium cyanide for several minutes, it is submitted to the action of an iron-hydrochloric acid bath. 500 parts HCl, 500 part H_2O and one part iron, until the metal takes on a certain appearance described as metallic "watering." It is washed with water after each of these operations.

The formula found satisfactory for nickel plating is:—Water, 1,000 cu.c.; nickel chloride, 50 grams; boric acid, 20 grams. The current is 1 amp. at 2½ volts. The plated metal is said to have a pleasing soft gray appearance, easily taking a metallic luster when polished with a wire brush, the plating being remarkably adherent. It is claimed to endure hammering and to bend in sheet form without cracking. The metal, as cleaned in the iron-acid bath, shows under the microscope a surface full of minute cavities in which the nickel deposits and adheres.

Quarter Turn Drive.—We are advised by F. Reddaway & Co., Montreal, that for the "Quarter Turn Drive," described and illustrated on page 366, October 14 issue of Canadian Machinery, a "Camel Hair" belt is employed. They further state that an 8-inch belt of same brand takes care of the crossed drive of a heavy planer in the same plant.

PROGRESS IN NEW EQUIPMENT

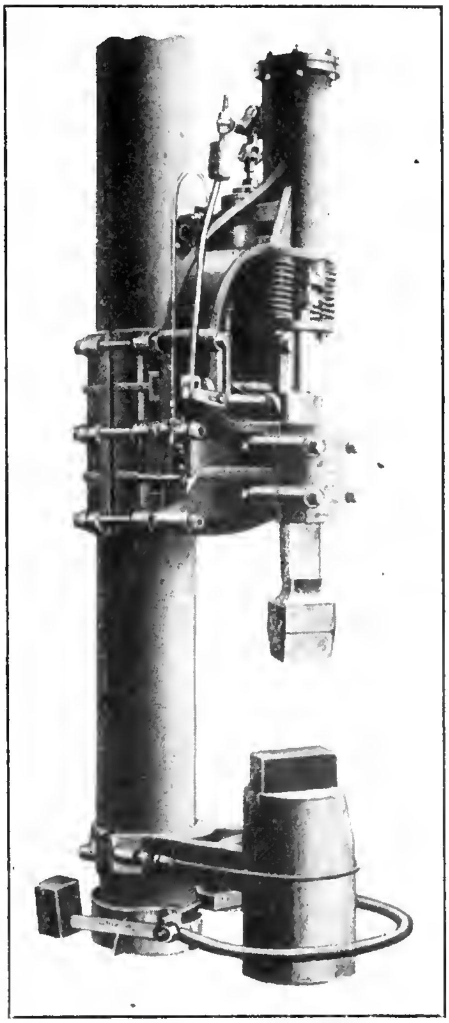
A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

IMPROVED TYPE POST HAMMER

THE Q.M.S. Co. have placed upon the market an improved type post hammer, as illustrated in the accompanying photograph. The extremely high price of tool steel makes it a valuable adjunct to any machine shop equipment. Short pieces of tool steel, which were formerly scrapped, can be drawn down and used for small lathe tools and in tool holders.

This hammer is particularly adapted for all classes of light forging and can be easily handled by a blacksmith, doing away with the necessity of a helper. The machine can be operated by steam or compressed air. A patented valve movement insures perfect control. If treadle is brought down to the limit, the ram will give a hard, full blow, the same as a drop hammer; or the treadle can be pressed down part way, when the ram will give repeated hard or light blows, as may be required. The change from one kind of blow to another is made instantly and smoothly.

The Vulcan Engineering Sales Co., Chicago, are distributors of this product.



IMPROVED TYPE POST HAMMER.

RAIL ENDING MACHINE

THE accompanying illustrations show a recent design of rail-ending machine for operating on the high carbon, high manganese, open-hearth rails, as made to-day.

The general outline of the machine, which is produced by the Newton Machine Tool Works, Inc., Philadelphia, Pa., closely follows preceding designs, with improvements in details of construction to provide for the high resistance encountered on the material referred to.

The motor is mounted on the top of the machine and drives through a ten-inch wide belt through phosphor bronze worm wheel and hardened steel worm of steep lead, the worm wheel being double-keyed to the spindle. The spindle is one-half the diameter of the cutter head; thus giving a sense of proportion which would not be obtained by quoting figures.

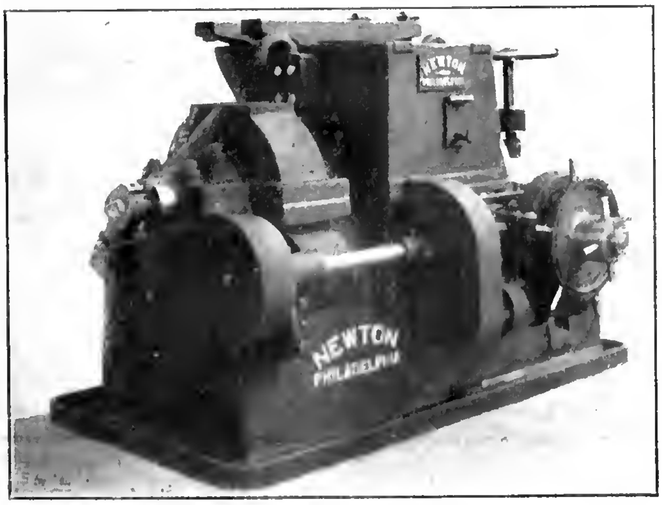
Bearings are capped and bronze bushed, so that compensation for wear is provided.

Feed is by stationary screw and revolving nut, thrust-bearing taken by enclosed ball bearings eight inches in diameter.

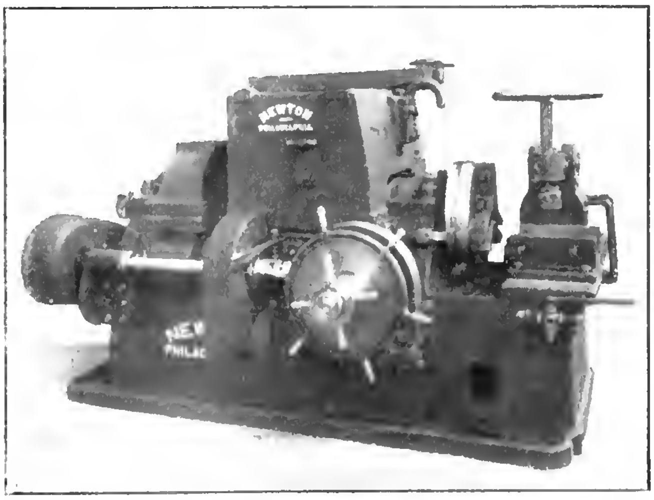
The spindle has a movement of $2\frac{3}{4}$ in. forward movement, having hand adjustment and four changes of feed amounting to 1/64-1/32-3/64-1/16 of an inch per revolution, the revolutions of the cutter head being from five to fifteen per minute. In addition, the spindle has adjustable automatic stop, with safety limits, so that spindle cannot jam at either end, and is also furnished with power quick return motion. All gears are fully enclosed and principal driving and feed gears run in oil.

The base is surrounded by the pan, and a circulating pump and distribution system for cooling the tools is provided. This includes cored openings in the base, which provides for the ready removal of chips. Lifting hooks are fitted so that the machine can be readily transported from one position to another to take care of the different lengths of rails encountered in the mill.

Cutter head is of the three-tool type, and can be used either with solid cutters or with tool-holders. Rails are clamped in a chuck, fitted with hardened serrated plates, the mouth of chuck be-



NEW DESIGN RAIL-ENDING MACHINE.



NEW DESIGN RAIL-ENDING MACHINE.

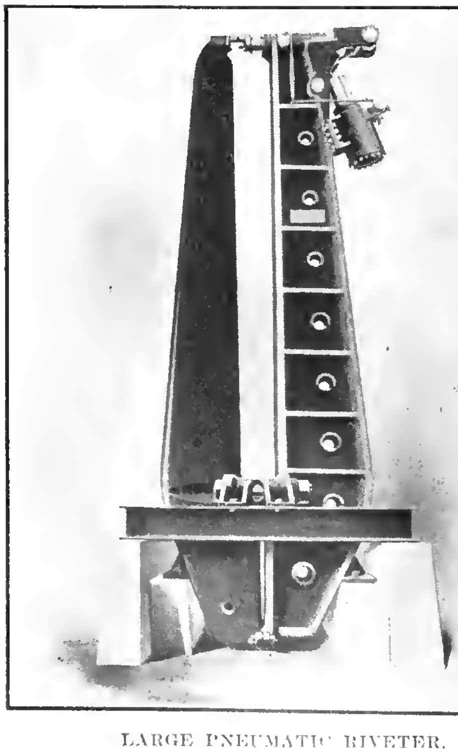
ing bevelled in all directions to provide for the ready entrance of rail. The clamp is of a patented clearance air-operated type, providing a clamping pressure of 32 tons, operation being by valve shown in the foreground of photograph. Adjusting screw on the air clamp is provided with hand wheel to take care of the various sections of rail placed in the machine.

These machines work in conjunction with machines for drilling splice bar holes, and in developing this machine the aim has been to produce a machine with a capacity on tee head rails in excess of that of the drilling machine.

LARGE PNEUMATIC RIVETER

THERE have recently been built by the Hanna Engineering Works, Chicago, what are believed to be two of the largest pneumatic riveters in existence. Each machine has a reach of 21 ft., and is capable of exerting a pressure of 100 tons on the rivet die at 100 pounds air pressure. An idea as to its size can be obtained when the weight of 40 tons is considered.

In this riveter, have been combined in a simple form, toggles, levers and guide links to give the large opening of the toggle joint movement with its gradually increasing pressure until the desired pressure is reached, and a simple lever movement throughout a considerable space under approximately maximum pressure. This space is sufficient so that there need be no uncertainty about the pressure applied on rivet; and the machine once adjusted for a certain length of rivet and thickness of plate, will require no further adjustment for ordinary variations in length of rivets, size of holes, or thickness of plates, thus producing hydraulic results with a pneumatic riveter.



LARGE PNEUMATIC RIVETER.

These heavy duty riveters are furnished with cylinders having 22 inches of piston stroke with a relative travel of 5¾ in. of the rivet die. As in the smaller machines, the toggle action takes place during the first half of piston travel, that is 11 inches, which represents approximately the first 4¾ in. of die travel. At this point the mechanism automatically changes into a simple lever action, without a critical point, thus producing the rated tonnage of the machine at the rivet die, and practically uniform for the last inch of the die travel.

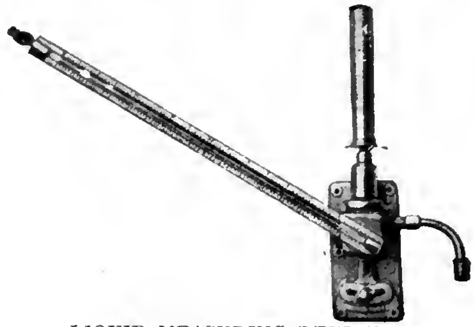
By the use of an inexpensive pressure regulating valve in the air supply line to riveter, the pressure of air at the cylinder can be quickly changed to vary the pressure on the rivet dies to produce any tonnage the operator may deem advisable for any size of rivet he may wish to drive.

This is a large machine and marks a new era in the riveting world. The Vulcan Engineering Sales Co., Chicago, are placing these riveters on the market.

LIQUID MEASURING DEVICE

A NEW measuring instrument for indicating the quantity of liquid contained in tanks and similar storage receptacles is now being placed on the market. The device operates on what might be termed a hydro-pneumatic principle, and its successful adaptation to industrial requirements will enable the abandonment of floats, gauge glasses, and similar mechanical devices which are not always satisfactory from the point of accuracy, reliability, ease of observation, etc.

Stancliffe's patent liquid measuring device operates through the medium of a metal tube, one end of which is immersed to the full depth of the liquid, and the other end connected to the instrument. The instrument consists of a small pot or vessel containing mercury, thus causing it to ascend a suitably arranged scale according to the degree of pressure. The tube from the mercury chamber to the storage tank is connected above the level of the mercury, so that the air pressure passes through the connecting tube to the bottom of the liquid, where it escapes. The pressure at which this happens is proportional to the height or head of liquid above the bottom of the tube. Consequently as the air pressure varies with the head of liquid, the mercury column supported by the air pressure will vary correspondingly. The pressure at which the air escapes is determined by the mercury



LIQUID MEASURING DEVICE.

refusing to rise further into the scale tube. This tube is graduated to suit the specific gravity of the liquid being measured.

It is obvious that this instrument can be placed above or below, or at any distance from the liquid to be measured, and as the connecting pipe contains air only, it is not affected by frost.

The patents in connection with the device are controlled by the Universal Liquid Measuring Devices, Ltd., 125 Isabella Street, Toronto, Ont.

ELECTRICITY FROM BELT SLIP

THAT the unavoidable slight slip of all running belts on their pulleys produces static charges of electricity in these two bodies has often been remarked, and it has sometimes been suggested that this has been the cause of mysterious explosions in powder works. Interest, therefore, attaches to a simple device for removing this charge, described by W. T. Estlick, in the Electrical Review and Western Electrician.

It was used in a textile mill where cotton looms were running with rubber work, so that it was necessary to keep the room perfectly dry. These conditions caused the accumulation of large charges of electricity in the belts of the motors driving the looms, with the result that the belts attracted all the particles of lint floating about, eventually shaking them on to the yarn and making the work dirty. The bits of lint would also gather in the motor, and when this was blown out would settle on the work.

On two occasions also a squirrel-cage motor burnt out, apparently from no other cause than that of the charge in the rotor discharging to earth by sparkling across on to the stator winding and puncturing the insulation. Copper strips connected to earth were then placed above and below the belt, brushing lightly against it. After this no more burning out occurred, and the collection of the particles of lint was also prevented.

SLANDERING OUR SHELL MANUFACTURERS

WITHIN the past few weeks, attempt has been made to discredit the success achieved by Canadian manufacturers of munitions. Information reached us that American manufacturers of machine tools and other equipment were being zealously plied with tales of the tremendous losses being suffered by Canadian shell producers, on account of the unprecedented number of rejections which the Imperial Government had found to be necessary. Since the war started, it has become quite proper to speak in millions—it is so much more impressive. Naturally, then, a million rejected shells of one firm's manufacture made a ready weapon for the detractors of our operative and administrative staffs.

We have taken some pains to prove the truth of the assertion or uncover its falseness, and are now in a position to say authoritatively that there is absolutely no foundation for the statement.

The evident intent of spreading broadcast among American manufacturers the tale that one Canadian firm of itself had a million shell rejections was to create distrust regarding payments for machine tool equipment supplied or on order, and incidentally to hamper not only the maintenance of the production standard we have already attained, but offset further progress and development.

Most people have the impression that shell manufacture as prosecuted in Canada is a profitable undertaking, the suggestion of bankruptcy which the rejection of a million shells portends savors therefore more or less of grim humor.

THE COMMERCIAL PROSPECTS OF NEUTRALS

THAT efforts to skim the cream of European business after the war will be made by all parties capable of doing so, goes without saying, but just how far European nations in general and the Allies in particular will submit to this process is a matter which will be settled by the European nations themselves.

The resumption of ordinary commercial production by our manufacturers will be accelerated according to the rate at which material and labor return to their former basis. That such return will be gradual and perhaps prolonged is more than probable, consequently a considerable proportion of Canada's industrial activity will be available for use in the rebuilding of Europe.

The recent action of the Central States in abolishing the tariff between Germany and Austria will not be overlooked by the British Empire and its associates, and the present union of nations which has been consecrated with the blood of the proudest and best of their manhood may well be expected to have a strength and closeness which will be proof against unlimited exploitation.

In these days it is deeds, not words that count, and if the deeds of powerful neutrals are limited to the laying of plans whereby they may profit from the misfortunes of others, we may rest assured that the plans will meet with just such success as they deserve, no more and no less.

Nations which are able and willing to fight for the rights and liberty of weaker nations are more than likely to see that the credit, thanks and opportunities offered in return are duly received by the proper parties.

The recently announced organization of leading business men in New York for the express purpose of capturing trade after the war seems rather like a case of the wish being father to the thought. That the Allies will be in a state of exhaustion after the war, is without doubt, but that they will allow an onlooker to approach from a place of safety and offer help at a price after the danger has been averted, is most unlikely.

Current events prove that anything worth having must be fought for, and neutrals who anticipate prosperous times as the result of other people's misfortunes may find their overtures appraised at their true value, and received just for so long as they may be acceptable to the parties concerned.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, Que., Dec. 6, 1915.—General conditions are unchanged and the improved situation still continues. Shell-making industries are still very busy and the preparation of plant and equipment for the production of the heavier shells is nearing the stage when machining operations will be in progress. Added to the former duties of the old Shell Committee, the distribution of orders for the other allies may be placed in the hands of the newly organized Munitions Committee. This continent, and particularly Canada, is now more than ever placing herself among the older nations of the world in the supplying of necessities for foreign consumption. That we will retain our position following the war is generally conceded, but to maintain this place which present circumstances have almost forced upon us, there must needs be no cessation of effort. The cessation of hostilities is sure to usher in an era of prosperity and we must be prepared to take our proper place in the re-constructed distribution of trade between the Eastern and Western hemispheres.

Many lines of activity have been opened to Canadian manufacturers which a year or two ago were almost unknown. The chemical industry has been revolutionized in the past year and remarkable strides are being taken in the production of what a few years ago were the secrets of European nations only.

The manufacture of high-speed and special steels are also receiving attention. Again, many firms have branched out into the manufacture of machinery and other utilities which for decades had been solely monopolized by Austria and Germany. During the winter and spring shipbuilding will receive much attention provided the necessary steel for construction can be obtained. The prospects for the coming winter are brighter than a year ago, and the cry of the unemployed will be less heard than in previous times.

Pig Iron

Producers are still striving to keep up with the pace being set by the steel manufacturers and are on the whole very successful. Production still continues with unabated energy. Market prices in the States show advances, but local conditions remain unchanged.

Steel

The unsettled state of the market still continues with prices advancing steadily. Quotations made to-day may not be in force to-morrow, and price lists are no longer to be relied upon. In some instances steel for war munitions is booked a year in advance, and with the mills producing maximum capacity in the majority of cases it is apparent that little opportunity is imminent for the supply of steel shapes and bars for domestic purposes. The latter begins to assume greater importance than a few months ago indicated.

What the situation will be in a short time is at present difficult to determine, but that prices will advance still further is quite evident. Some of the large producers in the States have refused large export orders for plates and bars, even at a price much higher than that now quoted, and with the possibility of foreign countries requiring large shipments of steel from this continent, for several years to come, the conclusion is that the current high prices will be maintained for an indefinite period.

> **CANADIAN GOVERNMENT PURCHASING COMMISSION**
>
> **The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.**

The market in steel bars, plates and structural shapes is very active and prices are advancing daily. Bars show an increase, and are now quoted at 2.55 cents per pound. Shapes are 2.30c, being an advance of one-tenth cent per pound. Plates are also strong at 2.30c. Boiler heads have advanced and this week's quotation is $3 per hundred pounds. Lap-welded boiler tubes have taken another jump and an advance of 6 to 10 per cent. is noted in this week's list.

Machine Tools and Supplies

Added to the already high pressure being placed upon the machine tool builder for the output of shell making machinery, are the inquiries that are now coming in for equipment for the production of domestic specialties. Complaints are still being received from customers regarding delivery on certain machines ordered months ago, and now long overdue. The return of normal conditions in industrial spheres outside of those bearing on the war situation is tending to create a high optimistic outlook, and the prospects for the coming year are that the machinery trade will maintain for a long time its present activity. All lines of the metal working trade are more or less affected by the scarcity of high-speed steel, and in some cases very abnormal prices have been offered for this much-needed accessory to finished production. High-speed steel is quoted from $2.50 up. Supplies of all kinds are still in demand with prices firm.

Metals

The close approach of the end of the year finds the market in a quiet and inactive condition, and the prospects for the remainder of the year are that little change need be looked for. The feature of the week has been the unstable position of spelter, this being the outcome of speculators trying to deceive the market.

Copper.—Very little activity is noted in copper; the market is dull with prices holding firm. Foreign markets in some quarters are showing weakness while others appear stronger.

Tin.—The present state of the market shows plenty of tin on hand; in fact, the visible supply is in excess of the demand. Reports of the sinking of vessels in the Mediterranean, one or more of which may have cargoes of tin aboard, has created some excitement among buyers. However, unless these reports should be followed by increased activity among the dealers, no advance is looked for. The local market for the past week has been dull and a decline of $20 a ton is quoted, the price this week being 45c per pound.

Spelter.—The sand foundation upon which the spelter market has been resting for the past few months is beginning to totter. Owing to speculation on the part of large buyers and also the holding back of available supplies by producers the situation at the present time shows some signs of demoralization, and a decline in prices is daily expected. Quotations in foreign markets are showing sharp declines, and it is anticipated that local dealers will follow suit shortly. Last week's prices prevail at 20c per pound.

Lead.—Little change is noted in the position of lead over that of last week, and the market is quite dull, with a tendency to decline. No change in price has taken place in local markets and dealers are quoting $6.75 per hundred.

Antimony.—Local dealers are quoting last week's prices, but the market generally is showing weakness and a decline is looked for any time. Inquiries are fairly good at 42c per pound.

Aluminum.—Increased demand for aluminum has advanced the price this

week and dealers in this district are asking 65c per pound, being an increase of 3c.

Old Material.—The scrap metal market continues to retain a steady tone, and prices are holding firm. Dealers report good business in copper and heavy melting steel, with prices unchanged. The general situation remains the same as last week with the exception of scrap zinc, which is weaker, being now quoted at $12.75. Scrap aluminum is very strong at 27c per pound, with little on the market.

Toronto, Ont., Dec. 7.—Industrial conditions continue to show a decided improvement and a better feeling prevails in business circles. The success of the war loan is gratifying, and, representing a response far ahead of expectations, it cannot help but stimulate the returning confidence of the public generally in the financial and business outlook. The trade returns issued by the Department of Trade and Commerce for the month of November show an increase in revenue of over 7½ million dollars over that of November, 1914. The total revenue for November, 1915, was just over 17 million dollars, and the largest of any month in the history of the Dominion. For the eight months of the present fiscal year ending Nov. 30, the total revenue aggregates $104,750,000 as against $90,400,000 for the corresponding period in the last fiscal year.

The steel trade continues very active and the mills, although operating at capacity, are getting behind on deliveries. Forging plants and machine shops are getting behind on deliveries. Forging plants and machine shops are also working at full pressure and preparations are being made to handle the large shells. Machine tool builders are very busy turning out machines for shell plants. Prices of all machinery is advancing due to the increased cost of raw materials. There is a good demand for ingot metals for munitions, but the market is dull and weaker. Tin and spelter are lower.

Steel Markets

The market is very firm and prices have a higher tendency all round. The volume of business being done is larger than it has ever been and the mills are unable to meet all the demands. The steel companies are booked up for months ahead, pricipally on tonnage for shells, although a large export business is being done in other lines of steel products. The steel trade is passing through a period of prosperity, the like of which was never before experienced. The steel companies, although working night and day, cannot keep pace with the demand and are therefore getting behind on deliveries. The demand for steel for shells is taking the capacity of mills to the limit, but plants are being extended to take care of the increased business.

Prices on finished and semi-finished steel products are very firm, with a higher tendency for most lines. A few advances have to be noted such as lap-welded boiler tubes, wood screws, wire nails, cut nails, grey forge pig iron and Lake Superior charcoal iron. Warehouse prices for Pittsburgh bars, etc., are higher. Steel bars are still being quoted at 2.75c and iron bars at 2.50c, but higher prices are expected in the near future. Wrought iron pipe is very firm and may go higher. Smooth steel wire has advanced 15c and is now quoted at $3 base. Pressed steel spikes ⅝ in. diameter, have advanced to $3.25 per 100 lbs. Prices of Pittsburgh bars, plates and shapes are still withdrawn and the situation is unchanged.

The situation in the galvanized sheet trade does not improve. Manufacturers are handicapped by the shortage of steel, the scarcity of sulphuric acid, and high price of spelter. Prices of galvanized sheets are very firm at the advance announced last week, and there is a probability of further advances. Prices of black sheets are strong and are slowly advancing. Black No. 28 gauge are quoted at from 2.40c to 2.50c, Pittsburgh base. Blue annealed No. 10 gauge are quoted at from 2.15c to 2.25c, Pittsburgh base.

In the United States market, the advance in prices continues and the difficulties of quoting the market are increased by the inability of many producers, particularly on billets and wire rods, to take any of the business offered. As regards buying of shell steel, deliveries reaching to November, 1916, are now being considered in connection with business from one country in Europe. The market for large rounds is very strong, but rather less active.

Other small steel bars are still being quoted at 1.70c Pittsburgh, but this figure is more or less nominal, 1.80c being nearer the market, Pittsburgh. Buyers of billets are experiencing considerable difficulty in getting their needs supplied. There is a big demand and the scarcity is getting more acute. Prices continue to advance. Bessemer billets are now quoted at $29, open-hearth billets at $30, and forging billets $52 base, f.o.b. Pittsburgh. Steel hoops have advanced to 1.90c Pittsburgh.

Pig Iron

The market continues very strong and prices of all American brands of pig iron have advanced. It is reported that a shortage of iron is threatened, particularly at Buffalo. All quotations on charcoal irons have been withdrawn by the principal Lake Superior district producing interests. Lake Superior charcoal iron has advanced to $17.75 Chicago, and grey forge to $16.95 Pittsburgh. Hamilton and Victoria brands are firm but unchanged at $23 per ton.

Machine Tools

The situation in the machine tool market is unchanged. Dealers are very busy figuring on shell equipments and have lately sold a number of lathes for machining 6-in. shells. An interesting feature in the trade is the development of special machines for making shells and shell parts. This work is keeping a number of smaller machine shops actively employed and the larger concerns are also very busy turning out machinery for making shells. Machine shops continue to work at full pressure, both those making shells and those making machinery for shells.

Supplies

The active demand for machine shop supplies continues and business is very brisk. Prices generally are very firm. Milling cutters have advanced again, and are now practically 150 per cent. higher than they were 12 months ago. There is no improvement in the high-speed tool steel situtaion and prices now range from $2.85 to $3.05 per pound. Tungsten is still very scarce and prices continue to advance. Gasoline, benzine, turpentine and linseed oil are all very firm and higher prices are expected.

Old Materials

The market generally has a weak tendency, but prices are unchanged, except for No. 1 wrought iron, which is stronger and has advanced to $9.50. Heavy melting steel is in good demand, as also are the different grades of copper.

Metals

There is an easier tendency in the market this week and both tin and spel-

---

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Messrs. S. Ruperti and Alexsieff, care Military Attache, Russian Embassy, Washington, D.C.

ter have declined. The tin market is dull in London, the weakness being attributed to the increase in visible supplies. The spelter market appears to be demoralized in New York, following a decline in London. The copper market is quiet and prices nominal. There is no change in lead and the market is dull. Antimony has an easier tendency and aluminum is also unchanged.

Tin.—The tin market continues to decline to a more normal basis. The recent sharp advance was quite unwarranted and the market will no doubt get back to the price prevailing immediately previous. The visible supply is increasing and there is less fear of any shipments being lost through submarine operations. The local market is weak and has declined 1c. tin being now quoted at 45c per pound.

Copper.—The local market is very quiet and will probably remain in this condition for the next two or three weeks. The recent buying movement has died down and the tendency will be for consumers to stay out of the market for the balance of the year. The market has become a purely nominal one and quotations are unchanged at 20¾c per lb.

Spelter.—The market is demoralized in New York, and there is a lack of support on the part of the large interests. The market has been following London and a sharp drop there affected New York. Buyers are holding off and prices are nominal. Spelter is weak locally and has declined 1c, being quoted at 20c per pound. Zinc ore is quoted from $100 to $115, Joplin, Mo.

Lead.—The market is dull and featureless, the "Trust" price of 5.25c being still held at New York. Local quotations are unchanged at 7c per pound.

Antimony.—The market is dull and prices remain about the same on all positions. Antimony is unchanged locally at 40c per pound.

Aluminum.—The market is easier, but prices are unchanged. Supplies of aluminum are coming in rather more freely, which will have a tendency to weaken the market. Local quotations are unchanged at 65c per pound.

Solder.—The market is weaker following the decline in tin, and prices have declined. Solder, "half-and-half," is now quoted at 24c per pound.

WINTER MAIL PORT CONTROVERSY

IN the annual controversy between Halifax, N.S., and St. John, N.B., as to their respective merits as winter ports, a letter written by Sir Thomas Shaughnessy, president of the Canadian Pacific Railway Co., is taking a very important place this year. The letter was in reply to one from Sir Robert Borden, who had placed before Sir Thomas Shaughnessy telegrams and letters from the Halifax City Council and Board of Trade registering strong protests against sending the Corsican and other mail ships to St. John without calling at Halifax. The letter of Sir Thomas Shaughnessy to Sir Robert Borden reads as follows:—

"I wish that it were possible to comply with your request to have our passenger ships call at Halifax on the inward and outward trips this winter, but, as I said to you personally, I am convinced that it cannot be done in the interest of the country.

"The war has brought upon us a condition of things with reference to our Atlantic steamship service that could not have been foreseen, and that it will be difficult for us to satisfactorily meet, even with out greatest efforts. As you know, a great many of our ships have been taken by the Admiralty, and we have found it impossible to charter a sufficient number to replace them.

"In these circumstances we must either utilize such steamships as are available to the utmost, or we must permit a substantial percentage of our Canadian exports to be diverted from Canadian ports.

"Apart from all other considerations, the Halifax call would involve a delay to our passenger ships of from two or three days on each round voyage, with a like reduction in their freight carrying efficiency. Our endeavor must be this winter to avoid unnecessary detention of a single hour, so as to secure the fullest advantage of their carrying capacity. By running direct to and from St. John, in these exceptional circumstances to which I have referred, no precedent is being established.

"When normal conditions return, the Halifax mail service and the terms upon which it is to be conducted will be open for consideration."

CANADIAN PURCHASES FOR FRENCH WAR OFFICE

Philippe Roy, General Commissioner for Canada, Paris, advises the Department of Trade and Commerce, Ottawa, that an order has been issued by the War Department of the French Government to the effect that all purchases made by the Supply Branch in Canada will pass through the Hudson Bay Co. Canadian producers should therefore submit their future offers through the office of that company at Montreal. It is further stated in Mr. Roy's communication that Canadian lumber, steel and meat will find in France an important market for years to come, but it is necessary that Canadian firms should have in Paris representatives entrusted with the necessary authority, especially if it is desired to secure Government contracts.

REMEMBERING EMPLOYEES AT THE FRONT

ARTHUR MARSH, brother of Lt. Col. Marsh, president of Marsh & Henthorn, Belleville, Ont., and Bombardier Ed. Blaylock, a member of the office staff, who spent last Christmas in Salisbury Plain Camp, and who knows the needs of the soldiers at the front have prepared a large number of Christmas boxes, weighing the limit of eleven pounds each, one for each former employee of the firm now on active service. The firm and the entire office and munition staff contributed to the gifts. Each man gets a box containing the following:

Three plugs 10c "Prince of Wales" chewing tobacco.
One 30c plug "T & B" smoking tobacco.
Fifty "Sweet Caporal cigarettes in tin box.
One 25c pipe.
Two small boxes safety matches.
Five packages chewing gum.
Five packages chocolate.
One box "Lifebuoy" soap.
One pad writing paper.
One bundle envelopes.
One pencil.
One tin of sardines.
One tin of condensed coffee.
Half-pound tin Brazil nuts.
Half-pound of shelled walnuts.
One package of dates.
Twenty-five cent tin "Oxo."
One tin of "Paris" pate for sandwiches.
One Christmas cake, 1½ lbs.
One package butter scotch.
One steel mirror in case.
One tin insect powder.
One tooth brush.
One pair leather mitts, oil tanned.
One pair 50c socks.
One package bachelor's buttons.
Two handkerchiefs.
One hand towel.

The men who fire the munitions will certainly be deeply appreciative of the thoughtfulness of their comrades who are making the shells.

NOVEMBER REVENUE A RECORD

THE war budget is giving results exceeding the most sanguine expectations of the Minister of Finance. The total revenue for the month of November is $17,072,456.76, an increase of $7,576,-920.46, over that of November of last

year, and the largest for any month in the history of the Dominion.

For the eight months of the present fiscal year, ended November 30th, the total revenue aggregates $104,750,000, as against $90,400,000 for the last fiscal year, when, owing to the effect of the war, trade was badly demoralized during August, September, October and November, of the eight months in question. The estimate of the Minister of Finance that his budget of February last would realize thirty millions of additional revenue is not certain to be substantially exceeded.

The policy adopted by the Government at the outbreak of the war of proceeding only with works actually under contract is now bearing its full fruit. For the first eight months of the current fiscal year the ordinary expenditures show a reduction of over ten million dollars, and the capital expenditures of about three millions. Between increased revenue and decreased expenditure the financial position this year as compared with the previous year shows a favorable balance of twenty-seven million dollars. The Dominion is thus daily becoming stronger to meet the increasingly heavy expenditures of the war.

CANADA'S WAR LOAN

THE Government has decided to make the Canadian War Loan one hundred instead of fifty millions. The extra fifty millions will be obtained from the sixty odd millions of the over-subscriptions to the original loan, and will be used as a credit for the Imperial Treasury to pay for shells, munitions and other war supplies ordered by the Imperial Government.

It is the first step towards doing Canada's fair part in helping the motherland to finance the enormous war expenditure of $25,000,000 per day, which the Imperial Treasury has hitherto borne unaided. It means that the Government has definitely embarked on the policy on helping the motherland not only with men and munitions, but also with money, and of returning, in part at least, the assistance which the Dominion has received from Britain in the way of war loans and through half a billion dollars' worth of war orders. Later on, when the first fifty millions of advances to the Imperial Treasury are exhausted, the Government will "devise a plan whereby with the co-operation of the chartered banks a further credit for the same purpose will be created."

Before the war is over the extent of this financial aid to Great Britain is likely to amount to $300,000,000 or more—all of which will eventually be paid by the motherland, and is being immediately paid in the shape of war orders, which are keeping Canadian industries busy.

C.P.R. PURCHASES FOR BRITISH GOVERNMENT

THE C.P.R. is providing the British Government with war necessities ranging over a wide field. Excluding horses, fodder, ammunitions and munitions, there is hardly anything that could be mentioned that the company is not interested in purchasing, if it can show relation to the needs of the military in the field. The amount ordered at first was small, because the British authorities did not know to what extent Canada could supply the articles needed. In fact the orders at first did not total $500,000, but when Sir Thomas Shaughnessy went over to England and consulted with the authorities he was able to inform the latter as to the aptitudes of our Canadian manufacturers.

The orders include millions of pairs of socks and drawers. Shovels and spades are in much demand by the military authorities on the other side, with whom the C.P.R. deals entirely, placing its experience at the disposal of the British War Office, in a spirit of patriotism, rather than in that of a huckster. Handled axes have been in great demand; and the country has been scoured for them. Wire cable was badly needed, and hundreds of miles of it have been ordered by the C.P.R. department. Rubber boots of the full hip pattern, snowshoes, cheese, safety matches, shoepacks, evaporated vegetables, including potatoes, which are in great demand, etc.

Cement sacks were secured from the Canada Cement Co., to the number of 8,000,000 chisels, screw-drivers, vises, brass drills, shears, augers, punch cutters, helmets, etc.; in fact, there is nothing which could be included in the necessary outfit of troops in the field which is not in demand.

The British authorities could take many more things which Canada does not, as yet, manufacture, but the C.P.R. has focused every manufacturing interest in the country on Room 114, on Windsor street—a room which displays no sign, hints no business, but in which are thousands of samples, and always a large number of manufacturers, or their agents, for the company deals direct.

To date more than five million dollars' worth of goods and materials have been purchased.

BANKERS DISCUSS MUNITIONS' FINANCING

THE Minister of Finance on Dec. 2, conferred with a Committee of the Canadian Bankers' Association whom he had invited to Ottawa to discuss with him the extent to which Canada might assist in the partial financing of Great Britain's expenditure for shells, munitions and supplies in Canada, and the means by which such assistance could be best afforded.

It is understood that such methods as the issue of Dominion notes against gold deposited in London, acceptances of bills of exchange and advances to manufacturers and others against Treasury bills or other securities, were discussed. It is believed that the Minister of Finance has in mind a plan which will materially assist in the financing of the purchases in Canada by the Imperial Government during the next six months or year.

The suggestion has been put forward frequently since the outbreak of the war that Canada should finance her own war expenditures in their entirety, as well as the purchases of Great Britain and the Allies in Canada. The following figures show the nature of the problem.

Canada's war expenditure from the outbreak of the war until December 31st, 1916, will probably amount to $400,000,000. The purchase of Great Britain and the Allies of supplies and munitions will probably by that date have exceeded $600,000,000. The total of Canada's war expenditures and purchases by the Allies will thus be over one thousand million dollars. Up to the outbreak of the war Canada had been, and is still a borrowing country, depending upon outside money markets for the sale of her Dominion, provincial and municipal securities.

As Canada has no international money centre like New York or London, where accumulations of capital are available for short-date Treasury loans or for the sale of Government securities, it is obvious that Canada will not be able to provide funds for the whole, but for only a part of her own war expenditure, and by way of advances for the expenditure in Canada by the Allies for supplies and munitions. Only by production and saving is it possible to increase the supply of Canadian capital available for this purpose.

Laurentide Power Co. Board.—J. E. Aldred, president of the Shawinigan Water & Power Co., and Cedars Rapids Power, has been chosen as president of the Laurentide Power Co., while F. A. Sabbaton was elected vice-president. The other members of the board include Edwin Hanson, C. R. Hosmer, George Chahoon, jun., J. H. A. Acer, Howard Murray, Julien C. Smith, and Secretary-Treasurer W. F. Robinson. One vacancy on the board remains unfilled, and it is held for a representative to be named by the Shawinigan Water & Power Co.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

St. Mary's, Ont.—C. Richardson & Co. are equipping a plant for making shells.

Hamilton, Ont.—The Tallman Brass Co. are making an extension to their plant.

Toronto, Ont.—The Multipress Co. is in the market for drop hammer and screw presses.

Lachine, Que.—The Dominion Bridge Co. are building a brass foundry at a cost of $20,000.

Hamilton, Ont.—The Acme Stamping Tool Works will make an extension to their plant to cost $3,000.

Toronto, Ont.—The Chapman Double Ball Bearing Co., have started work on a further addition to their plant.

Blenheim, Ont.—The Pere Marquette Railway Co. may instal a pumping plant here, taking water from the River Eau.

Wallaceburg, Ont.—The Wallaceburg Brick Co. will erect an addition to its plant and will install machinery for the manufacture of tile, etc.

Waneta, B.C.—The Waneta Development Co. will construct a hydro-electric power plant at the Columbia and Pend O'Reille Rivers, B.C., to have a capacity of 80,000 h.p.

Peterborough, Ont.—The Peterborough Metal Products Co. will take over the premises formerly occupied by the Canadian Cordage Co., and will install machinery for manufacturing metal products.

Englehart, Ont.—A representative of the Riordan Paper Mills of Montreal, has closed a deal for the old Foster Mill at Haileybury, and are placing new machinery in it for rossing the pulpwood they expect to purchase in Temiskaming.

Welland, Ont.—The Canada Forge Co. will build an extension to their plant. The new building will have an area of 180 x 80 feet, and will be of structural steel. The cost is estimated at $20,000, and the equipment to be installed will cost $100,000. T. J. Dillon is manager.

Ottawa, Ont.—A private concern, the Transcona Shell Company, will make shells in one of the several extensive shops of the Transcontinental Railway, near Winnipeg. The G. T. P. some time ago secured a contract, but has since transferred it to the Transcona Shell Co. It is understood that Montreal capitalists, headed by Sir Edward Holt and Henry Timmins, are interested.

Municipal

Otterville, Ont.—A hydro-electric system will be installed here to cost $2,150.

Lambeth, Ont.—The town will construct a pump house and install new machinery.

Huntsville, Ont.—The town council will build a sub-station and improve the power plant and distribution system.

Sarnia, Ont.—The City Council have decided to lay an intake pipe from the third basin of the Point Edward plant out into the lake.

West Lorne, Ont.—It is proposed to spend $8,000 on a hydro-electric power system. A by-law will be submitted to the ratepayers on December 20.

Sherbrooke, Que.—The city council are considering alterations and improvements to the water power, electric transmission and lighting plants.

Edmonton, Alta.—The City Council contemplate spending $274,967 on a sewage disposal plant. A by-law will be submitted to the ratepayers on Dec. 13.

Springfield, Ont.—A by-law will be voted on by the ratepayers on December 9 to authorize an expenditure of $5,000 on the installation of an electric light plant.

London, Ont.—It is announced that owing to the increase of the consumption of hydro power the rate charged London by the Ontario Commission would be reduced January 1 from $24 to $22.

Cornwall, Ont.—The town will purchase a new pump and make extensions to its waterworks system to cost $25,000. A by-law will be voted on by the ratepayers on January 3.

Sarnia, Ont.—The city contemplate improvements and extensions to the water distribution system. A by-law will be voted on to sanction the necessary expenditure, which is estimated at $12,000.

Berlin, Ont.—The City Council have decided to submit a hydro-radial by-law for $779,000 to the ratepayers. Waterloo Town and Waterloo Township Councils also voted in favor of submitting similar by-laws, the former for $193,000, and the latter for $521,903.

Winnipeg, Man.—City Engineer W. P. Brereton has recommended the installation of two gas engines at the high-pressure plant on James Ave., to be used to develop electrical energy sufficient to operate two 5,000,000 gallon motor-driven booster pumps at the McPhillips street pumping station. The cost of this stand-by arrangement would be $21,000.

General Industrial

Windsor, Ont.—The Vacuum Street Cleaning Machine Co. are considering the building of a factory in this district.

Fort Erie, Ont.—The International Safe & Register Co., contemplate the erection of an addition to their factory shortly.

Nelson, B.C.—Donald Fraser, Ltd., Fredericton, N.B., have commenced the re-erection of their sawmill on the Miramichi River.

Hamilton, Ont. — The Proctor & Gamble Co., soap manufacturers, have had plans prepared for an addition to their factory.

Toronto, Ont.—A fire last Friday damaged the Gold Medal Furniture Mfg. Co. factory to the extent of $100,000. W. J. McMurtry is the manager.

St. Catharines, Ont.—The Marathon Rubber & Tire Co. have begun the erection of a factory, and expect to have the plant in operation by the first week in March.

Saskatoon, Sask.—The Alaska Bedding Co., of Montreal and Winnipeg, have purchased the entire plant of the Stamco Mfg. Co. The building has been taken over by the T. Eaton Co., and the Alaska Bedding Co. will store the machinery until the spring, when it will probably be utilized.

Moose Jaw, Sask.—Two large manufacturing concerns, one of Vancouver, B.C., and the other in Iowa, are looking at Moose Jaw favorably at the present time, as a most suitable city in which to establish branch factorires. The Vancouver firm is interested in the manufacture of brushes and brooms, while the Iowa firm manufacture fountain pens.

Large Shells: Production Problems and Possibilities---V.

By C. T. D.

In preparing to undertake the production of large shells up to 9.2 in. dia., manufacturers will encounter problems of a nature altogether different from those connected with 18 pdr. shells. Automatic machinery will not be so applicable to the larger sizes, and productive ability will centre largely on such points as sequence of operations, tooling methods, etc.

ALTHOUGH the majority of manufacturers who have undertaken the production of large shells are already operating plants of more or less magnitude, they are more than likely to find that a considerable number of new machines will be necessary in order to maintain deliveries. Those firms who are already established, especially in lines of a general nature, will lean towards the adoption of machines which possess features and quality of more than temporary interest. The increased industrial activity which is ultimately expected justifies the selection of machine tools which can be expected to continue rendering good service for years to come.

Machines of this class have been produced by several makers during past years, which, although primarily adapted to munitions manufacture, are of considerable value as producers in establishments of the class referred to.

The installation of such machines at the present moment, while initially more costly, is ultimately a double economy, because, firstly, they are the result of many years' experience by large organizations, who have made a success of work of this kind. They have been tested out under months and years of severe service, consequently their makers can supply them with the assurance of immediate production without that experimenting which has so frequently to be done when one is operating along new lines. Secondly, when their work on war material is finished, their sound design and first-class construction give them a high permanent market value, whether they are retained in a factory or offered for sale.

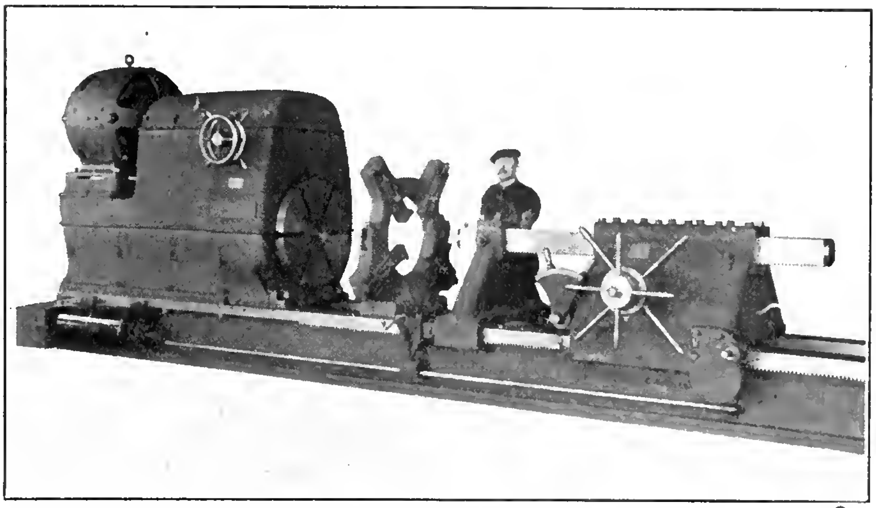

FIG. 15. PROJECTILE BORING LATHE FOR SHELLS FROM 6 IN. TO 12 IN. DIA.

For many years the John Bertram & Sons Co., of Dundas, Ont., have specialized in the building of machine tools of the highest grade for many lines of engineering work, and their activity in providing equipment for munitions plants has been characterized by all the features of their normal efforts.

The accompanying schedule of operations suggested by them is based on use of machines which have been developed specially for large projectile work, yet have that value for other lines which appeals to the fore-armed manufacturer. Minor operations are performed on existing types of machines which call for no special comment.

Comparing these operations with previous suggestions, the principal feature observed is the thoroughness of the methods adopted. For instance, when finish turning the body in the fifth operation, the shell is mounted on a special arbor which extends through the nose, thus insuring absolute concentricity between inner and outer surfaces. While the careful performance of previously published methods on miscellaneous machines would produce work of the required accuracy, the absolute certainty of these methods ultimately results in greater output.

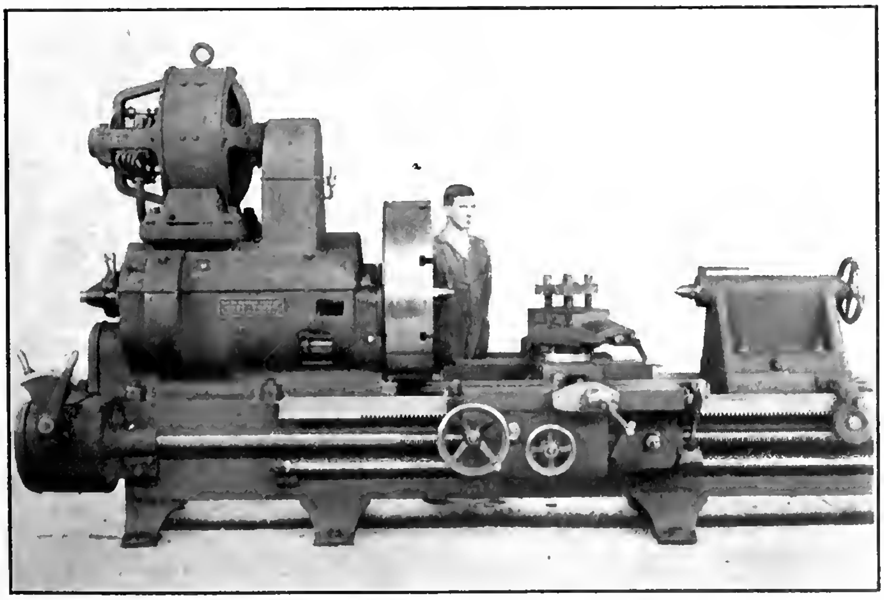

FIG. 14. 36-IN. MOTOR-DRIVEN LATHE FOR TURNING LARGE SHELLS

Illustrations of the principal machines referred to are shown in Figs. 14, 15 and 16. Fig. 14 shows the 36 in. heavy duty engine lathe used for the third operation. While of seemingly conservative design, this machine has several features which call for more than passing mention. The strain of constant heavy cutting on rough forgings demands more than ordinary stiffness, and both the main spindle and the tailstock spindle are supported in such a manner as to insure the desired rigidity. The drive is from a variable speed motor, with a minimum amount of gearing, which is entirely enclosed. The headstock is of box form, the side walls imparting considerable added stiffness to the spindle bearings.

A very liberal amount of bearing surface is provided for the carriage, while the attention given to such important

details as lubrication and the provision of dust scrapers to prevent the entrance of cuttings beneath the carriage are points which appeal to the judicious purchaser.

The machine which is of the most immediate interest at the present moment is the heavy projectile boring lathe, shown in Fig. 15. This machine swings 36 in., and is suitable for rough and finish boring projectiles from 6 in. to 14 in. diameter. The design throughout is of a most substantial nature. The bed sits flat on the foundation over its entire length, flat tracks and large cross section being prominent features in the design.

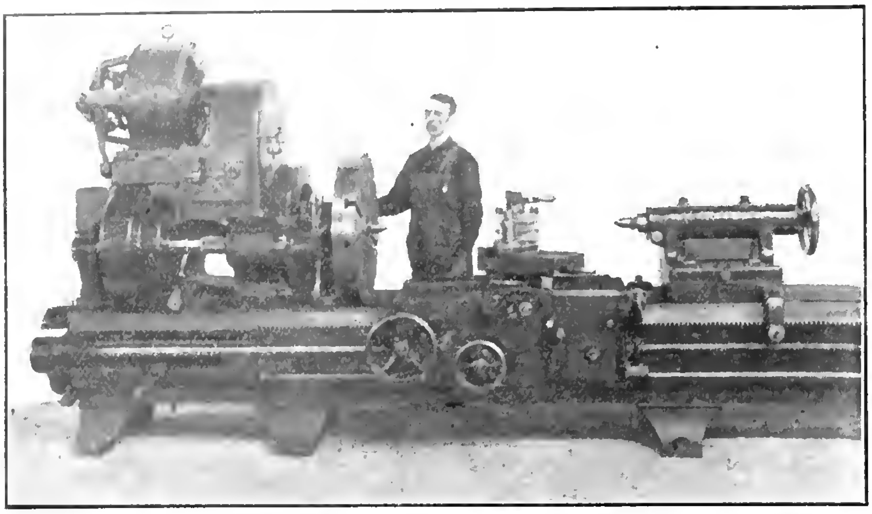

FIG. 16. 30-IN. ENGINE LATHE FOR GROOVING AND BAND TURNING.

The headstock is of box construction, with all gears enclosed, the direct connected motor being mounted on a pedestal above the rear bearing. The front spindle bearing is 8 in. dia. x 23 in. long, these dimensions conveying some idea of the liberal proportions throughout. The bearings and gears, which are entirely enclosed, are lubricated continuously from a high level tank contained in the head, the oil being constantly pumped up from the bottom of the headstock.

The 35 horse-power motor is of the variable speed type, and the gearing through which it drives gives three mechanical changes controlled by handwheels. The electrical control of the motor gives 20 variations, which, combined with the gearing, gives 60 different face plate speeds from 2½ to 77 revs. per min. The control shaft extends along the front of the bed, and the con-

Sequence of Machining Operations for 9.2 in. Howitzer Shell Forgings.

Drill Center Hole and Face Nose of Shell

Performed by heavy radial drill. The shell is dropped over an arbor which fits the shell, and which is located central with drill spindle. The twist drill used is a little smaller than the size of the bottom of the thread in the nose, enough stock being left to make a reaming operation. After the hole is drilled twist drill is taken out, and a pilot facing cutter is used, which sweeps off the nose end of the shell, giving a flat surface, a little larger than is required for the finishing end.

Cutting-Off the Open End

For this operation heavy cutting-off machines are used, the shell being held in the spindle of the cutting-off machine, back against a stop, or in some cases a heavy engine lathe is used, to the face-plate of which is attached a heavy split cast iron chuck, open end of which runs in steady rest.

Rough Turning Forgings

This operation is performed on 36" heavy duty engine lathe, and the open end of the shell is placed on an expanding arbor which grips the inside bore, the tailstock having a revolving center, fitting in the hole already drilled in operation 1. This machine is arranged with a profiling attachment, so that the roughing cut will turn the outside of the shell to shape.

Boring Out the Shell

This operation is performed on a 36" projectile boring lathe, which is motor driven. To the faceplate of the lathe is bolted a heavy cast iron split chuck, which is supported on the outer end, by heavy steady rest. The shell is slipped into the chuck, and clamped in position. The projectile boring lathe has a heavy square steel bar running through the tailstock, and is driven by all steel gearing, and has sufficient power to carry a three fluted roughing reamer, each cutter of which has serrated edges for breaking the chips. After this cutter is driven in the desired depth, it is withdrawn and the second cutter bar takes its place. The second cutter bar is of acorn shape, having two high speed steel cutters of the desired shape to finish the internal bore of the shell. This operation demands a heavy machine, as while the operation is performed in a comparatively short time, the character of the work must be perfect.

Finish Body Turn

This operation is performed on a 30" heavy duty engine lathe, the shell being mounted on a special arbor, conforming to the inside diameter of the shell, with the arbor extending through the shell, and held in position by nuts on either end of the arbor, which is driven from the faceplate. The lathe is provided with a special forming attachment, which enables the operator to not only turn the outside diameter of the shell to an exact size, but also gives a perfect form to the nose of the shell.

Boring and Threading the Nose

For this operation 26" heavy duty lathe is used, the large end of the shell being held in chuck bolted to faceplate of the lathe, and body of the shell running in steady rest. The lathe is provided with a turret on the carriage, enabling the use of a number of tools in rotation for this operation, the hole being reamed out to the proper size for threading, the nose of shell being faced to a finish, the thread being cut by collapsible tap, and a tool being used of suitable shape to face up the inside of the shell back of the thread.

Waving and Undercutting

A 30" heavy duty lathe is used on this operation, or special lathe of heavy design, equipped with a waving and undercutting attachment. This attachment consists of a fixture bolted to the bed of the lathe, and having at the back two tools operated by cams which remove the stock and undercut the corners. The front tool on the fixture has the required number of depressions for the number of waves required, and is operated by a cam on the faceplate which completes the form, giving the waving motion required.

Counterboring and Threading the Base

A heavy duty 30" lathe is used having a large cast iron split chuck secured to the faceplate, with the open end running in steady rest. On the cross-slide of the lathe is located a heavy turret with the necessary tools required for the counterboring operations and facing of the end of shell. The threading is performed by a chaser of the desired pitch, which requires a number of cuts to cut the thread to the desired size.

Pressing the Copper Band to Place

The band being heated is slipped over the shell, and forced into the groove prepared for it, either in a steam hammer, by means of two half circle dies, a few blows only being required to force it into its place, or by an hydraulic press, either method giving very good results.

Turning the Copper Band

This operation is performed on a 30" heavy duty lathe, with special attachment, or a single purpose lathe with special attachment, the tool of the attachment roughing the copper band to an approximate shape, and the other tool finishing the band to an exact size and shape. To the fixture carrying the finishing tool is a special attachment for undercutting the copper band to suit the specifications.

Facing the Base Plug in Position

The base plug being screwed in place, the shell is then chucked in heavy duty 26" lathe, having a split cast iron chuck bolted to the faceplate, open end of which runs in a steady rest. The base plug having been left a little thicker than the depth of counterbore in the shell, the surplus stock is then removed, giving a perfectly flat surface on the base of the shell.

Turning the Base Plug

The base plug is a drop forging of suitable size with ample stock for finishing operations. The forging is chucked, faced and turned to the proper diameter, then threaded to an exact size, leaving the large diameter a little longer than is required to fill the recess in the shell, this surplus stock being taken off as stated in operation 11.

After the above operations have been completed, having been inspected at intervals during the process of manufacture, it is then necessary to varnish the inside and bake same. This leaves a perfect glass-like surface for the high explosive. Before shipment the shells are painted with vaseline, to prevent them from rusting. The work throughout has to be of a very high character, in order to suit the requirements, and conform to the specifications insisted upon.

trol handle is carried by a bracket, which can be moved along the bed as desired, giving complete control over the motor from the position most convenient for the operator.

As boring operations form almost the entire work of this lathe, special provision in the shape of a self-oiling roller type thrust bearing has been provided to prevent trouble under continuous heavy duty.

The tailstock is designed to carry a square boring bar of generous proportions, and made from a steel forging. The bar is fed forward by a pinion engaging with a rack on its underside. The feed shaft extends along the back of the bed. Mounted on the back end of the rack pinion shaft is a large worm wheel, the worm which drives it being driven from the feed shaft through a small train of spur gears.

The movement of the bar is controlled by suitable cutters, which are fed straight into the forging, the travel of the boring bar being in a straight line only.

The engine lathe shown in Fig. 6 is a 30 in. double-geared type, suitable for performing the various operations involved in grooving, waving and band-turning or forming. Although not of such massive design as the lathe shown in Fig. 14, it possesses all the elements of rigidity, the tailstock being liberally proportioned and securely bolted to its base block.

The four-sided tool post, shown in the illustration, is that which is ordinarily supplied. When equipped for grooving and waving, a special rest is substituted, consisting of a lower slide, which is mounted directly in the carriage, and has cross adjustment by a hand screw. A tool slide is mounted on this lower slide.

band lathe, the drawing showing the arrangement for the 9.2 in. shell.

The bearings are cast integral with the bed, and are of large size, the front one being $9\frac{3}{4}$ in. dia. x 7 in. long, and the rear 6 in. dia. x 7 in. long. Both bearing caps are machine fitted, and secured by four heavy studs, the forward cap being interlocked with the bearing to take the end thrust without end shift. Bearings are babbitt-lined and provided with shims for taking up wear.

The tailstock is a very rugged casting, located and bolted to the bed to suit the size of shell being machined. The spindle is 5 in. diameter, finished by grinding, and holds a heavy centre fitted to a No. 5 Morse taper. The spindle has a quick movement of about 6 in., actuated by rack and pinion. Its exact position is determined by a swinging stop at the rear, which drops over the end of the spindle when it has advanced far enough.

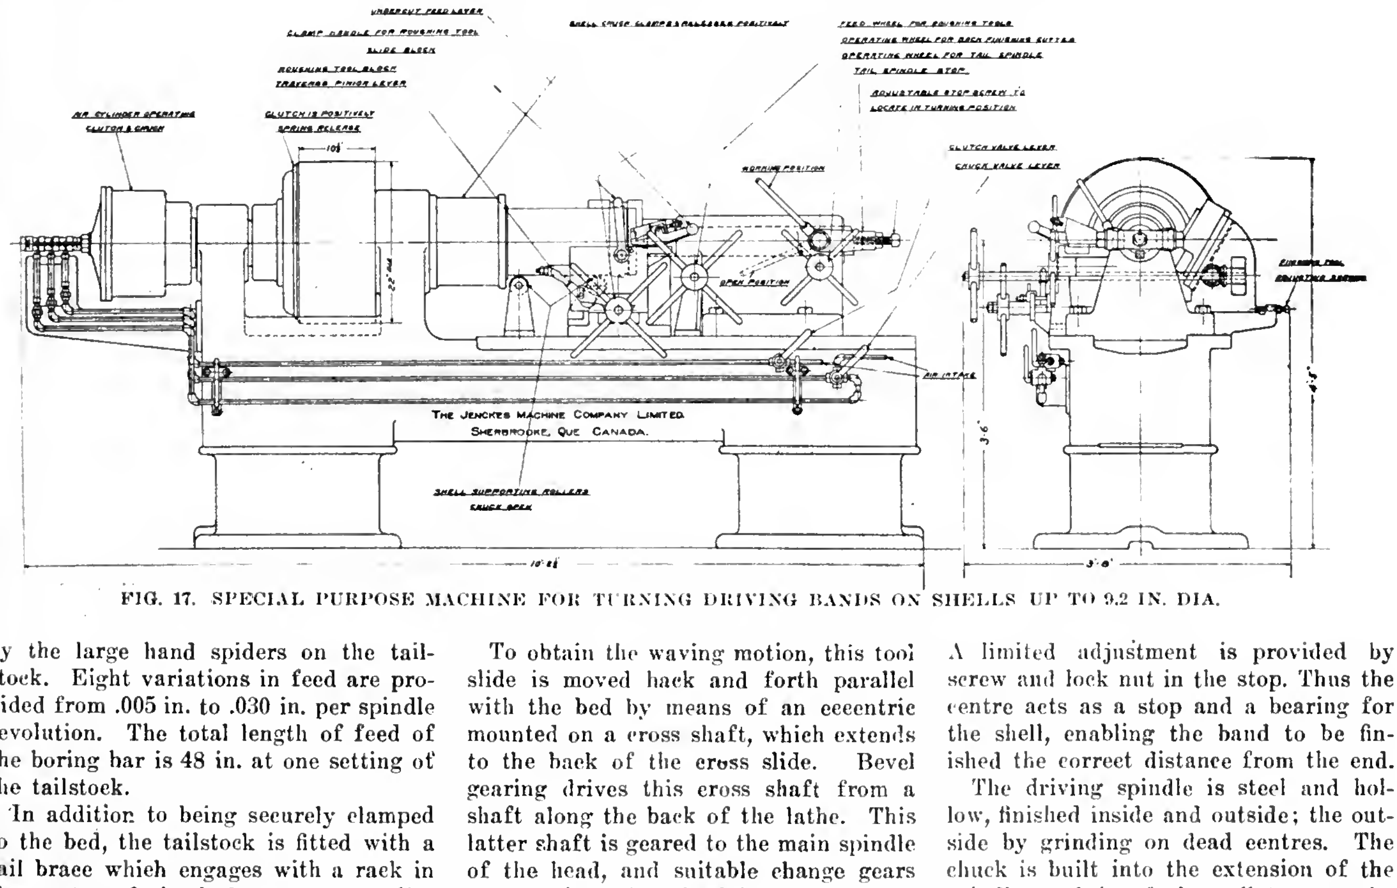

FIG. 17. SPECIAL PURPOSE MACHINE FOR TURNING DRIVING BANDS ON SHELLS UP TO 9.2 IN. DIA.

by the large hand spiders on the tailstock. Eight variations in feed are provided from .005 in. to .030 in. per spindle revolution. The total length of feed of the boring bar is 48 in. at one setting of the tailstock.

In addition to being securely clamped to the bed, the tailstock is fitted with a tail brace which engages with a rack in the centre of the bed, to prevent slipping under excessive thrust pressures.

The forward end of the bar is supported by an A-shaped bracket, which can be adjusted close to the mouth of the forging. This bracket aids greatly in eliminating vibration, and assists in the production of accurate work from irregular forgings. The steady rest is of stiff box section, with four rests, and has a capacity of from 6 in. to 20 in. in diameter.

When in use, this machine is fitted with boring heads of any desired style, the curved nose interior being formed

To obtain the waving motion, this tool slide is moved back and forth parallel with the bed by means of an eccentric mounted on a cross shaft, which extends to the back of the cross slide. Bevel gearing drives this cross shaft from a shaft along the back of the lathe. This latter shaft is geared to the main spindle of the head, and suitable change gears are provided for obtaining the number of waves required by the various shells.

While a machine of this type can be utilized for forming the bands, it is not always desirable to use a machine of such capacity on single operation work, except on the largest size shells. For use on shells from 8 in. to 12 in. dia. special band turning machines have been designed, one of which is shown in drawing, Fig. 17.

This machine has been placed on the market by the Jenckes Machine Company, of Sheerbrooke, Que., and is described as a single purpose air actuated

A limited adjustment is provided by screw and lock nut in the stop. Thus the centre acts as a stop and a bearing for the shell, enabling the band to be finished the correct distance from the end.

The driving spindle is steel and hollow, finished inside and outside; the outside by grinding on dead centres. The chuck is built into the extension of the spindle, and is of the collet type, the jaws being opened and closed positively by compressed air. It is operated by an air cylinder at the rear, the controlling valve of which is at the operator's right hand, below the tailstock. In closing the jaws, the shell is pushed forward until stopped by the tail centre. Jaw movement continues until the full pressure of the cylinder is exerted. The drive is through a single clutch pulley, 22 in. diameter, $10\frac{1}{2}$ in. face. The pulley is bronze bushed and runs loose on the spindle. The clutch is the full dia-

The Development of Quick Acting Forging Presses--I.

By A. J. Capron, M.Inst. C.E.

The accompanying article formed the subject matter of a paper presented at the International Engineering Congress, San Francisco, last September. Recent progress and present status of the art of forging, together with the relative advantages of the quick-acting forging press over the steam hammer, constitute the salient features of the detail contents.

DURING the past ten years great developments have taken place in the art of forging, and over widening fields of industries, requirements in forgings have increased rapidly. In the first place, large forgings are required, particularly for the increased calibre of guns that have been coming into use, and for turbine drums, wheels, and spindles, in many cases requiring an ingot of as much as 100 tons weight.

Again, forgings are being much more extensively used in preference to steel castings. This applies particularly to marine work, where reliability is the first consideration, and some saving in weight is of more consequence than economy in production. It also applies largely to forgings of all kinds for general engineering work. When steel castings were introduced, they were used in many cases to replace forgings, at first often made in iron and subsequently in steel, the steel castings effecting a great saving in the cost of machining, particularly in the case of articles of intricate form. The introduction of high-speed steel during the last fifteen years has so reduced the cost of machining that forgings have been replacing castings, in many cases advantageously as regards the cost of production, and their use in this direction is continually extending. This development is greatly assisted by the improvements that have been made in the art of forging.

For the production of the heavier forgings, presses have been used in preference to hammers for as long as thirty years in many of the large steel works; but such presses are comparatively slow in their action, and it is only within the last ten years that great improvements have been made in their design and construction, and more particularly in their speed of working, which has rendered presses suitable for almost all classes of work, except the lightest forgings, which come within the range of small steam hammers or drop-stamps.

Forging Press and Steam Hammer Comparison

The press possesses many advantages over the hammer in its effect on the material, in the manipulation of the forging, in output and economy in working, and in absence of noise and vibration, which, in the case of heavy hammers, is always objectionable, and often detrimental to adjacent buildings and machinery.

Effect on the Material

Dealing first with the effect on the material, the squeeze of the press penetrates to the centre of the forging, as is evidenced by the bulging of the sides of the forging at each stroke; whereas the blow of the hammer has much more of a surface effect, often leaving the sides of the forging quite concave unless the power of the hammer is very ample. As a result of this difference of action, the hammered forging shows a slightly finer texture on the surface, but a distinctly mor open grain of metal towards the centre. The pressed forging, on the other hand, shows a fairly fine and practically uniform texture throughout the entire section.

Individual tests may not always show a very marked difference between pressed and hammered forgings, because a good deal depends on the relative powers of press and hammer to the size of the forging, the temperature at which the work is done, and the subsequent annealing or heat treatment; but in the course of the regular manufacture of tires, for example, it has been found that much better and more reliable tests have been obtained from the press than from the hammer. This advantage of the press is recognized by Government requirements for forgings which stipulate that, for rolled or hammered steel, the ingot must have an initial section eight times the finished section, whereas those pressed need have an initial section of four times only.

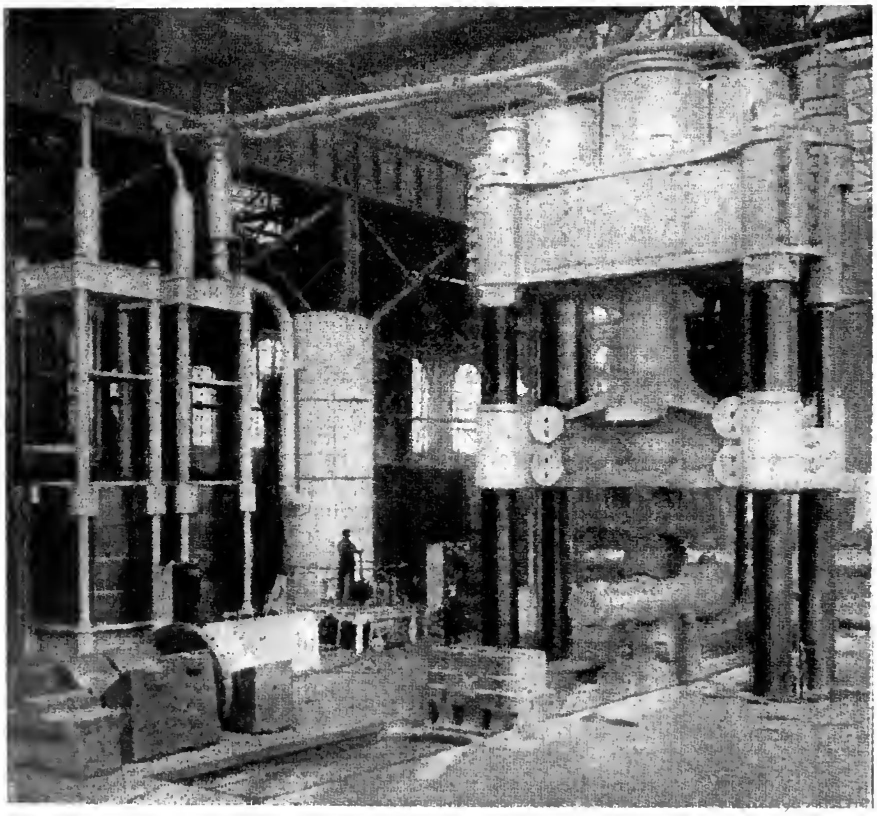

FIG. 1. MODERN FORGING PRESS OF 6,000 TONS CAPACITY.

Manipulation of the Forging

For the expeditious and accurate manufacture of forgings, a great deal depends on the ease and convenience with which the forging itself and the tools required for its production can be handled; and comparing the action of a press with the blow of a hammer, it will be readily understood that the advantage in these respects is entirely on the side of the press. In the first place, it is essential in working under a hammer that the forging should lie true on the anvil, otherwise a fair blow can-

not be struck, and an objectionable shock may be caused to the crane carrying the forging, and perhaps also to the men who are manipulating it; whereas a press will bring the forging to its correct position on the anvil without causing any jar and without interfering with the effect of the forging stroke.

When using tools under a hammer, much greater care must be used to place them correctly and to hold them in position, because the repeated blows of the hammer tend to displace them. A press on the other hand, once the tool is correctly placed, holds it in position until the cutting or forging stroke is completed. This enables such work as cutting or necking to be done much more easily and accurately under a press than under a hammer. For making a tapered forging with a press, a wedge-shaped block to give the correct taper can be laid on the anvil without any fixing. With a hammer, such an arrangement would require fixing to prevent its being displaced.

To forge accurately to size with large presses, a scale or indicator-dial can be used, worked from the cross-head, which enables the operator to read the reduction made at each stroke and to work the forging down to the finished size without any measuring. With small presses, a gauge piece is often used between the tool-faces which enables the forging to be made exact to size. With a hammer neither of these methods can be used conveniently.

Output

In almost all classes of work the press has a great advantage over the hammer in the matter of output. The blow of the hammer produces a very limited effect, generally reducing the forging by only the fraction of an inch, whereas the press will make a reduction of several inches per stroke, which, in straightforward cogging or rough forging work, naturally increases the output enormously. A good modern forging-press of 2000 tons will make as much as twenty 3-in. (75-mm.) strokes, or a total penetration or reduction of the forging of 60 in. (1,500 mm.) per minute. In rounding up or finishing a forging, such a press will work up to 60 strokes a minute, so that it is as fast as a hammer in finishing, and much superior to a hammer in cogging and rough forging.

As an instance of the output obtainable with a modern quick-acting press, a 2000-ton press of the steam intensifier type, starting with a 45-in. (1.143 m.) ingot, has cogged down and finished a 30-ft. (9-m.) length of well-finished 15-in. (381-mm.) shaft in one heat, using only flat tools. With a hammer of equivalent power, this work would have required not less than three heats. As another instance, a 1000-ton press, working on 24- in. (600-mm.) ingots, has forged 31 tons of 15-in. (375-mm.) round shafts in eight hours, and as much as 34 tons of miscellaneous forgings have been produced in eight hours by the same press. These are undoubtedly performances which could not be approached by any hammer.

With forgings of a more intricate shape, the advantages of a quick-acting press over a hammer are even more marked, because the same advantage in speed of penetration is obtained combined with much greater facility in handling the forging and, at the same time, the production of a forging more accurate to shape and size. As an instance, an 800-ton press, which is nominally equivalent to a 7-ton hammer, has produced the forgings for an anchor weighing 11 tons in three days. Properly, this size of work should have been done under a press of 1,200 tons, which could have cut the time occupied to about one-half.

Hollow forging is another class of work for which the press is much better adapted than the hammer. This is particularly the case in expanding operations for making hoops or drums, because the mandrel and its supports stand up far better against the squeeze of the press than against the blow of the hammer, resulting in more expeditious and better work.

Economy in Working

The principal factor in economy in working is the much larger amount of work that can be done in a heat under a good quick-acting press than under a hammer, as there is not only the actual saving in time, but considerably fewer heats are required to produce the same weight of forgings, and consequently the expenditure in fuel in reheating is greatly reduced. Besides this, the steam consumption of a good modern press is barely half that of a hammer for the same output.

Actual results over extended periods with presses have shown that in the production of solid, heavy forgings, such as shafts, the consumption of coal for steam production averages 3 cwt. (150 kg.) per ton of forgings; but for general work the consumption may be taken at from 3 cwt. to 5 cwt. (150 kg. to 250 kg.) per ton. It is evident that with a hammer a great deal of useful work is lost in vibrations; and in a paper on "Power Forging," with special reference to forging-presses, by Gerdau and Mesta, published in the Journal of the American Engineer, July, 1911, it is assumed that this loss amounts to one-third of the useful work, which is probably not over the mark. A calculation by the same authors gives the following results for equivalent powers of hammer and press:

Steam hammer, per stroke, 8 lb. (3.73 kg.) steam.

Steam, hydraulic press, per stroke, 3.7 lb. (1.68 kg.) steam.

An exact comparision is difficult to obtain; but the statement made above—that the steam consumption of a good modern press is barely half that of a hammer under average working conditions—is probably well within the mark.

When coal-fired furnaces are used for heating the forgings, it is often possible by means of the waste heat from the furnaces to raise sufficient steam for working the press. This is generally more convenient and economical than using gas-fired heating furnaces and independently-fired boilers.

Absence of Noise and Vibration

The press, with its silent working and absence of vibration, contrasts very favorably with the hammer, which causes much inconvenience and often considerable detriment to adjacent furnaces and buildings and to the working of any machine-tools in its vicinity. In many cases the inconvenience caused by hammers to adjacent establishments has been so great that, on this account, it has been necessary to replace them by presses. Besides this, the foundation required for the press is very small and inexpensive compared with what is required for a hammer; and when the nature of the soil is unfavorable, this difference is accentuated. The working of the press is also much less detrimental to the tools which can often be of cheaper construction and require less frequent renewals.

Capacity of Press and Equivalent Power of Hammer

The following table, which gives the maximum diameter of ingot that each power of press is capable of dealing with effectively and the equivalent power of steam-hammer, will be of assistance in making a comparison of the two methods of forging:—

Ingot Diameter In.	Ingot Diameter mm.	Press Power tons	Hammer Power tons
5	123	100	0.50
6	150	150	0.75
8	200	200	1.00
10	250	300	2.00
12	300	400	3.00
14	350	500	4.00
16	400	600	5.00
20	500	800	7.00
24	600	1000	10.00
30	750	1200	15.00
36	900	1500	20.00
48	1200	2000	40.00
60	1500	3000	80.00
72	1800	4000	120.00
84	2100	5000	—
96	2400	6000	—

From this table it will be seen that the power of the press bears a fairly direct proportion to the diameter of the ingot, but the power of the hammer required increases much more rapidly, being nearly proportional to the square of the diameter or the sectional area of the in-

got. For instance, for an ingot 24 in. (600 mm.) in diameter, the power of press is 1,000 tons, and the hammer 10 tons; but for a 48-in (1,200 mm.) ingot, the power of press is 2,000 tons, and the corresponding hammer 40 tons, and. consequently, the heavier the work the greater is the advantage of the press over the hammer.

As stated above, for the heavier classes of work, presses have been used in many of the principal steel works for as long as thirty years, the power of such presses most generally used, up to twenty years ago, being from 2,000 to 3,000 tons, though during this period some much more powerful presses, up to 10,000 tons, have been put down for forging armor plates and for special purposes. During the next ten years—that is, up to ten years ago—owing to the increased size of guns and other forgings required, a good many presses of 4,000 tons have been adopted.

During the last ten years—that is up to the present date—owing to the further increase in the size of guns, and also to the larger forgings required for marine work, particularly turbine-drums and spindles, the power of press required has increased correspondingly, 6,000 tons being the power most recently adopted for the heaviest work of this class.

Method of Driving Press

To explain the development in the use of the press, some mention must be made of the improvements that have been introduced in the method of driving. The earlier forging-presses have generally been driven by means of pumping-engines working direct into the press cylinders, the working pressure being usually from 2½ to 3 tons per sq. in. (400 km. to 480 km. per sq. cm.). For large presses this method gives satisfactory results, but it has never been used to any extent for presses of medium or small power, for which greater simplicity and a higher speed of working, especially in finishing, are more essential.

Another method is to make the press purely hydraulic, working it from an accumulator. For certain special work, such as piercing projectiles or billets for tube-making, in which a long stroke without any pause is desirable, this system is undoubtedly the best. For ordinary forging operations, however, for which a short, rapid stroke is essential, this system has only been adopted to a limited extent and is applicable only to presses of comparatively small power.

The system that fulfils the requirements of forging best is the steam, hydraulic intensifier. For a good many years it has been used to some extent, but it is only within the last ten years that it has come into general use and been adopted extensively for presses of small and medium power as well as for the heaviest forging-presses. The advantages of the steam-intensifier presses are that, in its latest and best form, it is capable of fulfilling adequately all the requirements of forging.

These include sufficient rapidity of action in all its movements—that is, the idle stroke when lifting the press-head and bringing it down to its work and the forging stroke or penetration. The idle stroke should be from 6 in. to 12 in. (152 mm. to 305 mm.) a second, according to the power of the press and the nature of the work, and the forging stroke up to 3 in. (76 mm.) per second, according to the resistance of the forging. Also there should be no pause or dwell either when the tool first touches the work—that is, before the forging stroke commences— or at the end of the forging stroke; that is to say, the return stroke should commence directly the penetration is completed, any pause causing loss of time as well as chilling the forging. The length of the forging stroke is usually from 1 in. (25 mm.) up to 6 in. (150 mm.), or 8 in. (200 mm.) in the case of very large presses and the speed of such forging from 10 up to 50 strokes a minute, a total penetration of 60 in. (1,500 mm.) a minute being obtainable when the power of the press is well up to its work and the forging handled expeditiously.

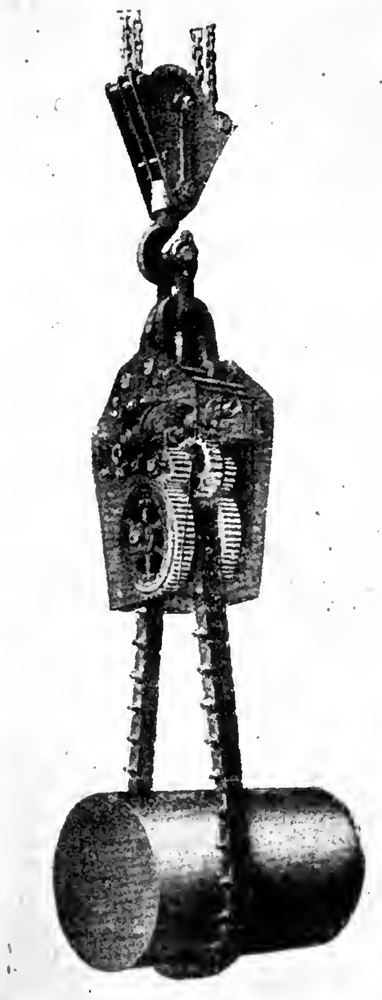

FIG. 2. ELECTRICALLY-DRIVEN TURNING GEAR FOR ROTATING FORGINGS.

For rounding or finishing a forging, a very rapid stroke is desirable; a good intensifier press of as much as 6,000 tons being capable of working up to 40 strokes a minute, and smaller presses proportionately quicker up to 100 strokes a minute. With these speeds of working an efficient control-gear is desirable both to limit the forging stroke and also to prevent any overrunning of the intensifier in case the load on the press is suddenly removed, owing to the forging or tool slipping or other accidental cause. So successfully has efficient control-gear been applied to intensifier presses that they can be worked quite safely and easily at the high speeds mentioned. Presses already constructed on this system range from 100 up to 6,000 tons power, the larger presses giving proportionally equally as good results both in forging and in rapid finishing strokes.

Forging Operations

Fig. 1 illustrates an up-to-date forging-press of 6,000 tons power, engaged in forging a solid shaft. This press is driven by two intensifiers, arranged to work simultaneously or independently by means of catches on the handing-lever. Working simultaneously, the intensifiers give a forging stroke of 10 in. (250 mm.) and a speed of from six to ten strokes a minute, according to the penetration required. When short strokes for finishing are required, either intensifier can be used and the press can be worked up to forty strokes per minute.

The full equipment for such a press, to enable it to deal advantageously with the various classes of work, includes the following:—

Mandrel-gear, giving the mandrel-blocks a travel of about 30 ft. (9 m.) on each side of the press.

An extended base of sufficient strength so that the full power of the press can be exerted on the mandrel-blocks when they are spaced at the maximum distance apart required for expanding work, such as turbine-drums or gun-jackets.

Manipulating gear for handling forgings without the use of a crane:—this is particularly useful for certain classes of work, such as forging armor-plate and turbine-wheels, and also in some cases for cogging ingots.

Transverse tool-changing gear:—this is useful for forging crank shafts and similar work when it is desirable to change from flat tools to V-shaped or swaging tools. The gear enables both top and bottom tools to be changed very

quickly without taking the forging from under the press.

Turning-gear for rotating the forging:—The most convenient form is a self-contained electrically-driven gear, suspended from the crane-hook. Fig. 2 illustrates such a gear. Preferably this should be provided with a friction-clutch which slips during the instant that the press grips the forging.

A press with the above equipment is suitable for practically all classes of heavy work. Examples of forgings made under such a press will be given in the continuation of the present article next week.

OPEN-HEARTH VS. ELECTRIC FURNACE FOR COMMERCIAL STEELS

THE fundamental question is one of cost, and any authentic figures are always welcomed as throwing fresh light on this subject, which is of great commercial interest. The fact that the electric furnace can successfully compete with the crucible process, and in some cases with the small converter, is, we think, established, but a comparison of the electric furnace with modern open-hearth furnace is open to discussion, and is made the subject of an article by S. Cornell in a recent issue of the Metallurgical and Chemical Engineering.

In order to provide data on this point a table has been compiled for a year's operation of a large open-hearth plant and compared with what is claimed to be practice obtainable in an electric furnace plant of the same capacity. The open-hearth plant consisted of 80-ton furnaces, having a production of 200 tons of ingots per day for each furnace, compared with 20-ton electric furnaces, approximately the same capacity per day.

Dealing with the materials necessary to make one ton of steel, and including all consumable material and cost of repairs, it is calculated that the cost per ton of steel is $14.50 for the open-hearth against $18 for the electric steel. The cost and quantity of raw material is taken to be the same in both cases, and the difference is due entirely to a fuel cost for producer gas being 54 cents for the open-hearth, as against $4.40 for electric power in the electric furnace.

The general labor charges which are common to both processes is worked out at $1 per ton of steel, whilst the cost of general repairs is given as 6 cents per ton.

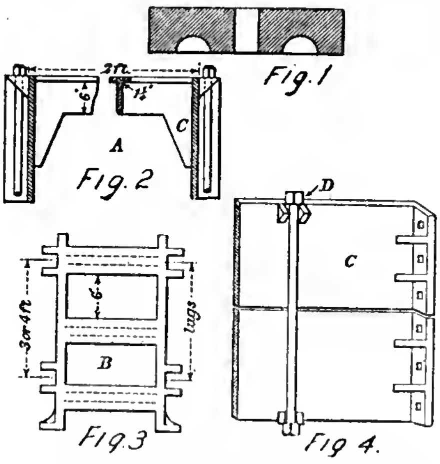
From a careful consideration of the outlay necessary in installing electric furnaces of sufficient capacity to produce the same tonnage as a set of open-hearth furnaces, it is calculated that in order to compete in cost the electrical energy must be produced at below 1 cent per kilowatt-hour.

The present electrical equipment using blast furnace gas cannot do better than 7 cents per kilowatt-hour.

HINTS TO FOUNDRYMEN

A CONTRIBUTOR to "Engineering" says it appears to be general practice to make patterns for all classes of castings, light or heavy, and to ignore loam work as being either too costly or causing too much dirt in the shops. This is entirely wrong, as I think some of those in charge have but little knowledge of how loam work can be made to advantage over sand, both as regards cost and keeping the shop just as clean.

I was talking to a gentleman the other day, who thought that his was quite a modern concern. They were engaged on one class of engine, etc., or what might be called repetition work. There was one casting in particular being made from patterns; this was what molders commonly call a block fly-wheel,



ILLUSTRATING HINTS TO FOUNDRYMEN.

up to 12 ft. in diameter, as shown in sketch (Fig. 1). Now to make such castings as these in sand is not only increasing the cost, but causing a lot of unnecessary hand labor for the molders.

Anyone that claims to know anything of modern foundry practice could take 10 per cent. from the cost of a casting of this kind by making it in loam, and more than another 10 per cent. from all others that were required. There is plenty of room yet for green, dry sand and loam work in a modern foundry, and castings can only be produced economically by sound judgment in the use of them.

Jobbing Foundry-Box Parts

The writer has worked in plenty of jobbing foundries doing a fairly decent class of work that could be cast on its joint, but if anything came along that had to be cast vertical, it had to be rejected as being something out of their particular line. Now if the boxes had been made to tackle any class of work, such castings as hydraulic bodies, rams, etc., could have been made.

All that is required is a crane of sufficient height to turn them up, to make the bars in the box with lips as shown in the sketch (Fig. 2) like a T, and to place lugs (Fig. 3) at the back about 3 ft. or 4 ft. apart, for the boxes to be bolted with these when they are being used vertically. A cross-section of the box is shown at A; the top and distance of the bars should be apart are indicated at B, while C shows a side view of a pair of boxes, and D the bolts and method of fastening. These can be made in lengths to the requirements of the foundry; 6 ft. and 9 ft. are fairly handy. The boxes can be bolted at the ends to make any length required; they are perfectly safe, no plating or the back of the bars or ramming being required.

Splitting Castings

The best method of treating splitting plates for castings is to glue a thin layer of asbestos over them; when cast they will rap out, leaving a smooth, clean face.

LARGE SHELLS: PRODUCTION PROBLEMS AND POSSIBILITIES.—V.

(Continued from page 545.)

meter of the inside of the pulley, and is of the taper cork insert type. It is operated by a separate valve and the release is by springs. The thrust of the spindle is taken at the forward end bearing, a take-up collar being provided at the rear of the same bearing.

The tool base is bolted firmly to the bed and carries both roughing and finishing heads. On the 9.2 in. the roughing is split into two operations. Each tool is fully adjustable, but when once set, they can be removed and replaced with precision. The feed of both tools is by a single screw to positive stops. The undercutting tool is on a separate block mounted on the front slide at the correct angle and is fully adjustable. The feed is through lever and cam. The rear or finishing tool is so mounted that the tool slides past the band and shears it to the exact size and shape. The tool block is securely bolted to the base, but is slightly adjustable to and from the cut. It can also be rotated if necessary, so the tool will cut both ends of the band to correct size. The feed is by rack and pinion, with handle in a convenient position for the operator.

Two roller supports are provided on the bed so that the shell can be lowered by an air hoist or other means into the chuck, and in line with the centre. The rollers are not in contact with the shell when it is rotating.

GALVANIZING CONDUITS

THE manufacture of galvanized conduits at the plant of the Orpen Conduit Co., Toronto, Ont., presents several interesting features, the principal one being that the pipe is copper-plated before being galvanized. Copper-plating is a protective covering of great value in resisting corrosion, forming an ideal "couple" between the metal of the tube and the zinc. The zinc is, therefore, deposited on copper and not on iron by means of the electro-deposition process, thus its full value as a rust preventative is secured.

This conduit, which bears the trade name of "Xceladuct," is a high-grade mild steel butt-weld pipe of special quality, being heavier than ordinary tubing. The pipe for the straight conduit is received at the factory in 10-ft. lengths, and is made in Canada; the bends are, of course, shorter. The pipe is threaded at both ends, one end having a coupling when shipped. The conduit is made in sizes from ½ in. to 6 in. inclusive.

Pickling Process

The first process consists of pickling, which is done to remove the scale, etc., from the pipe. For this process there are installed a number of wood tanks, the first containing a potash solution for removing oil or grease from the pipe. The pipes are then dipped in a tank containing sulphuric acid, which removes the scale. They are then dipped in another tank containing muriatic acid, which gives a smooth surface to the pipe.

On the completion of the foregoing, the pipes are laid out on a flat table, where they are carefully inspected. A powerful light at one end enables an examination of the inside to be made. Any defective pipes are laid to one side, and the sound ones are taken over to the plating department.

Plating and Galvanizing

In the plating department are installed a series of five tanks in one row, each being 14 feet deep, and having a capacity of 4,000 gallons. The tanks sit in an asphalt pit, and are constructed of wood or steel, according to the character of solution which they contain. Before being dipped in the first tank, the pipes are assembled in a "basket," in which they are held until this process is completed. The basket is made of copper, and is constructed so as to hold the pipes vertically. It has a capacity for 175 lengths, each 10 ft. long, of ½-in. pipe, equivalent to 1,750 ft. The larger sizes, being heavier, fewer pipes are dipped at one operation.

The basket is suspended from and carried along by means of an electrically-operated hoist on an overhead runway, extending the full length of the tank. At the end of the operation, when empty, the baskets are returned on an overhead runway at each side of the tank. The hoist has lifting and lowering motions for use when dipping the pipes.

The pipes are dipped in three different solutions before being copper-plated. After being in the copper-plating tank the prescribed length of time, they are taken out and dipped in the zinc tank, where they remain about 45 minutes. They are then taken out and put in the rinsing tank.

The electrical equipment for the zinc and copper tanks consists of two motor-driven plating dynamos. One unit consists of a Canadian Hanson & Van Winkle Co. plating dynamo, 8,000 amperes, 6 volts., direct-connected to an 85 h.p. C.G.E. motor running at 470 r.p.m. The other unit is of the same make and size, but belt-driven by an 80 h.p. C.G.E. motor. The wiring from the dynamo is taken under the floor, up the outside of the tank, and connected to the anodes.

Drying and Insulating

After the pipes have been rinsed, they are taken from the basket and placed vertically over a grating through which air is passing from a blower. The pipes are thus thoroughly dried before being insulated and again inspected. For the insulating or enameling process, the pipes are laid inclined on a table and the enamel flows from an overhead tank through them into a shallow tank, whence it is pumped back by means of a motor-driven rotary pump to the overhead tank. The pipes are then placed vertically over a grating to dry, a current of air passing through accomplishes this.

They next go to the labeling table, where they are laid flat and two labels affixed—one factory label and one for the Underwriters. At this stage the pipes are carefully examined by the Underwriters' inspector, who selects one from each batch to be tested. Before leaving the table, a coupling is screwed on one end of each pipe, after which they are tied in bundles ready for shipping. The test pipe is cut in two sections on a hack saw machine, and a length taken to the inspector's office, where it is tested to ascertain if the zinc coating and enamel are adhering in a satisfactory manner. The tests are very thorough, as the conduit must conform in all respects to Underwriters' rules.

Elbows

The above-mentioned processes cover the straight lengths of conduit only. The elbows are treated in a somewhat indifferent way, chiefly as regards handling. Short lengths of pipe are received at the factory, threaded at both ends. The first requirement is to bend them to the required angle and radius. For the larger pipes a belt-driven bending machine operated from the line shaft is used, while the smaller size pipes are bent in a steam-operated machine. In both cases different forms are used to suit the various sizes of pipe.

The elbows, as in the case of the straight pipes, undergo the pickling process and in the same set of tanks. The elbows are, however, scrubbed with sand after being pickled. They are then copper-plated in the same tank as the straight lengths, but have a separate tank for the galvanizing process. The current for the zinc tank is furnished by a plating dynamo, which is also connected to the zinc tumbling tank used for galvanizing the couplings. The dynamo supplies current at 6 volts, 400 amperes. After being galvanized, which takes about 30 minutes, the elbows are taken out and hung on a rack to dry, and then taken over to the insulating tank to be enameled inside. After being enameled, they are hung on racks to dry, and are then inspected and stamped the same as the straight conduit. The elbows are also inspected and tested between the various processes. All sizes are treated in the same way.

Couplings

As already stated, a coupling is supplied with each length of conduit. The first process consists of pickling, which is done in the same set of tanks as the pipe and elbows. They are also copper-plated in the same tank, and are held in wire baskets during the process. For galvanizing, there is a special tumbling tank installed, in which the couplings are revolved for three hours. When the galvanizing process is completed, the couplings are taken out and washed in cold water. They are then put in wire baskets, washed again in hot water, and afterwards laid on a wire screen to dry. They are afterwards taken to the store room to be used as required.

CHUCKS VERSUS FIXTURES

By D. A. Hampson.

ALMOST every part that is made in quantities of one hundred or more requires some sort of fixtures if the work is to be done cheaply and the parts have to be at all interchangeable. The commercial side should determine how elaborate these fixtures are to be; but before going to the expense of making or even of designing them, it is well to take account of stock and see if there are no standard adjustable fixtures which can be used instead.

Into this class come chucks,

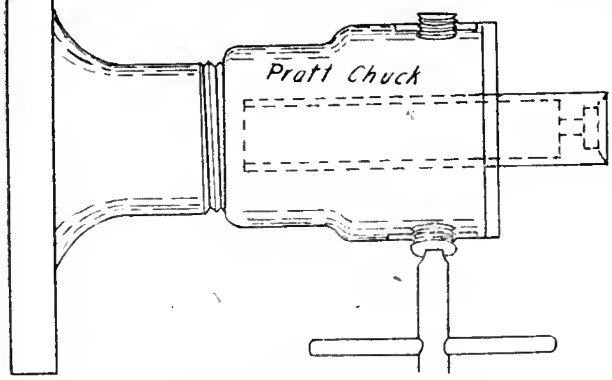

FIG. I. CHUCKS vs. FIXTURES.

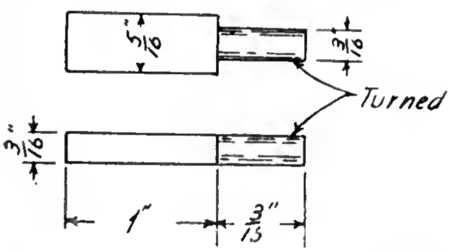
drill heads, jigs, vises, etc. On work that is to last but a few days or a few weeks, such tools can be made to show almost as great a production as specially made-up tools, and show a nice saving in initial expense and ultimate discarding. Two cases in which ordinary drill chucks were used to advantage will be reviewed.

Ten thousand brass shells were to have an 1/8-inch hole drilled through the end. Instead of making a special holder for these, a Pratt drill chuck of the familiar two-jawed type was selected from among the "spares" and a cast iron base made to support it. The drawing shows this and also the wrench for opening and closing, the wrench being made a tight fit in the socket, so it is always in place. A quicker or more satisfactory



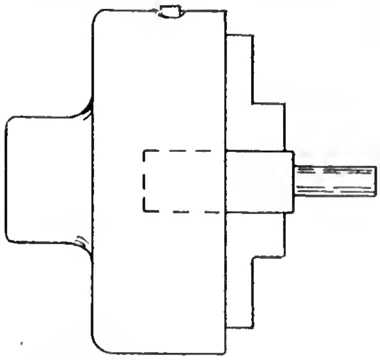


FIG. 2. CHUCKS vs. FIXTURES.

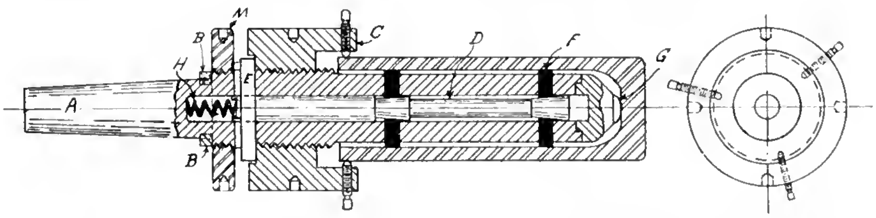
fixture would have been impossible to make, and when the job was done we had not added as much as a dollar to the obsolete tool account.

A "trial lot" of a new mechanics' tool required a thousand pieces of 3-16 x 5-16 drawn steel, with a symmetrically turned stem at one end. There was in the tool room a nearly new two-inch, two-jawed Cushman drill chuck. To this we fitted a shank that was fitted to the "centre" taper of a lathe spindle. The jaws of the chuck being V-shaped, formed a perfect driving and centering medium. After milling the pieces to length, they were turned in the chuck, suitable stops having been arranged for position, length and diameter. It is doubtful if any special fixture would have done the work more accurately—it is certain that they would not have paid on a quantity of this size.

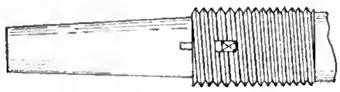
EXPANDING MANDREL

By G. Barrett

THE expanding mandrel is undoubtedly one of the most called-for tools required in the manufacture of shells, and its use has never been so widespread as it is at the present time. The one which we illustrate herewith was designed for a lathe which had been temporarily out of commission owing to the lack of a hollow spindle.



AN EXPANDING MANDREL.



The end of the mandrel A is fitted to the tapered hole in the lathe spindle and is prevented from turning by means of the pins B which engage with two corresponding slots in the spindle nose.

In operation the shell is first placed over the mandrel till it touches the point G. The nut C is then tightened against the cotter F, causing it to draw up the rod D, the inner end of which projects into the hole H. By this means the tapered diameters on the rod D force the dogs F outward against the shell. By tightening the three set-screws shown in the nut, a firm grip is assured, since the strain of the cut will have the tendency to still further tighten the nut.

To remove the shell the set-screws are slackened off and the nut C is screwed back. A slight pressure is then applied to the cotter E by means of the nut M. This forces the rod back and relieves the strain on the dogs sufficiently to allow the spring H to force the rod back the remaining distance and thus release the shell.

TRADE WITH BRITAIN

AN increase in Canadian trade with Great Britain, particularly in exports, is shown in British trade returns for the nine months of the present fiscal year ending October 31st last, which have reached the Trade and Commerce Department. The 1915 figures of Canadian trade for this three-quarter period were $188,824,340, as compared with $174,000,000 in 1914. Of the former total, over $138,500,000 was in Canadian exports. Canada's trade was considerably less than Australia's, which totalled $300,000,000, probably due to the purchase of war munitions. Great Britain's trade with the United States increased by about $350,000,000. The October figures also show a decrease in the disproportion evident between British imports and exports since the war. From this, the inference is drawn that the English people are beginning to economize by cutting down consumption of all but necessities.

Truing an Oilstone.—To true an oilstone, the Mechanical World suggests the following method:—Take a piece of soft pine board of any thickness, about 8 in. wide and 3 ft. or 4 ft. long. Lay it on a bench and fasten it with a handscrew or other clamp. Put on some clean, sharp sand, screened about as fine as that used for plaster work. Use no water, and rub the stone back and forth over the board in sand. This will give a flat surface to the stone in a short time. Care should be taken to move the stone on straight lines, so as not to give it a warped surface. If a fine surface is wanted, a finer grade of sand or sandpaper may be used to finish with.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

GRINDING ENDS OF SHELLS

AT the square end of a shrapnel shell there is a small turning hub or centre projection which has to be removed before the shell is completed. There are various ways of removing this stock, but production is the essential factor in all. The Gardner Machine Co., Beloit, Wis., has developed a special grinding machine for this operation,

This equipment is also used for cutting off the square or angular hubs from base plates in high explosive shells as well as on shrapnel casings. From a grinding standpoint, the operation is the same in both cases. In some instances the hub is removed by some other process and the riveting done. It is then placed on the grinder and the balance of the base plate is removed, taking a light cut over the entire base of the shell as well.

The machine consists in the main of a very heavy base casting, with a 2-in. diameter spindle, mounted in either high-grade babbitt bearings or ball bearings. On each end of the spindle is mounted a "Perfection" ring wheel chuck, of improved design. These chucks contain 16-in. diameter abrasive rings selected for these operations.

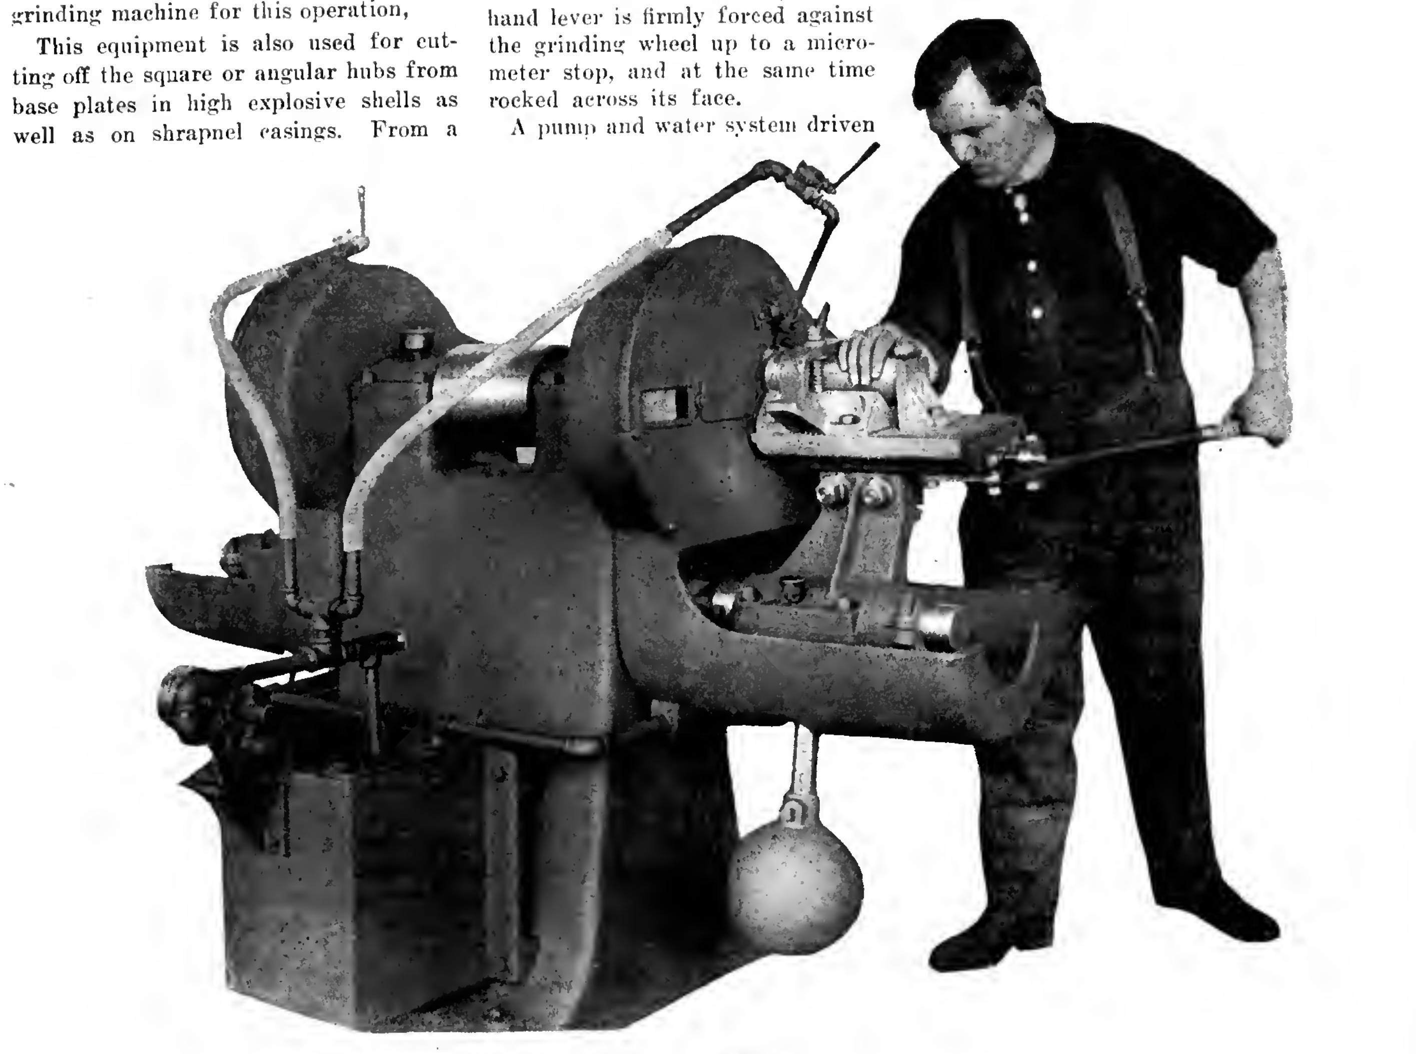
Lever feed work tables, supported on a rigid rocker-shaft running entirely through the base, serve the grinding wheels. The shell is quickly clamped into "V" fixture, and by means of a hand lever is firmly forced against the grinding wheel up to a micrometer stop, and at the same time rocked across its face.

A pump and water system driven from the counter-shaft directs the water or grinding compound at the point of grinding contact. The hoods and basin are one-piece castings.

The output obtained from one end of the machine varies according to the size of the projection to be removed, being from 40 to 100 per hour. This machine, with both ends equipped and operated by two men, gives double this output.

The complete equipment includes two 16 in. "Perfection" chucks, two 16 in. abrasive ring wheels, two semi-universal lever feed work tables, two shell-holding fixtures, water pump, with connections, countershaft and general supplies. The whole outfit weighs 4,000 pounds.

This firm also builds a No. 50 grinder, which is much heavier and more powerful than the one illustrated herewith, and which is also being adopted by manufacturers of 6-in. shells for these same operations.



MACHINE FOR GRINDING BASES OF SHRAPNEL SHELLS.

DIAL FEED ATTACHMENT FOR LARGE SHELLS

THE Ferracute Machine Co. of Bridgeton, N.J., has recently developed an automatic dial feed attachment for use in cupping and re-drawing cartridge cases and other sheet-metal shells, the attachment being used in connection with straight-sided presses exerting pressures from 100 to 200 tons.

The illustration shows a 100-ton press fitted with one of these attachments, the dial having six recesses, it being essen-

tial that a recesss be in alignment with the centre of ram as it descends to insure the entrance of the punch in the partially drawn shell. Pressure on the treadle will cause the press to stop instantly at any portion of its stroke.

The dial has an intermittent motion, being at rest while the press makes a stroke. A cam on the main shaft gives motion to the rack that partially revolves the dial yoke. An additional cam on the main shaft operates the "lock" mechanism. This lock is a lever containing a wedge-shaped end that fits each of the six notches in the circumference of the dial.

Connected to the lock mechanism is an "interrupter." When the lock is in a notch, indicating that the ram and dial-recess are properly aligned, the interrupter prevents a weighted rod from descending, but if by any mischance the lock should fail to enter its notch, the interrupter will change its position, allowing the weighted rod to descend and depress the treadle, causing the press to instantly stop, and thereby avert damage. After cause of trouble has been ascertained and adjustment of dial finished, the press may be made to complete its stroke by pulling down the handle-strap, the ascending ram elevating the weighted rod, and the treadle and treadle-rod assuming their first position.

The press is equipped with a combined friction clutch and brake. Pulling down the hand-lever connects the power to the shaft, giving motion to the press, while depressing the treadle releases the clutch and applies the brake. The machine is, therefore, under perfect control at any position of its stroke.

There are several adjustments that give accuracy to the motion of the dial. For instance, the amount of rotation of the dial may be regulated by means of a roller at top of yoke, set-screws being provided to give exact position. The motion is also controlled by a brake which is automatically released during the locking process. There is an eccentric adjustment which provides for the accurate relation between the lock and its notch, the tension of the lock being regulated by means of an adjusting spring.

Although designed primarily for continuous action, the press with its attachment can be used intermittently, that is, automatically stopping at the end of each stroke. When running continuously, 12 shells per minute are produced.

1,000-TON HYDRAULIC CARTRIDGE CASE HEADING PRESS

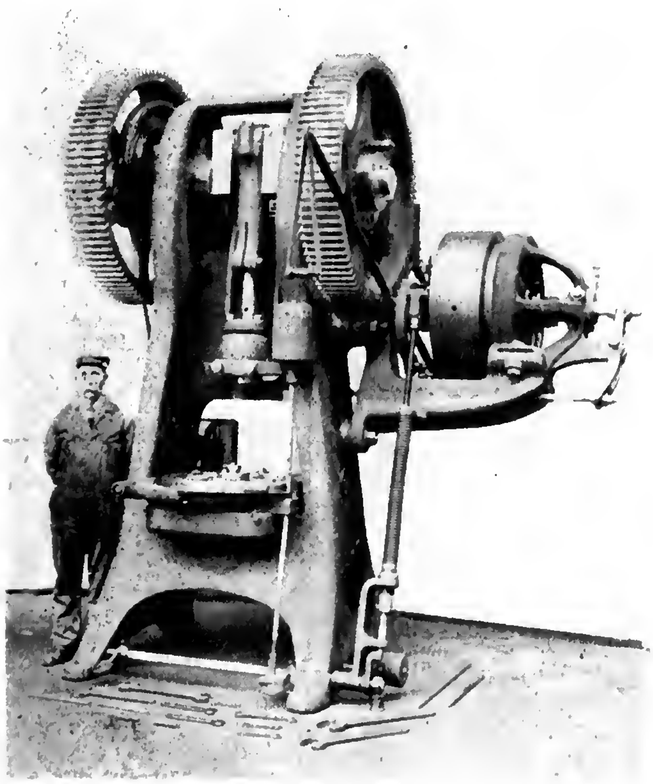
THE hydraulic press, illustrated, was designed for the heading of brass shells after they have been indented. The heading operation is accomplished by inserting a fullering block between the head of the press and the top of the cartridge case, the latter being held in place by a suitable die. As the pressure is applied, the fullering block causes the brass to flow outward in all directions, thus forming the head of the shell.

The press has a revolving turret with dies to receive three shells. This provides for an almost continuous operation, as there is always one shell awaiting the heading operation and one shell being unloaded, while the other shell is undergoing the heading operation. The rotation of this turret is controlled by an indexing device, so that the shell is accurately held in place directly beneath the fullering block.

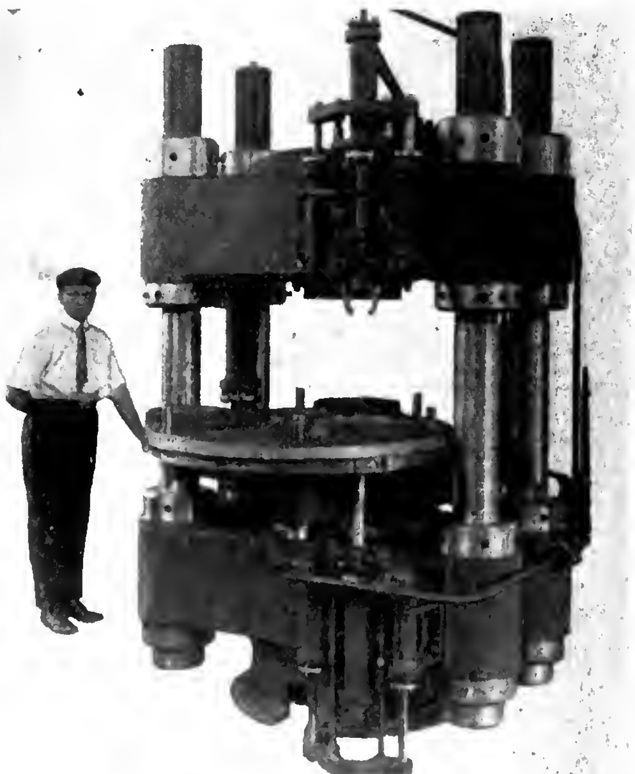
The indexing device is operated by a lever conveniently placed for the operator. By merely pulling the lever, the index latch is disengaged from the turret, clearing and releasing the turret for revolving. The photograph shows a rear view of the press. The lever controlling the indexing device is shown to the extreme right. The operating valve is entirely hidden by the press.

The turret revolves on a spindle mounted in ball bearings, which are set in the front side of the press between the strain rods. Handles placed around its outer edge at an equal distance apart are fitted for the purpose.

After the heading operation is completed, the shell is pulled from the die by an hydraulic ejecting device, which consists of two rams, one attached to the head of the press and the other to the base. Spring gripper jaws are attached to the upper ram for gripping the head of the shell. Each of these rams is provided with two auxiliary pull-back rams.



DIAL FEED ATTACHMENT FOR CUPPING AND RE-DRAWING CARTRIDGE CASES.



1,000-TON HYDRAULIC CARTRIDGE CASE HEADING PRESS.

The ram attached to the base of the press forces the shell up out of the die to a point where the gripper jaws on the upper ram can readily take hold of the newly-formed head. Pressure is then applied on the auxiliary rams for the return of the ejector rams. The finished shell is next removed from the gripper jaws of the upper ram and the device is ready for the next shell.

The use of two ejector rams, each working toward a common centre, makes the ejecting operation much more rapid and clears the turret in less time, so that it can be revolved more quickly for heading the next shell. The maximum pressure of the two ejector rams is 5 tons each.

The press is of steel construction throughout, the base and cylinder being cast in one piece. The ram has a diameter of 28 inches and a run of 12 inches. The press has an adjustable daylight of 30 to 45 inches.

The maximum total pressure capacity of the press is 1,000 tons, and the number of pressings per minute depends upon the capacity of the pump used for its operation. As a basis, the press will make 3½ pressings per minute with the pump furnishing 19¼ gallons of water per minute at a pressure of 3,250 pounds per square inch.

This projectile press is a new design and recent addition to those being built by the Hydraulic Press Mfg. Co., Mount Gilead, Ohio.

DOMINION ECONOMIC COMMISSION

AS a first step of the recently-appointed Federal Economic Commission, under Hon. J. A. Lougheed, towards securing working data from which to draw conclusions, a special census of Canadian industrial companies is to be taken. At the conclusion of the meeting held on Dec. 13 of the commission, R. H. Coates, Director of the Census and Statistics Branch, announced that a census of manufacturers would be taken by post next month. All manufacturers will be asked to fill out a census form, giving details as to capital invested, number of employees, wages, etc., and volume of production, distinguishing between war orders and general business.

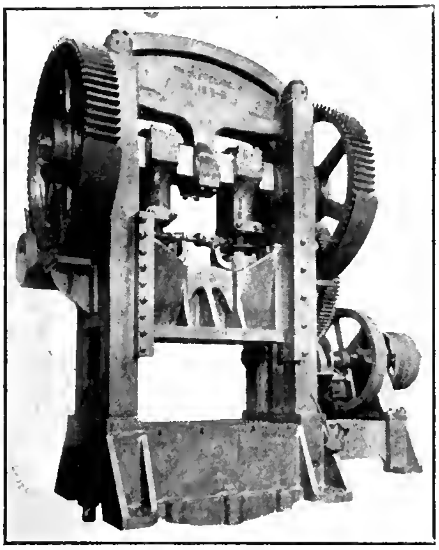
Efforts also will be made by the Commission to get the latest comprehensive and reliable information regarding agricultural production, including cost of production, market facilities, etc. In this connection the various agricultural associations will be asked to co-operate.

After the preliminary information sought is received, the Commission will visit various centres in sections and take public evidence as to needs, and recommendations looking to a better conservation of the national resources, and more economic methods of marketing, etc.

HIGH-DUTY POWER PRESS

FORCED production of automobile parts is creating a demand for stronger and heavier presses, with greatly increased factors of safety. The machine illustrated was recently developed by the Cleveland Machine & Mfg. Co., Cleveland, Ohio, for the production of automobile frame cross-bars and similar heavy forming, blanking and drawing.

A heavy spring drawing attachment (not shown) is mounted in bed of press, and is used for operating knock-out pads



HIGH DUTY POWER PRESS.

and drawing or pressure rings. The gearing is of steel throughout, with machine-cut teeth. The friction clutch is multiple disc type and very powerful.

The principal dimensions of the machine are as follows: Gross weight, 167,000 pounds; bed area, 72 in. R to L, x 48 in. F to B.; crank shaft, 10 in. diameter in bearings and 11¼ in. on crank pins; stroke of slide, 10 in.; distance bed to slide, stroke down and adjustment up, 26 in.; proportion of gearing, 45:1.

QUICK-FIRING GUNS

THE rapid development of artillery during the last few years has naturally led to the coining of a number of phrases to express the difference between the various types, and distinguish the new from the old and obsolete; while the rapid education of the general public in the elementary principles of modern warfare has brought some of these phrases into common use. It not infrequently happens that a whole series of remarkable improvements are designated for general use by a single expression. An excellent example of this is the term "quick-firing" as applied to modern gunnery.

Less than twenty years ago, it was recognized that the gradual development of the field gun had made so many changes necessary in the tactics of infantry that a radical improvement in the speed and accuracy of artillery fire was desirable. Men were no longer fighting in masses in the open, and they had found it more effective to offer only a fleeting target to the gun. Consequently the time required to load, run out, and aim the gun had to be reduced if the weapon was going to be of much use. Loading was enormously accelerated by the adoption of the single-acting breach mechanism, combined with a device for ejecting the empty cartridge case. The running in of the old gun to the firing position was necessary, because the recoil after firing was taken up by the gun and carriage as a whole. Hence, the weapon had to be run forward, set in position and re-aimed.

The Modern Gun

In the modern gun the barrel only moves, the energy of the recoil is taken up in an elastic press, and the barrel is returned to its original position by a spring. After firing, the modern gun returns instantly to the position it occupied before firing, and generally this does away with re-aiming. The improvements enumerated were first adopted by the French in 1897, and their famous 75-mm. gun can fire from twenty to twenty-five rounds per minute. Germany carried out an elaborate series of trials, extending over a long period, but it was only in 1905 that they adopted the quick-firing gun.

In the services the Maxims, Gatlings, and other automatic feed guns are not spoken of as quick-firers, that name being given to all weapons which are loaded by hand. Thus the 6-in. naval gun is a quick-firer and represents the maximum size of a quick-firing gun in the navy. The shell weighs 100 lbs., and can just be man-handled. The 7.5 in., the 9 in. and all heavier weapons are provided with regular hydraulic hoists and loading arrangements.

At the other end of the scale is the little 3-pounder, and from the 6-in. to the 3-pounder the firing arrangements are sensibly the same. Naval guns of greater than 6-in. calibre differ in the first instance from the 6-in. gun, in that the loading is done by machinery. With the main armament weapons of our battleships, the size and weight of the breech blocks renders it necessary to open and close the breech by hydraulic power; but the principle of the recoil arrangements is the same throughout.—Liverpool Journal of Commerce.

PREPARING FOR COMMERCIAL ASCENDENCY

THE question of Canadian manufacturers being able to supply to the fullest extent possible, immediately the munitions demand subsides, our own domestic requirements and develop concurrently and maintain an export trade that will transcend in volume all previous achievement, is one that should be considered and given tangible expression to now by individual or collective organization. We have organized for munitions production in a manner that has merited world-wide commendation. We can also organize for these others just as effectively, and without hampering in the slightest degree the meantime munitions production efficiency.

Organization for the manufacture of munitions was largely an individual firm affair, and, the Department of Trade and Commerce, Ottawa, notwithstanding, similar action is inevitable if we would corall in large part our domestic business and establish a world-embracing export trade. Evidence is not lacking that preparation is proceeding apace in the United States and even in Great Britain to not only maintain but to take hold of every available opportunity, both domestic and foreign.

In the United States, the American International Corporation has been organized with a capital of $50,000,000, and with the most prominent of that country's financiers and business specialists behind it. The avowed intention is to prosecute the most vigorous foreign trade expansion campaign in American history.

In Great Britain, irrespective altogether of the duration of the war, it is expected that in a very short time with the completion of the many large and specially-equipped munitions factories, there will be a wholesale release of firms, large and small, meantime engaged in the production of war material. By way of anticipating this, the Imperial Government, through the Prime Minister and Chancellor of the Exchequer, has stated definitely that the maintenance of a large and increasing export business is one of the essentials if victory is to be complete.

Export trade on Britain's part is, even now, war work, and the immediate future is ear-marked for its diligent prosecution. By no other means can her resources be husbanded and her efforts be so thoroughly concentrated on the task she and her Allies have undertaken to bring to its logical conclusion than that of retaining the world-wide commerce and market for her wares already established, and by enlarging their scope and service.

We have already hinted at the almost certainty of Canada's efforts lacking official Governmental backing. Under such circumstances individual firm enterprise must needs be forthcoming. Efficiency engineers, safety experts, and a myriad other departmental appointments have come to be recognized as part and parcel of our leading metal-working and general manufacturing establishments. May we suggest that a domestic and foreign trade department is now also highly desirable, manned by experts in each particular sphere, who will organize campaign plans, collect data, and generally arrange easy transition from war to peace-time pursuits.

Men fitted to grapple successfully with the problems of shell-making were neither hard to "spot" nor to develop, and we are of opinion that their prototypes having both a sufficiently wide commercial experience and intimacy with the manufacturing or practical side of any factory product, will be likewise as promptly available and as prolific of achievement.

Our plants generally are in a position with the cessation of hostilities to compass a greatly increased and more diversified output. To secure business in the coming time, to maintain full employment for men and machines will, however, necessitate "rustling" for both home and foreign orders. It should also be realized that war orders have increased the capacity and diversity of output of our competitors, making former competition none the less, but rather a great deal more. The need of organizing is therefore particularly and peculiarly urgent.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, Que., Dec. 13, 1915.—Reports from all sources continue to show that satisfactory conditions prevail throughout the steel, iron and metal industries, and while munitions are the chief feature of the activity, many other lines are in more or less good demand.

Pig Iron

Local conditions in the pig iron market are little changed from the previous week. Production continues at maximum capacity to supply the demands made upon the steel makers. In spite of the high prices, considerable inquiries are coming in from foundries. The question of transportation of both ore and iron is having a tendency to advance prices on some grades. A disturbing factor for the coming year is the possibility of a shortage in vessel tonnage for the shipment of ore.

Steels

The tension in the steel situation shows little indication of relaxation; in fact, the pressure upon producers seems to be increasing, and the period of future deliveries is constantly being extended. While bars and billets are principally in demand, the inquiries for bars, plates, etc., continue to increase.

Many mills are limiting orders to a proportion of customers' requirements, and in some instances inquiries are not even considered. Producers of steel have business booked for many months ahead, and in a great number of cases orders for second and third quarters of 1916 cannot be taken on.

The continued scarcity of tungsten keeps the figures for high-speed steel excessively high, and little relief is immediately expected. However, by the spring of next year, the situation may be somewhat relieved. Present quotations are $2.50 to $3.25 per pound.

Metals

The general condition of the metal market is dull, with prices firm. Local spelter shows a slight advance, while aluminum records another jump of 5c per pound. Present conditions will likely prevail until the close of the year.

Copper.—The lively condition of the copper market for the past few weeks has now ceased, and indications are that little change will be noted for the remainder of the month. Slight declines are quoted in the United States markets, but local prices are holding firm.

Tin.—No new developments have taken place during the past week, and the general dullness continues, with the possibility of a further slight decline before the opening of the New Year. A considerable supply of tin is in sight, and this has weakened the foreign markets. However, the local dealers are quoting last week's figures of 45 cents per lb.

Spelter.—Conflicting reports are being circulated regarding the spelter situation, and it would seem that speculators are trying to force prices up. It is generally conceded that recent advances are due to this, more so than supply and demand. However, the quiet condition at present tends to retain firmness, and, while foreign prices have declined somewhat, local dealers have advanced their quotations 1c per pound, which leaves the present price at 21c.

Lead.—The outlook from present conditions are that the market will show weakness in a short time, a decline being generally expected. Last week's quotation of 6¾c holds firm for the present.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

Antimony.—The market is steady and prices are firm at 42 cents per lb.

Aluminum.—The demand for aluminum continues to boost the price, and inquiries are numerous. Local dealers have advanced their quotations from 65 cents to 70 cents per pound.

Old Material.—Local scrap conditions remain unchanged, with a fair amount of transactions passing. Heavy melting steel scrap is quite active, and the demand is increasing. Present prices show an advance of $10 per ton over last week. The shortage of aluminum has advanced the price of its scrap to 27 cents per pound.

Toronto, Ont., Dec. 14.—There is little change to note in the general situation. The revival in trade continues and the outlook is distinctly favorable. The export trade is increasing in volume while domestic trade has improved considerably of late. Railways report substantial increases in earnings, and bank clearings exceed last year as also those of the previous year, which are favorable indications as to the increase in the volume of trade, and improvement in conditions generally. The shortage of tonnage and high ocean freight rates are a serious inconvenience to importers and exporters, and have not only increased the cost of certain products but have affected deliveries also.

The steel market continues very strong with every possibility of higher prices. The demand for steel for shells is increasing and is greater than the Canadian mills can produce. Preparations are being made for turning out the large-calibre shells which will call for a considerable increase in tonnage. The machine tool trade is active and dealers report very satisfactory business. In the metal market, tin and spelter have declined, otherwise prices are unchanged. The market generally is quiet.

Steel Market

The extraordinary activity in the steel trade continues and there is no sign of any recession. The steel companies have more business than they can handle and are booked up for months ahead. The demand is so much greater than the Canadian mills can supply that concerns working on shell contracts are obliged to buy raw materials from the States. It is stated that several large contracts for steel forgings and round steel bars which have been under negotiation between Canadian concerns and American mills are held in abeyance temporarily. It is understood, however, that the contracts will eventually be placed in the States. Under prevailing conditions, prices of steel are bound to advance, the market being very strong. Boiler plates have advanced again, and higher prices for domestic steel and iron bars are expected any time. There is no change in the situation with regard to American bars, shapes, etc., and prices are still withdrawn.

The galvanized sheet market is very irregular. Many makers have discontinued quoting on sheets on account of the fluctuations in the spelter market. Prices of black sheets continue to advance and all other materials used in the manufacture of galvanized sheets are also higher. Prices of galvanized sheets are very fair, and are expected to go higher.

Prices continue to advance in the States and the export demand is increasing. The French government is enquiring for thousands of tons of round steel bars. Many of the mills are increasing their capacity, but are as far behind as ever on delivery. Steel bars are quoted at 1.70c base, and iron bars 1.80c base, Pittsburgh. Billets continue to advance

on heavy demand. Bessemer billets are now quoted at $30 and open-hearth billets at $31 Pittsburgh. Forging billets are unchanged at $52, and wire rods are higher at $40 Pittsburgh.

Pig Iron

The pig iron market is very strong and prices continue to advance. A large percentage of the tonnage is going into steel, there being little demand for foundry grads. "Hamilton" and "Victoria" brands have advanced $1, and are now quoted locally at $24 per ton. The market for pig iron in the States is becoming excited and prices are advancing. "Grey Forge" is now quoted at $17.95 Pittsburgh. It is understood that quotations on "Lake Superior" iron ore for the coming season have been made. "Mesaba Bessemer" is quoted at $4.25, which is 80c above this year's basis. On "Mesaba non-Bessemer," 70c advance over this year is asked.

Old Materials

There is little change to note with regard to the situation in old materials. The market generally is firm with higher prices for heavy melting steel, aluminum and lead, while the various grades of copper have also advanced slightly. The market is not very active but there is a fair demand for copper and heavy melting steel. There is a continued scarcity of aluminum; this has strengthened the market for scrap metal.

Machine Tools

The market is very active and there is a good demand for machinery for shells, principally for the larger sizes. Some orders for 8-in. shells have been placed, and the concerns thus favored are getting their plants in shape for machining them. There appears to be a possibility of the situation as regards getting machine tools, being considerably relieved. There is a growing belief in the American market that purchases of machine tools for shipment to England will in the future be of comparatively small proportions. It is believed that munition making plants of Great Britain are now capable of meeting all requirements; the demand for tools is, therefore, less urgent. In this event, machine tools will be easier to obtain for this market and deliveries will be better. It is understood that Russia is buying a large amount of equipment, not only lathes, but practically a general line of tools.

Supplies

A few price changes have to be noted this week. Solder is down ½c. due to the continued weakness in the tin market. Linseed oil market is very strong and prices have advanced 2c, the new quotation being 87c for raw and 90c for boiled, per gallon. Turpentine is 2c higher and is now quoted at 87c per gallon High-speed twist drills keep on advancing and the situation is such that it is impossible to give a firm quotation. Business continues very good, there being an active demand for supplies from shell plants.

Metals

The market is quiet this week and lower levels for tin and spelter have again to be noted, other metals being unchanged. Copper is quiet, although the market is in a strong position. The lead market is quiet but firm. There is no change in the antimony situation, and the aluminum market is featureless. There is a continued active demand for metals for munitions, but ordinarily business is quiet.

Tin.—Although the primary markets are firm, tin is weaker locally and has declined 2c. There is a fair demand, but stocks are accumulating, which may depress the market. Tin is quoted locally at 43c per pound.

Copper.—The market is in a strong position, although quiet and unchanged. There is apparently a lull in demand, both for domestic and export. "Lake Copper" is quoted at 20¾c per pound.

Spelter.—The market is in a very peculiar condition, and it is difficult to size up the situation. There is good inquiry but sellers are not showing much disposition to do business. Spelter has declined 2c locally and quotations are more or less nominal at 18c per pound. Zinc ore is quoted from $80 to $105, Joplin, Mo.

Lead.—The market is quiet but firm at the "Trust" equivalent of 5.25c New York. The ore is quoted at $70 to $73, Joplin, Mo. Lead is unchanged locally at 7c per pound.

Antimony.—Conditions in the antimony market are unchanged. Spot stocks are scarce but futures are being freely offered at a concession of about 2c less than the spot market. Local quotations are unchanged at 40c per pound.

Aluminum.—There is no change in the situation. Supplies are scarce and the demand continues heavy. Quotations are nominal at 65c per pound.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Messrs. S. Ruperti and Alexsieff, care Military Attache, Russian Embassy, Washington, D.C.

CANADIAN EXPORTS TO GREAT BRITAIN

AN increase in imports from Canada of $34,697,000 and a decrease in exports to Canada of $20,498,000 during the first nine months of the present fiscal year is shown by figures for that period received by the Trade and Commerce Department from Commissioner Ray, of Birmingham. The total imports from Canada were $138,917,000, and exports to the Dominion $49,407,000.

Details are also furnished of the recent steps taken by the British authorities in respect to the requisitioning of all ships of British register, which regulations closely affect Canada. These show that rumors that the Government contemplates the requisitioning of the entire British mercantile marine are without foundation, but that power has been taken to deal, by the requisitioning of a sufficient number of vessels, with cases where an emergency of national importance exists at any particular market owing to the absence of tonnage, and, further, to regulate the employment of British shipping in the carriage of cargoes between foreign parts by means of licenses.

COMPENSATION ACT ADJUSTMENTS

A NUMBER of important changes in the grouping of industries under the Workmen's Compensation Act have been decided upon by the Workmen's Compensation Commission. The chief changes are a regrouping of the iron industries, in response to a request from employers; the separation of the manufacture of explosives from all other industries, and the uniting of all the building trades in one class. There has also been a rearrangement of railway, canal, roadmaking and bridgebuilding industries.

Theatres and moving picture houses, and the operation of elevators not in industries under Schedule 1, which had formerly been specifically included, are now excluded. The Board has also made the Act apply expressly to a number of industries hitherto considered to be covered by the general scope of the Act, but not expressly mentioned. The exclusion of machine shops, cabinet shops, and tinsmith shops with less than a specified number of employees has also been removed, and exclusion from the schedule

is permitted in regard to certain wood operations carried on for the most part by farmers and settlers, and to repairing or small building operations carried on by owners of rented houses or buildings. The changes come into effect on January 1, and will not affect employers during the present year.

The Board announces that employers must send in their next pay roll statement by the 20th of January. In the meantime a circular explaining the changes in detail will be prepared for distribution, together with the pay roll form for the coming year.

DOMINION COAL CO. ST. LAWRENCE SEASON

THE quantity of coal transported to St. Lawrence ports by the Dominion Coal Co. during the 1915 season of navigation was about 1,600,000 gross tons. In addition to this, something over 100,000 tons will have to be handled through Portland over the ensuing winter months, making a total for St. Lawrence ports of 1,700,000 tons.

A slightly larger quantity was transported to Montreal during the 1914 season, but the difference is accounted for by the fact that steamers formerly taking large bunker supplies to St. Lawrence ports were diverted to Sydney in the season just past, and bunkered either on their inward or outward voyage.

Steamers employed in the coal-carrying trade made 310 trips to St. Lawrence ports during the season of navigation just ended, and vessels from the Upper Lakes, as well as the seven seas, were secured in order to carry this large amount of coal at a time notable for shortage of tonnage.

POWER DEVELOPMENT AT MUSKOKA

THE Hydro-Electric Power Commission of Ontario has under way the extension of a power plant on the south branch of the Muskoka River. This plant, located at South Falls, and formerly operated to supply the town of Gravenhurst, has a single unit with a capacity of 450 k.w. It is being enlarged by the addition of a 750 k.v.a. unit. Excavation work was recently commenced and most of the equipment has been ordered.

Provision was made in the design of the existing plant for such an extension, and the installation of the latter does not alter the previous arrangement.

A wood stave pipe line, 100 feet long, will connect the existing headworks with about 60 feet of steel penstock leading to the new unit. The headgate mechanism, steel penstock, turbine, governor and relief valves are all being supplied by the William Hamilton Co., of Peterborough, Ont., the generator and the transformers by the Canadian General Electric Co., Ltd., Peterborough, and the wood pipe line by the Pacific Coast Wood Stave Pipe Co. The latter is being laid by the commission. Orders for the switchboard equipment have not yet been placed.

The extended plant will supply the towns of Gravenhurst, Bracebridge and Huntsville.

NEW ELECTRIC STEEL FURNACE PLANT

THE Canadian Electro-Products Co., whose incorporation with a capital of $500,000 was announced recently, expects to have a new electric furnace plant for the manufacture of high-grade steel in operation in Montreal in about a month or six weeks. The plant is being designed on the basis of two units, each of a capacity of 25 tons of steel a day, and at least one of these units should be in operation within the time mentioned.

The authorized capital of $500,000, it is understood, will be half in preferred and half in common shares, but only a portion of the authorized amount will be necessary for the initial installation. Probably $100,000 will be required to equip the plant to start with, and this is being subscribed privately.

J. S. Norris, of the Montreal Light, Heat & Power Co. and Messrs. Howard Murray and Julian C. Smith, of the Shawinigan Water and Power Co., are among those behind the new venture and will be members of the board of directors when organization is completed. The company, however, is a private enterprise, and will not be a subsidiary of either Montreal Power or Shawinigan Power. However, as the operation of the new plant, when both units are working, will call for about 4,000 h.p., naturally both the older companies will benefit, one as the distributor and the other as the producer of the power required.

The new venture represents a further extension of the electric furnace idea, which is playing so large a part in the increased consumption of power in this province. It has been applied to the aluminum and carbide industries in the Shawinigan district on a large scale. As applied to steel on the lines proposed, it is a new proposition here, but similar plants are in operation at Welland and Sherbrooke.

CANADIAN PURCHASES FOR FRENCH WAR OFFICE

Philippe Roy, General Commissioner for Canada, Paris, advises the Department of Trade and Commerce, Ottawa, that an order has been issued by the War Department of the French Government to the effect that all purchases made by the Supply Branch in Canada will pass through the Hudson Bay Co. Canadian producers should therefore submit their future offers through the office of that company at Montreal. It is further stated in Mr. Roy's communication that Canadian lumber, steel and meat will find in France an important market for years to come, but it is necessary that Canadian firms should have in Paris representatives entrusted with the necessary authority, especially if it is desired to secure Government contracts.

DOMINION TRADE RETURNS

AN expanding revenue and a decreased expenditure on consolidated account are shown in the November financial statement of the Dominion issued on Dec. 10. The total revenue to the end of November was $104,756,305.25, as against $90,468,002.68 for the corresponding period of last year, increases appearing under all heads, with the exception of excise. The consolidated fund expenditure dropped from $75,708,627 to $65,345,503.

Expenditure on capital account outside of the war outlay also shows a substantial reduction. The 1914 column shows no war expenditure, but the outlay last month under this head is given as $13,155,797, bringing the capital expenditure on war for the fiscal period up to $66,514,955. The total capital expenditure to the end of November was $91,475,889, as against $28,231,933 for the same period last year. The gross debt increased by $202,225,076, and stood at $829,377,292 at the close of the month. The funded debt payable in Canada rose from $774,060 in November, 1914, to $8,725,450 in November, 1915. The funded debt payable in England increased from $329,020,000 to $342,703,302. Temporary loans rose from $20,573,333 to $165,007,017.

Increases in the sinking funds and miscellaneous and banking accounts brought the total assets of the Dominion up to $327,709,125, as against $262,308,968, the total net debt thus standing at $501,668,167, as compared with $364,843,247. The monthly increase in the net debt was $9,139,675, as against $12,167,848, a decrease of $3,028,175.

Stratford, Ont.—The directors of the People's Telephone Co. have decided to purchase the Forest plant of the Bell Telephone Co. It is expected that the change will be made at the commencement of the New Year.

ONTARIO MINERAL OUTPUT

RETURNS made to the Ontario Bureau of Mines for the nine months, ending September 30, 1915, show an increase in value of gold of $1,884,093, and a decrease in value of silves of $2,051,760. It is pointed out that the increase in the production of gold amounts to one-third.

The gold districts of Northern Ontario, the report says, are fulfilling the prediction made several years ago that they would make good the loss caused by the waning of the silver mines of Cobalt. Thus, the combined value of the gold and silver output of the first nine months of the present year was only $167,661 less than for the same portion of 1914, notwithstanding the fact that the yield of silver fell off over 20 per cent. Part of this decrease is due to the low prices which prevailed during the whole nine months, but which made a sharp recovery in November.

The Sudbury mines are being worked to the maximum capacity, and the production of nickel for the nine months nearly equals the largest previous output for a full year. Over 75 per cent. of the output is made by the Canadian Copper Co., but the operations of the Mond Co. are now more extensive than formerly, and its output has correspondingly increased.

The yield of copper was also much greater than in the corresponding period of 1914 and nearly equalled the total output of that year.

New Incorporations

The Montreal Steel & Foundry Co. has been incorporated at Ottawa, with a capital of $150,000, to manufacture all kinds of machinery and mechanical specialties, appliances and instruments, at Montreal, Que. Incorporators: Emilien Gadbois, Joseph Marechal Nantel, and Charles G. Derome, all of Montreal, Que.

The Barrymore Cloth Co. has been incorporated at Toronto, with a capital of $250,000, to take over as a going concern the cloth manufacturing portion of the business of the Toronto Manufacturing Co., of Toronto, Ont. Incorporators: Edmund Percival Brown and Wm John McWhinney, of Toronto.

The Wood Products Co. has been incorporated at Toronto, with a capital of $100,000, to engage in the destructive distillation of wood and to manufacture charcoal, wood alcohol and all other products. Head office at Toronto. Incorporators: Arthur Wellesley Holmestead and James Leith Ross, of Toronto.

The International Steel Corporation, Ltd., has been incorporated at Ottawa, with a capital of $100,000, to manufacture, produce and deal in iron, steel and all other metals, at Toronto. Incorporators: James Richardson Roaf, Wm. Graham and John E. Mordon, all of Toronto, Ont.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Glace Bay, N.S.—The town council propose installing a pumping plant.

Hamilton, Ont.—The Monarch Machine Tool Co. will start work shortly on a war order.

Hamilton, Ont.—The Steel Co. of Canada, Ltd., will make considerable extensions to their plant.

Georgetown, Ont.—The Glass Garden Builders, Ltd., will erect a factory to cost about $25,000.

Montreal, Que.—The Williams Mfg. Co. will build a foundry at their plant on St. James street.

Hamilton, Ont.—The Dominion Steel Castings Co. will build an extension to their plant.

Bedford, Que.—A pumping plant will be installed in connection with the waterworks extensions now in progress.

Toronto, Ont.—The Board of Control will call for tenders for the supply and installation of a boiler at the municipal abattoir.

London, Ont.—The Battle Creek Toasted Corn Flake Co., Ont., will install electrical equipment to operate its machinery.

Halifax, N.S.—Work has been started on the erection of a steel plant for the Williston Steel & Foundry Co. Approximate cost, $16,000.

New Glasgow, N.S.—The Nova Scotia Steel & Coal Co. are building an addition to their steel plant at Sidney Mines, estimated to cost $100,000.

Fort Frances, Ont.—Russel Bros., machinists, have secured a contract for shells and will remove to Port Arthur where a plant will be equipped with the necessary machinery.

Edmonton, Alta.—G. W. Farrell & Co., of Montreal, Que., has signed a contract to supply power to the city. It will build a power plant and an electric railway to cost $6,000,000.

Arnprior, Ont.—The Galetta Power Co. are considering developing a water power at Long Rapids on the Madawaska river. A minimum of 13,000 h.p. could be developed at that point, but it would be difficult at present to dispose of so much power.

Quebec, Que. Fire damaged the Eastern Canada Steel Co. plant, St. Malo, recently. The cause of the fire is not exactly known, but it is supposed that it originated through an explosion in the furnace room. The damage, which is said to be around $100,000, is covered by insurance.

Grimsby, Ont.—T. D. G. Bell and his associates have formed a new company to be known as Bells, Limited, for the purpose of making war munitions. The new company has rented the necessary space and plant from the Bell Fruit Farms, Ltd., and the new machinery to make munitions will be installed in a portion of the factory.

Montreal, Que.—The manufacture of steel billets will shortly be begun by Montreal. Power-Shawinigan. interests, who have purchased the Record Foundry Building, and are now installing the necessary equipment. The concern, known as the Canadian Electro-Products Co., has secured its charter and machinery, including an electric furnace.

Stratford, Ont.—At a meeting of the Finance Committee of the City Council on Dec. 5, a committee composed of Chairman Ald. Henry and Aldermen Forbes, Mantle and Pauli, was appointed to sell the machinery which is being cleaned out of the basement in the Kemp factory, to make room for the recruits to the 110th Batt.

Municipal

Collingwood, Ont.—The proposed by-law in connection with Wilson Bros. has been withdrawn.

Toronto, Ont.—The Board of Control has decided to submit the hydro-radial to the ratepayers on Jan. 1.

Windsor, Ont.—A by-law is being prepared to sanction the expropriation of the Windsor Gas Co.

Islington, Ont.—Etobicoke Township ratepayers will vote New Year's Day on the proposed system of Hydro-radials.

Petrolia, Ont.—A by-law in connection with the proposed sugar refinery will be submitted to the ratepayers on Jan. 3.

Berlin, Ont.—The city council have decided to submit the hydro-radial bylaw to the electors at the January elections.

Chatham, Ont.—A by-law will be voted on by the ratepayers to sanction an expenditure of $10,000 on fire-fighting apparatus.

Chatham, Ont.—A by-law will be submitted to the ratepayers relative to granting concessions to the Dominion Sugar Co.

Baden, Ont.—The township council have decided to submit the hydro-radial by-law to the ratepayers of Wilmot Township on Jan. 3.

Chatham, Ont.—A by-law will be submitted to the ratepayers at the January elections regarding concessions to the Gray-Dart Automobile Co.

Sarnia, Ont.—A by-law will be voted on by the ratepayers on Jan. 3 to raise $120,000 for the purchase of the Sarnia Gas and Electric Light Co. plant.

Sarnia, Ont.—A by-law will be submitted to the ratepayers on Dec. 29 to authorize raising $12,000 to pay for waterworks extensions.

Tara, Ont.—A by-law will be submitted to the ratepayers on Jan. 3 to authorize an expenditure of $7,500 on a hydro-electric distribution plant.

Sherbrooke, Que.—The City Council contemplates alterations and improvements to the water power, electric transmission and lighting plants.

Listowel, Ont.—A by-law will be voted on by the ratepayers on Jan. 3, to authorize a loan of $12,000 to a company who propose to establish a boot factory here.

Cobden, Ont.—The town council will submit a by-law on December 27 to provide for the construction of a plant for the generation and distribution of power. Estimated cost, $20,000.

Princeville, Que.—The town council contemplates the erection of a pump station and the purchase of a 4-inch and 6-inch cast iron pipe, valves, pumps and hydrants.

Swift Current, Sask.—The City Council will engage an engineer to make a thorough examination of the pumping and waterworks system and advise as to what will be required to make the system thoroughly efficient.

Lindsay, Ont.—A by-law will be voted on at the January elections to authorize the granting of a loan of $15,000 to a

Large Shells : Production Problems and Possibilities--VI.

By C. T. D.

In preparing to undertake the production of large shells up to 9.2 in. dia., manufacturers will encounter problems of a nature altogether different from those connected with 18 pdr. shells. Automatic machinery will not be so applicable to the larger sizes, and productive ability will centre largely on such points as sequence of operations, tooling methods, etc.

An example of a special purpose machine is shown in illustration Fig. 18. This is a recently developed machine for performing the major operations on large shells, although its scope in finishing the minor operations such as recessing, grooving, tapping, etc., is limited by the ingenuity of the tooling outfit, and the commercial aspect of the operations performed.

This machine is known as the "Hart-Parr" lathe, swinging 26 in. over the vees, and capable of handling 9.2 in. shells rapidly and efficiently.

As can be seen in the illustration the machine is of massive design, the whole being characterized by simplicity of construction and directness of operation. Headstock and bed are cast integral, the former being of plain and rigid box type construction. The spindle is of exceedingly generous proportions, and is mounted in annular ball bearings of ample capacity.

The spindle drive is from a transverse shaft, one end of which projects in front of the headstock carrying a large diameter 4-step cone pulley, while the other end extends to the back of the headstock where a compact double gearing arrangement is mounted which transmits the power to a worm meshing with a large worm wheel fastened to the spindle.

The feed gear to the work carriage is of the simplest possible description. A pair of six-step cone pulleys are mounted on the tail end of the spindle, and a short intermediate feed shaft on the front of the bed. This intermediate shaft drives the main feed shaft through three pairs of gears, giving two working speeds and one quick return, which can be operated selectively in either direction.

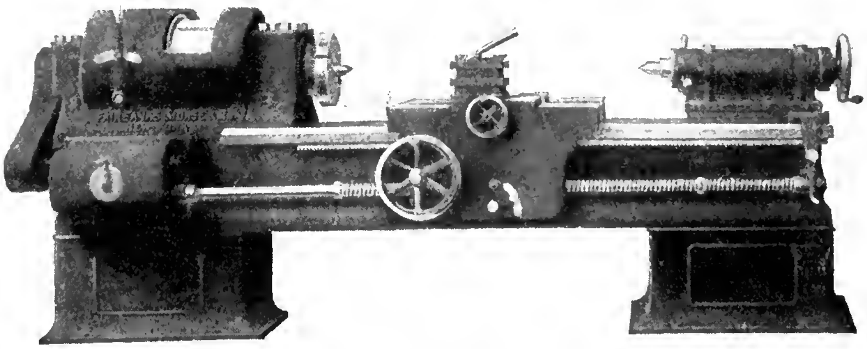

FIG. 19. HEAVY DUTY 26-IN. DOUBLE BACK-GEARED MANUFACTURING LATHE FOR SHELLS UP TO 12 IN. DIA.

The carriage is of the simplest possible description, hand and power traverse, and hand operated cross slide, carrying a four-sided tool box of the ordinary type.

When machining shell forgings, the open end of the shell is first cut off in any suitable machine with a reasonable degree of accuracy. The shell is then mounted directly upon the carriage on suitable supports, and secured by heavy clamps. The first tool head inserted in the ends of the spindle carries a single point tool which takes a roughing cut off the parallel portion of the bore, making it truly round.

By means of a special arrangement of drift, the first head is quickly removed, and another tool head, carrying a rough sizing reamer and a rough arch forming tool, is inserted. The cut thus obtained finishes the parallel portion of the bore to a fixed size, and rough forms the arch of the nose.

The next change of cutter heads brings into operation a finishing reamer which completes the forming of the interior arch. Three boring cuts thus complete the interior with the exception of recessing and facing which can be performed at the same time if proper tooling arrangements are provided. Should the forgings be exceedingly rough or out of truth, it may be found necessary to take one or two additional cuts.

The shell is now removed from the machine and mounted upon another of the same type, which is provided with an exceptionally stiff expanding arbor, thus truing up the work from the interior. A profiling cam is mounted on the back of the lathe in the now familiar manner which enables the entire trimming of the outside of the shell to be completed.

If suitable extra attachments are provided, it is possible to machine the groove and form the waved threads for the driving band, as well as boring tapping and threading the fuse opening in the nose. It is quite probable, however that these lighter operations can be accomplished to better advantage on lathes of ordinary types, leaving the entire productive ability of this machine to be concentrated on that work which it is cap-

able of handling to the greatest advantage.

This machine, which is being introduced to Canadian producers by the A.

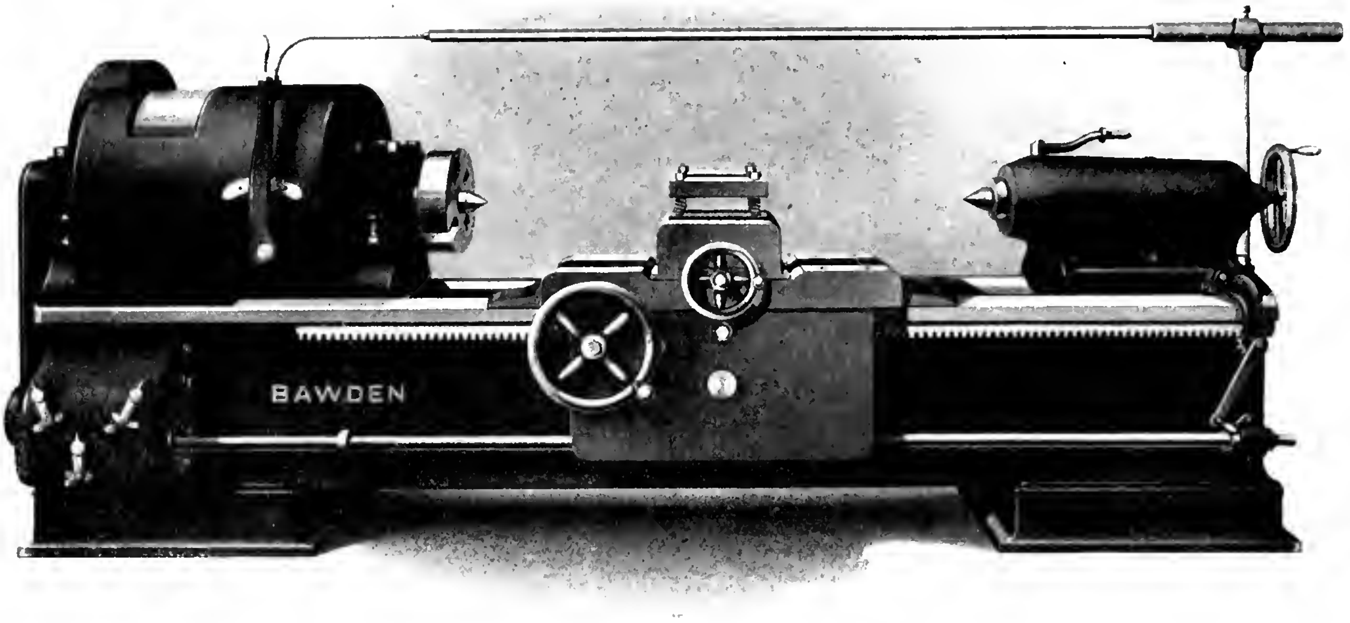

FIG. 20. TRIPLE-GEARED HEAVY DUTY SHELL LATHE WITH 26-IN. SWING AND SINGLE PULLEY DRIVE.

R. Williams Machinery Co., occupies a floor space of 5 ft. x 12 ft. and weighs 10,000 lbs. The swing over bed is 26 in. and over carriage $13\frac{3}{4}$ in.

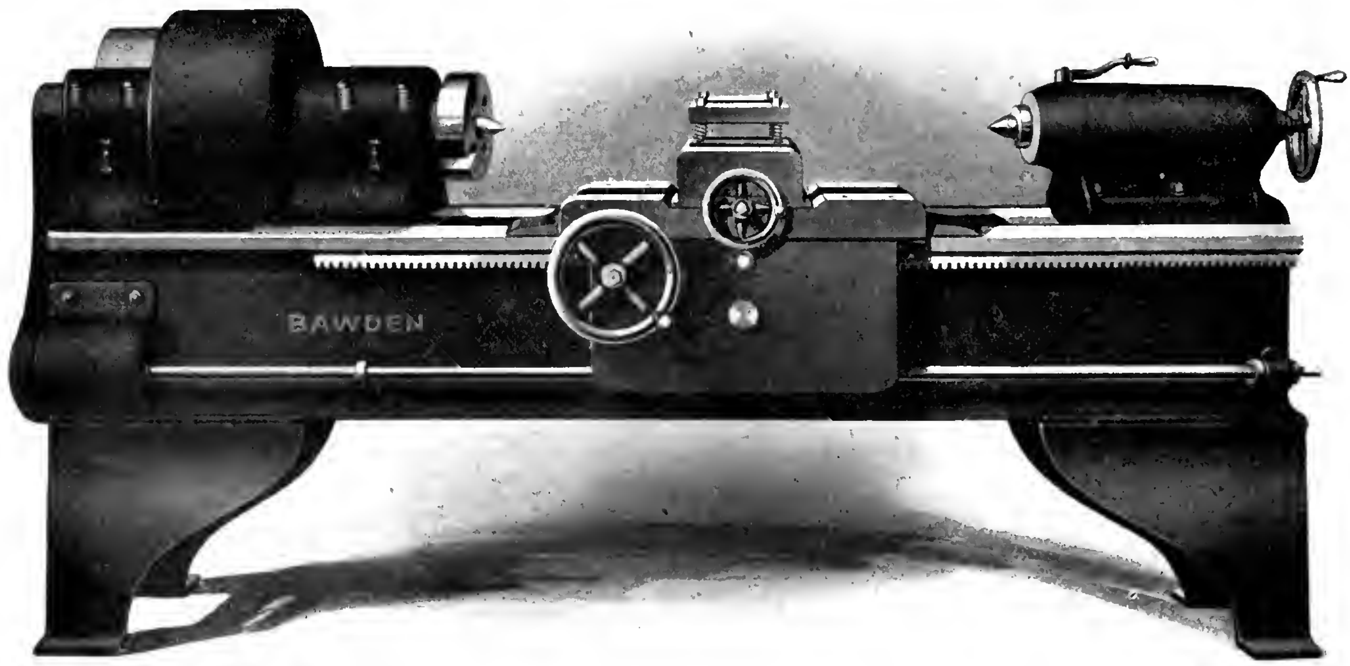

FIG. 21. 24-IN. HEAVY DUTY MANUFACTURING LATHE REDUCED TO 16-IN. SWING, FOR SHELLS UP TO 6 IN. DIA.

While the demand for lathes has been perhaps more continuous and insistent than for special purpose machines, such as band turning and threading devices, the large reserve of machines throughout the country at the origin of munitions activity prevented any immediate shortage. Since then, however, the extended scope of operations has given opportunities for the use of lathes of the plainest possible pattern.

Ample cutting power, accuracy, ability to stand up under continuous extra heavy duty, and simplicity and ruggedness of design to undergo rough treatment by unskilled labor, are the outstanding features of several lathes which are now being produced by engineering firms in various parts of the country.

Owing to the lapse of time which is necessary to the manufacture of a satisfactory lathe, these tools have not yet been completed in large numbers, but a very short time now will see deliveries

being made at a very gratifying rate.

Through the courtesy of the builders, particulars and illustrations of several

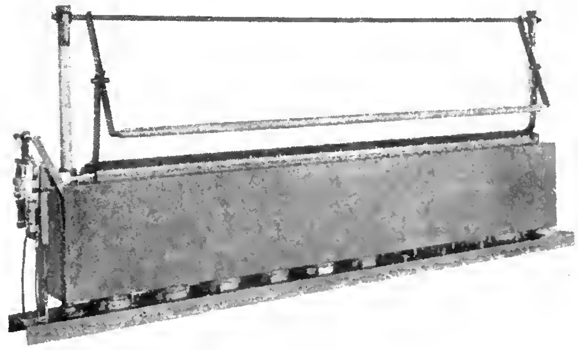

FIG. 23. ELECTRIC UNIT WITH HOOD DOWN AND SWITCH CLOSED, BAKING INTERIOR OF SHELLS.

of these lathes are published.

Engine Lathes for Large Shells

Fig. 19 is from a photograph of a heavy duty 26-inch double back-geared manufacturing lathe which is being built in this country and sold by the Canadian Fairbanks-Morse Co. It is built to meet the demand for a heavy serviceable lathe for the turning of projectiles up to 12 in. diameter.

The headstock, of the single pulley type, is of the rigid construction necessary for this class of work, the belt pulley being 20 in. dia. x 8 in. face, while the spindle bearings are chambered and ring oiled. With the use of a two-speed countershaft, six speeds are available, the back gear ratios being 11 to 1 and 8 to 1. If required, a 4-in. hole can be bored through the high carbon steel spindle which is accurately ground to size.

The bed is strongly reinforced with heavy cross ties of box pattern, and also has a longitudinal rib, having a cast rack, with which a pawl at the back of the tailstock engages, the advantage of such a positive lock being frequently apparent on heavy work.

The carriage is provided with four changes of feed from 1-32 in. to 1/8 in. power, and hand feed, both longitudinal and cross, being supplied. A square turret tool box is regularly furnished on the cross slide.

When supplied with a 12-ft. bed, this lathe weighs about 15,000 lbs., and takes in 60 in. between centres. The spindle has a front bearing 8 in. dia. x 10 in. long; the nose is 7 in. dia. with three threads per in.; and the centres fitted are No. 6 Morse taper. Regular equipment includes countershaft and necessary wrenches.

Fig. 20 illustrates a heavy duty lathe with a triple-geared head for shells from 8 in. to 12 in. dia., which is being produced by the Bawden Machine Co. of Toronto. The geared head is furnished with four-speed changes, with positive drive dog-tooth clutch. The belt pulley is 23 in. dia. x 7¼ in. face; the steel gears having a ratio of 26 to 1 and 18 to 1, all gears in headstock being bronze bushed. The high carbon steel spindle is hardened and ground and regularly furnished with a 2½ in. hole, the front bearing being 8 in. dia. x 9½ in. long.

The carriage has a bearing on vees of 42 in., and is regularly equipped with a heavy plain rest, with 4-post tool holder. Hand cross feed to slide with automatic longitudinal stop to carriage is standard.

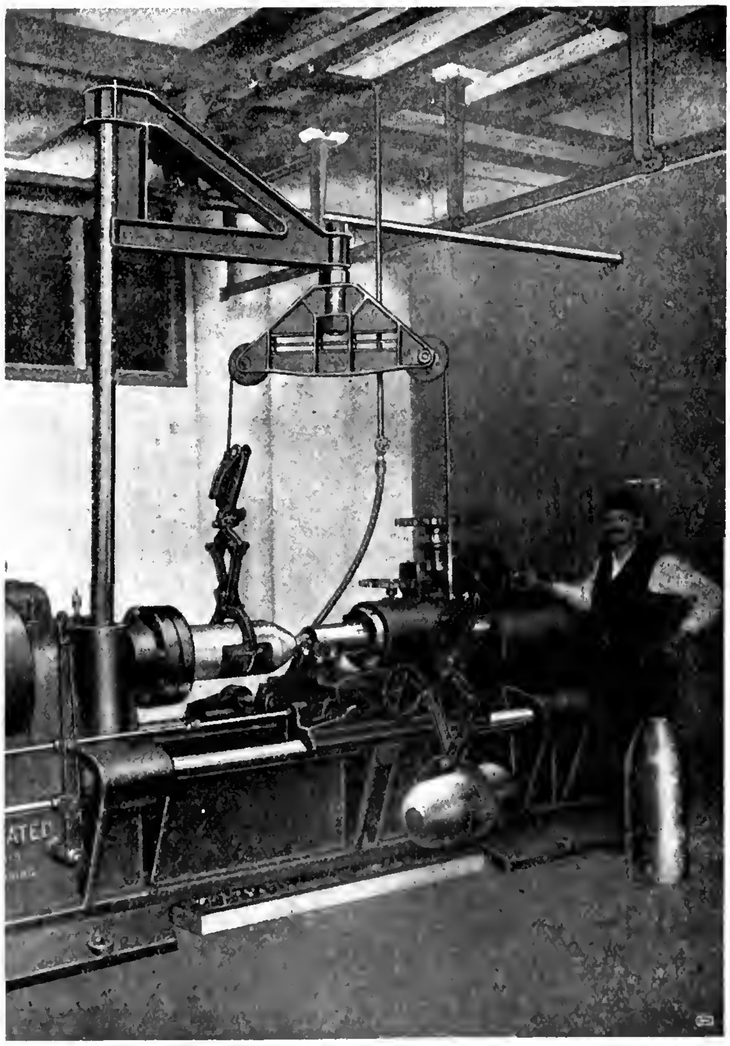

FIG. 24. POST CRANE WITH BALANCED TACKLE FOR LARGE SHELLS.

The quick change feed box supplies six feeds from 1-32 in. to 3/8 in. per spindle revolution, being driven by silent chain from spindle, and also containing feed reverse. The bed is very liberally proportioned, the width on top from front to back being 35 in., with two vees, one carrying the carriage and the other the tailstock. Planed surfaces are provided for receiving forming attachments, etc., on the back.

The tailstock is particularly rigid and carries a 3½ in. spindle. Both centres are No. 5 Morse taper. A driving face plate, plain tool post, and two-speed countershaft, with friction pulleys, complete the regular equipment.

Extra equipment can be supplied as follows:—Waving attachment, profiling attachment, 4 and 6-tool turrets on carriage, and 6-hole turret on bed.

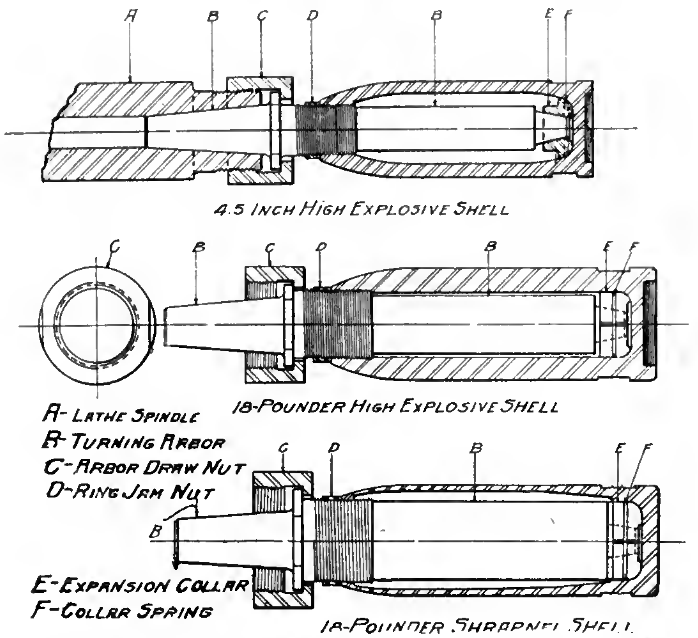

FIG. 25. SHELL ARBORS WITH EXPANSION NOSES.

The tailstock is a heavy offset pattern, with three heavy clamping bolts clamping the full length of bearing on the vee, and the spindle is 4¼ in. dia., having 9 in. travel with double thread on screw for quick traverse.

Complete equipment, including countershaft is supplied, the approximate shipping weight being 15,000 lbs. Extra equipment furnished to order includes taper attachment, forming or profiling attachment, waving attachment, four turret tool post, and heavy carriage turret.

Medium Capacity Lathe

For machining shells up to and including 6 in. size, the Bawden Machine Co. are also building a smaller size lathe, weighing approximately 3,550 lbs. This machine (see Fig. 21) has a bed 8 ft. long, swings 16 in. over vees and 10 in. over cross slide, the entire specifications, with the exception of the swing, being those of a 24 in. heavy duty lathe.

The single pulley has a diameter of 12 in. x 6 in. face, transmitting the drive through back-gearing with a ratio of 6½ to 1 to the spindle which has a front bearing 4½ in. dia. x 8 in. long. The bed is of the extra heavy duty type, 20 in. wide on top, with two vees like the larger machine.

A Unit Baking Oven

Baking ovens of large capacity, heated either gas or electricity, have been almost universally adopted for baking the enamel in the interior of high explosive shells. With the increase of size, the dead-weight of a load of shells has gone up very much. In addition to this, the use of large ovens for less than a full charge means a loss in economy, as full loads must be handled to get the most efficient use of the heat.

Other features become more marked as the shells increase in size, and interest accordingly attaches to a unit type of electrical heater, which overcomes troubles, such as broken lots, irregular operation, etc., recently developed by the

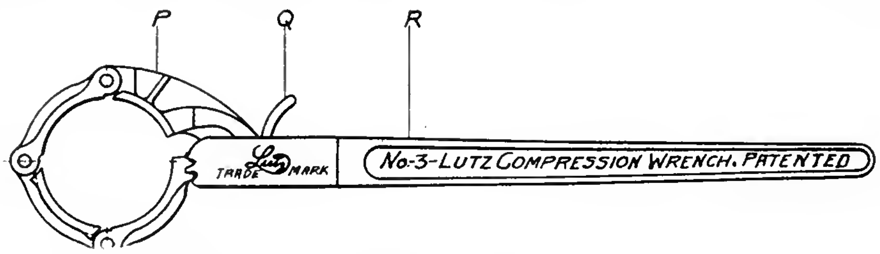

FIG. 26. COMPRESSION WRENCH WITH INTERCHANGEABLE GIRTHS FOR 3 IN. TO 8 IN. SHELLS.

Consolidated Car Heating Co., of Albany, N.Y.

This unit construction has been designed to withstand severe usage such as will be met with in baking large shells. The illustration, Fig. 22, shows the unit with the hood raised, the simplicity of construction being readily apparent. The shells rest on a channel iron base, above which is a sheet metal asbestos-lined hood containing the heating elements. When this hood is lowered into working position, the elements enter the interior of the shells, where they radiate the heat directly on to the surface to be baked, while the hood prevents excessive loss by radiation to the atmosphere.

Considerable economy in the use of current is thereby obtained, the time of baking in large ovens being reduced from eight hours to one and one-half hours.

Automatic control of the current is obtained through the control switch on the end of the hood. As the hood is raised to remove work, the switch is opened, preventing unnecessary waste of heat, and is closed again when hood is lowered.

The heating element is of a type which is giving excellent satisfaction on many electric railroads, and can be made to take any size of shell and any voltage or current up to 600 volts.

Handling Devices

The necessity for using mechanical methods in handling large shells has been promptly recognized by intending manufacturers, and satisfactory arrangements for this work will have an important bearing on the economy of pending operations.

Individual service is the principal requirement of machines in this work; any apparatus for lifting and handling must be immediately available for any machine. The use of transfer trucks with detachable platforms built for holding a suitable number of shells offers the most efficient and economical method of moving the work around the shop. The requirements of safety and care in handling render this method preferable to the use of other methods involving the use of slings or other suspension gear.

The adoption of overhead tracks depends on individual circumstances, style of shop construction, arrangement of shafting, etc., being controlling factors in deciding. The overhead installation in Fig. 18 is a good example of specialized arrangement where conditions are favorable.

All the benefits of such a system can

be obtained, however, by the adoption of single post cranes for lifting the work in and out of the machine, the moving of the work between various departments being done by any of the methods already in use.

An interesting device is shown in Fig. 22 which dispenses with the labor of operating chain blocks by hand. A 3-in. swivel post crane is mounted in a socket provided for the purpose on the headstock. At the end of the jib is a pulley yoke carrying a steel cable, at each end of which is a pair of lazy tongs. These tongs are connected to the cable by a lever which is arranged to take up a reasonable amount of slack in the cable. In operating the hoist, one pair of tongs is clamped on to the finished shell, while the other is fixed on a rough shell on the floor or truck platform. The lever is now used to take up the slack in the cable so as to lift the rough shell from the floor. As the difference in weight between the two shells is equal to the cut removed in the lathe, the operator merely has to lift this amount on the rough shell and swing it into place, while the finished shell is simultaneously swung clear and lowered to the ground, where it is safely deposited by letting out the slack on the cable. This device has been developed by the Amalgamated Machinery Corporation of Chicago, and is adaptable to any machine which can be provided with a crane.

Self-Acting Arbors

In machining shells up to 6 in. dia., frequent use is made of an arbor, part of which is threaded to receive the nose of the shell, which is then locked by a suitable driving washer or plate. The arbors shown in Fig. 23 have been specially designed for this work, and are fitted with expansion collars on the point which are brought into action as the base of the shell is tightened against them. These centre the shell accurately from the inside. The other end of the arbor is formed with a solid supporting collar, which, in conjunction with a draw nut, imparts added stiffness to the arbor.

The screwing of shells on and off the arbor is easily accomplished by the use of a compression wrench, Fig. 24. This tool has been developed by the Lutz-Webster Engineering Co., of Philadelphia, for use on shells up to 8 in. dia. The wrench handle is detachable from the girth or strap, various sizes of which are interchangeable on the same handle. The teeth on the end of the handle tighten up the girth when pressure is applied, the powerful compression gripping the shell firmly without damage to the surface in any way.

MORE CAR ORDERS PLACED

THE advancing steel market has stimulated ordering of railway equipment even in Canada, where buying has been light for some time. Another advance of 20 cents per hundred pounds will become effective on January 1st, and as a result of this several orders for equipment have been received within the last day or two by the Canadian Car & Foundry Co., while additional business is expected before the end of the month. The value of the new business was stated to be in the neighborhood of $750,000.

The increase in steel prices, although it has been gradual, has now mounted to a spectacular height. It is stated that the cost of building most classes of cars has increased 25 per cent. since last spring. The higher prices paid by car users does not, however, benefit the manufacturers, as they claim that the increase goes entirely into raw materials.

One of the new orders received by Canadian Car & Foundry Co. recently was from the Imperial Oil Co. It called for 100 forty-ton tank cars. Another was received from the Michigan Central Railroad. The Car Co. will make the steel underframes of 150 fifty-ton flat cars.

Outside of a large order for export to the British Government, very little foreign business has been closed. One order of 100 twenty-ton, end-tipping coal waggons, however, is announced to have been closed recently. The cars are for South Africa, where they are to be used on the Nigerian Railway.

BIG GUN ORDER TO UNITED STATES

THE big gun order which Canada expected to get from Great Britain as a result of an inspection of Canadian steel plants by British experts sent out for that purpose has been given in the United States. The order would have been a heavy one, and it was thought at first it would be placed in Canada, as Sir Frederick Donaldson and General Mahon, the British experts, intimated that their report on the adaptability of Canadian plants for big gun manufacture would be favorable. However, the War Office appeared to think that the remodelling of the plants would require too much time, and it has been learned that the order has since been placed in the United States.

Further Shell Orders

No further shell orders since the last big ones have yet been received by the Imperial Munitions Board, although such is the capacity of Canadian factories and machine shops that the board is in a position to handle a larger quantity than received. It is understood that representations to this effect have been made to the War Office, and it is hoped further orders will be the result. The board is also undertaking the handling of further orders placed in this country by the Allied Governments, but as far as learned has not yet received any. The Russian Government has already placed large orders, for the most part through the Canadian Car & Foundry Co., but the bulk of them have been distributed by this agency in the United States.

The French Government appears to be now manufacturing most of its own shells, and even in the United States has not lately placed any large orders. No orders for shells have yet been placed by the Italian Government, though there are said to be some in contemplation, either for distribution here or in the United States.

The last orders given to Canadian manufacturers included those for the manufacture of 9.2 and other such shells of much larger calibre than heretofore produced. As a result with the new equipment necessary Canadian factories will not be in a position to commence turning them out for some time yet in most cases.

CANADA'S TIMBER SUPPLY

ACCORDING to R. H. Campbell, director of the Dominion Forestry Branch, Canada's present supply of commercial timber has been variously estimated to be between five hundred and seven hundred billion feet, board measure, and to cover an area of approximately 170,000,000 acres. This estimate of quantity and area refers only to timber of commercial value as saw-timber. It does not include pulpwood, firewood, tie and pole material nor small timber of any description, although this has undoubtedly a very large commercial value.

The Commission of Conservation is engaged upon an investigation of the forest resources of Canada, which, when completed, will furnish the basis for a more accurate estimate of the amount of timber in the various sections.

Screwing and Tapping Aluminium.—The screwing and tapping of aluminium castings, states the Ironmonger, sometimes lead to trouble by the clogging of the chips between the teeth of the taps and chasers, but the difficulty can generally be overcome by the use of a suitable lubricant and the correct grinding of the tools. Tools used for turning and drilling aluminium should have acute cutting angles, and should be finally sharpened on an oil stone, as a keen edge is essential. Soapy water and petroleum are commonly used as a cutting lubricant. The latter enables a fine polish to be obtained, provided the cutting tool is properly ground.

The Development of Quick Acting Forging Presses--II.

By A. J. Capron, M.Inst. C.E.

The accompanying article formed the subject matter of a paper presented at the International Engineering Congress, San Francisco, last September. Recent progress and present status of the art of forging, together with the relative advantages of the quick-acting forging press over the steam hammer, constitute the salient features of the detail contents.

PART 1 of this article which appeared in our December 16 issue discussed at some considerable length the operation features of quick-acting forging presses. In the present instance, the wide variety product they can successfully handle is brought under review.

Fig. 3 represents a solid turbine-spindle forging made from an 80-in. (2,000 mm.) octagon ingot, weighing 116 tons, the finished weight of the forging being 55 tons.

Fig. 4 represents a turbine-drum, forged and expanded, made from a 64-in. (1,600-mm.) diameter ingot, weighing 85 tons, the weight of the forging being 35 tons.

Fig. 5 represents an hydraulic cylinder, forged and expanded. This forging required an 80-in. (2,000-mm.) ingot, weighing 116 tons; the finished weight of the forging was 63½ tons, and its rough machined weight as illustrated 42 tons. Its principal dimensions were:—

Length, 14 ft. 1 in. (4,200 mm.).

Diameter over collar, 6 ft. 6½ in. (2,000 mm.).

Diameter of body, 5 ft. 7 in. (1,700 mm.)

Diameter of bore, 46 in. (1,170 mm.).

For general forging work, all large presses, down to 2,000 tons power, should be fitted with mandrel gear, as that greatly facilitates the work under the press and the handling of the forgings. It can also be used conveniently for changing the tools when transverse tool-changing gear is not included in the equipment. For medium size presses of from 1,000 to 1,500 tons, a simple form of mandrel gear is often desirable and is generally well worth the comparatively small additional cost. Amongst the special classes of work for which presses have recently been adopted may be mentioned the following:—

Tyre Forging

For slabbing and punching tyre blanks presses have been adopted with very satisfactory results. Apart from the economical side of the question, it has been proved that tyres forged under the press give distinctly better results under test than the same steel forged under the hammer, and with the very high tests now called for in such material this is very valuable. The power of the press generally used for this purpose varies from 1,200 tons to 2,000 tons, but in one instance a press of 5,000 tons has been put down for this class of work. A press of this power can slab the largest tyre blank at a single stroke, and so is capable of a very large output. A 1,200-ton press, without any mechanical appliance for handling the blanks, has produced as much as 40 tons of wagon tyres, of 200 kilogrammes apiece, in an 11-hour shift, and 48 tons of locomotive tyres, of 600 kilogrammes apiece, in the same time.

More power is, however, preferable for this class of work, and recently presses of 1,500 and 2,000 tons have been more generally used. The most recent instance is a 2,000-ton press fitted with a manipulating gear and rotating table. The latter, which is mounted on a slide, enables the piece to be carried under the press and slabbed very rapidly by successive strokes, and the manipulating gear centres the blank so that the top punch can be entered correctly and then lifts it on to the bottom punch, ensuring a hole truly central and without the formation of any fin. This gear entirely dispenses with any manual work in handling the piece under the press, and also greatly increases the output.

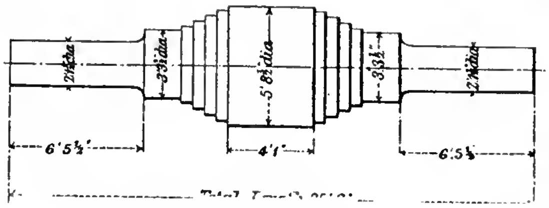

FIG. 3. SOLID TURBINE SPINDLE FORGING.

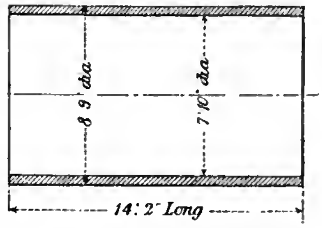

FIG. 4. TURBINE DRUM FORGED AND EXPANDED.

After the slabbing and punching, the tyres are frequently passes straight on to a roughing-mill before the final rolling in a finishing mill, but in some cases a second press is used for becking or expanding the tyres before rolling. This has the advantage of closing the material which has been stressed to some extent on periphery by the slabbing. For this process a press of from 500 to 800 tons is generally used, and is capable of an output of from 40 to 50 tons in a shift.

Disc Wheels

During the last few years the use of disc and Schoen wheels has extended very greatly, and consequently the forging of these is a matter of very considerable importance. For the forging of these, two methods have been adopted. One method is to use a press of sufficient power to forge the wheel in one or two operations, the top tool covering the whole surface of the wheel in the final squeeze. This necessitates a very powerful press, generally of about 8,000 tons. By the use of the quick-acting press, such wheels can, however, be forged under a press of much smaller power.

In several cases a 1,500-ton press, fitted with a rotating table for revolving the work, has been used. The top tool, which is about 300 mm. (12 in.) wide, is then made to the section of the wheel, so that, as the blank revolves, the successive strokes of the top tool on its surface shape the forging, and spread it over the whole surface of the bottom circular tool. This method effects a great saving in the first cost of the plant required for such work.

Axle Forging

In the past, axle-forging has been done chiefly under hammers, it being easier with hammers to get rid of the scale, and consequently to obtain a better surface. In several cases recently, quick-acting presses have been used for the first process of cogging the ingots and forging the axles roughly to shape, and as some governments and many railway companies require in the case of pressed forgings only half the sectional reduction that is called for when the ingots are cogged in a rolling mill or under a hammer, the use of a press for this purpose is additionally advantageous. The output of an 800-ton press in cogging from the ingot and rough forging is from 20 to 30 tons of axles in a shift.

For finishing axles, the difficulty of the scale, mentioned above, presents itself; but this has been to a great extent got over by the use of bracken or other suitable substance for detaching the scale, and by making the tools sufficiently wide

to prevent the scale which is detached from being pressed in. The finishing tools have generally three grooves about 12 in. (300 mm.) apart, and to obviate the objectionable side stresses that would come on the press when finishing in the outer grooves, an arrangement has been adopted of mounting the tools on slides worked by power, so that the top and bottom tools move simultaneously, and the grooves in use can be brought instantaneously to the centre of the press. For the first process of cogging and rough forging, the use of presses has proved very advantageous, and it seems likely that their use for finishing axles may also extend.

Cogging Ingots

Many presses have already been put down for the purpose of cogging ingots for special manufactures, the powers of press generally used being from 600 to 1,200 tons. Trials on special steels have proved that much better results are obtained by cogging such material under the press than by hammering or rolling. In the case, however, of steel of ordinary composition, but which is required to be of specially close and uniform texture, as, for instance, for the manufacture of material which has to be drawn, it is found that cogging under the press, prior to the subsequent processes of rolling and drawing, produces a very great improvement in the texture of the steel. So marked is this improvement that in some cases a comparatively small reduction under the press in the original sectional area of the ingot proves sufficient to give the desired result.

Shell-Forging

For the purpose of forging externally armour-piercing shell up to the largest calibres at present required, quick-acting presses of from 1200 to 2000 tons have been used to a considerable extent. For the processes of piercing and drawing, which require a long continuous stroke, purely hydraulic presses worked from an accumulator are much more suitable.

General Forgings

For the production of engineers' and other general forgings an up-to-date quick-acting press has really no competitor. Its general advantages over the steam-hammer have been already enumerated, but it is only by experience of its capabilities in actual use that its superiority can be properly realized. For the manufacture of forgings of simple form where large quantities are required, dies can be used, and in many cases the forgings can be produced by a single stroke of the press. Dies can often be used in the case of forgings of more complicated form; but then it is generally necessary to forge the piece roughly to shape before using the dies to produce the exact shape and dimensions required. This point is particularly mentioned because die forging can be done much more advantageously under a press than under a hammer, providing there is a fair body of metal.

Generally speaking, it is only quite small forgings, and especially those of very light section, which are best made under a hammer or drop-stamp. With a press, the tools and dies can be of a cheaper and lighter construction, and they last much better than when used under a hammer. For many special manfactures requiring a considerable number of similar forgings, so that special tools and dies can be provided, the use of high-speed presses has proved extremely advantageous. Amongst such applications which have already been made, the following may be mentioned:

For locomotive and railway works, for general small forgings, including coupling and connecting rods, presses of 150, 500 and 600 tons.

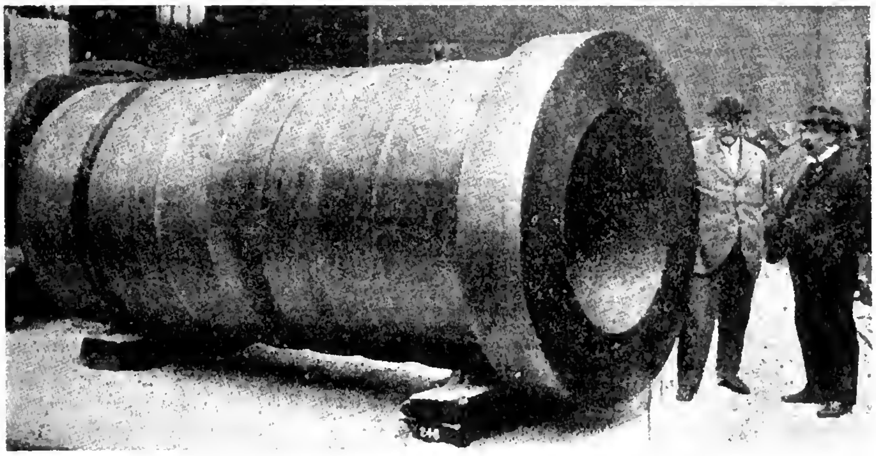

FIG. 5. AFTER ROUGH TURNING, FORGED AND EXPANDED HYDRAULIC CYLINDER AFTER ROUGH TURNING.

For stamping crossheads and other forgings required for boiler-feed pumps, a 600-ton press.

For stamping field-gun carriage forgings, a 500-ton press.

For bridge and structural work, for such as stamping link ends, presses of 150 and 300 tons.

For shipbuilding works, 300 and 500-ton presses.

For anchor-forging, an 800-ton press.

For forging well-boring tools, an 800-ton press.

For the manufacture of tires of a flat rectangular section for road vehicles, for the first process of slabbing and punching, and for the second process of expanding or becking, presses of 400 tons, of special construction.

Apart, however, from special application, presses of small and medium powers are beginning to be used to a very considerable extent for general engineers' forgings, both in forges and in engineering works. The powers that have so far been used for this purpose in engineering works range from 150 to 800 tons, and in forges up to 1500 tons, and it can be safely stated that such presses have proved generally very profitable.

In an engineering works it is often preferable to have the facility for producing the smaller forgings especially required when repair work is undertaken, and the much wider range of work that can be done under a press than a hammer is a substantial advantage.

In a forge, it is desirable to have a sufficient proportion of presses of medium power, as it is generally possible to keep such presses more uniformly employed than the heavier presses, and the production is naturally more economical when the power of the press is proportionate to the size of the forging.

In several cases, 300-ton forging-presses have been installed in steel-rolling mills for doing general repairs, and they have proved exceedingly serviceable for this purpose in enabling breakdowns, which are liable to occur with such machinery, to be dealt with very promptly on the spot, and thus greatly reducing the stoppage of the mill or other plant.

Another application which is of interest is the use of quick-acting presses for the manufacture of iron from the puddling furnace. With presses of sufficient rapidity of action, very satisfactory results have been obtained both in quality and output, the powers of presses generally used for this purpose being 400 and 500 tons. For naval repair-ships, forging-presses of a specially compact construction have been used, generally of 150 tons power. The advantages of a press for this purpose are that, unlike a hammer, its working causes no inconvenient vibration or damage to the structure of the ship, and that it is capable of dealing with repairs of a far more extensive character.

In conclusion, it may be stated that the superiority of presses over hammers

for the heavier classes of work has been recognized for the past twenty years, and their use frequently adopted; but within the past ten years, owing largely to improvements in construction, and particularly to increased speed of working, their use has become much more general, and it is only within this latter period that presses of medium and small powers have proved a practical success and have begun to be freely adopted.

Forging-presses of all powers, and particularly of medium and small powers, will undoubtedly come into much more extensive use in the near future, as foreshadowed by the advance made during the past ten years, and more especially because the increased speed of working that has been attained opens so much wider a field for their useful application.

THE USE AND ABUSE OF OILS.—I.*

By T. C. Thomsen, B.Sc.

THE owners of many large plants have seen the advantage of having an engineer responsible for the lubrication of their engines and machinery, and in plants which are not large enough to justify the employment of an engineer for this particular work, it has been found advantageous to have a lubricating engineer to inspect the plant occasionally, report on the lubricating conditions, and offer suggestions as regards economy and saving in power.

Many large concerns, when inviting tenders, specify certain chemical attributes in the oil. This practice is wrong, because chemical readings do not show the lubricating properties of an oil, for the reason that it is possible to duplicate a high-grade oil on the basis of chemical tests by means of an imperfectly manufactured and inferior article. Although the chemical tests may be the same for the two oils, the results can be widely different in actual work. The only accurate way of testing lubricants is to try them under working conditions, where they are to be actually used.

High-grade Oil and Lubrication Cost

The question might be asked whether introducing a higher grade of oils would not increase the total cost of lubrication. Experience has proved that in a large number of plants the costs of lubrication over a period may even be lower than with lower grades of oil in use. In other cases the cost may possibly work out a little higher, but this increased cost will be balanced by other benefits. It is here that the services of a lubricating expert become desirable. He should select high-grade oils for the portion of the plant where such oils could be used to advantage, and if the lubricating conditions are not favorable to the introduction of high-grade oils, he may suggest ways and means by which better lubricating appliances or better methods of handling oil can be introduced, so as to make the introduction of better grades of oil possible.

When talking to men directly interested in the successful running of machinery, one is often assured that they have no trouble; the idea being that the machinery is operating without any unusual heating of bearings or engine parts. In many such plants, however, the mere change from low-grade oils to better grades has effected a saving in power of 20 per cent., and it is now realized that there is something beyond having "no trouble." A troublesome bearing in nine cases out of ten will not indicate that the oil is unsuitable, but that some mechanical defect exists in its construction. It is not an occasional hot bearing, but the few degrees of unnecessary frictional heat that are wasted in hundreds and hundreds of bearings that determine real standard of lubrication.

Testing Influence of Better Lubrication

The actual testing of the influence of better lubrication on a power-house plant is a difficult matter, as there are so many other conditions that may influence the results. By means of accurate temperature tests it is, however, possible in nearly every case to make a comparison between the lubricating qualities of different oils, and it is recommended to make such tests as thorough and as careful as possible on specially selected important bearings. These temperature tests should be repeated from time to time with a view to controlling the quality of the oils in use. If the mechanical conditions do not change, the rise in temperature of the bearings above the surrounding atmosphere should remain nearly constant.

When a new motor exhibits a tendency to develop heat in one bearing, the bearing should, of course, be examined. If it is found in good condition, the cause of the heating will probably be found in the thrust of the armature shaft against the bearing, which may result from either of two conditions: First, the machine may not be level, and the armature shaft may dip towards that end. Second, the magnetic centres of the pole-pieces and armature shaft may not be in line.

Where low-grade mineral oils, or oils with mineral base, but compounded with animal or vegetable oils, are employed, they will develop gumminess in the bearings, and necessitate frequent cleaning. Such cleaning is unnecessary when high-grade dynamo oils are employed; cases have been known where such oils have been in use for years without any necessity for cleaning the bearings and oil wells. However, it is desirable to empty the bearings every three or four months and put the oil through a suitable filter. It will then be as good as new, and can be used over and over again, being mixed with a little fresh oil to make up for loss.

*From a paper read before the Association of Mining Electrical Engineers.

CAST VANADIUM STEEL DIES

THE use of alloy steel castings for dies has lately come into prominence due to important developments which have been made in the last years by steel foundries specializing in such material. Cast steel dies are now being used by drop forging manufacturers, by plow manufacturers for making plowshares, and by sheet metal workers for forming dies in the production of sheet metal specialties, kitchen-ware, etc. Various alloys have been tried for cast steel dies, but, according to C. R. Messinger, vice-president Sivyer Steel Castings Co., Milwaukee, the most satisfactory material so far introduced is vanadiem carbon steel.

The Sivyer Company has made a specialty of cast vanadium carbon dies under the name of "Sivyer" die steel. Exceptional wearing qualities are reported, together with unusual resistance to cracking or breaking under the battering to which dies are subjected. For example, a run of 40,000 automobile brake support forgings 20 in. long, was made from a pair of Sivyer dies without, it is stated, any great amount of wear. In another instance, a plow manufacturer claims that his dies last at least six times longer than cast-iron dies for forming plowshares, and are considerably cheaper than hammered blocks.

For general drop forge work the company considers the best practice is to cast the dies with the tenons and with the impressions for breakdowns approximately to shape, allowing a small amount for finish. The impression for the die is then sunk in the solid block. For plain forgings, the impressions also are sometimes cast in the dies, allowing some metal for finish. In dies for making plowshares the entire impressions are cast in the dies, allowing about ¼ inch metal for finishing. Forming dies for sheet metal work are also cast approximately to shape with some allowance for finishing.

After annealing and machining, the general practice with cast vanadium dies is to heat to 1500 or 1550 deg. Fahr., and quench in oil for a fairly hard surface and in salt water for a hard surface. In most cases no additional heat treatment is required; that is, the temper should not be drawn.

Cast vanadium dies, it is explained, generally cost a little more per pound than hammered carbon blocks. However, it is held that the saving in material from casting approximately to shape more than counterbalances this, and in addition there is less material to be removed.—Iron Age.

The Lay-out of Ships Ventilator Cowls, with Girth Seams

By J. W. Ross

While the methods described in the accompanying article have immediate reference to work in connection with shipbuilding, the adaptation of the principles involved are applicable to many manufacturing lines. Exhaust systems in shops and mills offer occasional instances where such work may be necessary, but the fact that such instances are occasional, renders a clear understanding of the procedure to be followed all the more desirable.

THE perspective view, Fig. 1, shows a girth seamed ventilator cowl. Its visual effect is not so pleasing as that of the hammered or blocked out type with the longitudinal seams. However, its chief advantage lies in economical construction.

The Outline Construction

Measure off the base line, A B, Fig. 2, equal to 20 inches. Locate the point C on the continuation of the base line, equal to ½ the distance of A B. With centre C and radius C B, strike the quadrant B E. The point D is located by measuring from C a length equal to half the distance B C. Erect the perpendicular F D. With radius equal to twice the length of A B, and at centre E, strike the arc to intersect the perpendicular D F, thus locating the point F. Connect F to E. With radius equal to D A and with F as centre locate the point G. With G as centre and the same radius strike the quadrant F L H, tangent to the perpendicular A J.

In this cowl there are five courses. Count each end course as one and the intermediate courses as two each. Therefore this total of the courses will be 8. Divide the outline A K L F into 8 equal parts. At the first division point locate J. Then take two parts and locate K. Two parts again for L. Similarly for M. Divide the quadrant B E into the same number of parts.

The point W is located at the first division point. P is denoted by taking two parts; similarly locate the points Q and R. Connect the points J W, K P, L Q and M R. These lines are rivet lines. Bisect the rivet lines, locating the points X, S, T, U, V and W. Connect the points A to J, J to K, L to M, and M to F, by straight lines. These lines are drawn in showing each course with its overlaps, looking downwards. Connect the points on the throat in a similar manner. This completes the side elevation.

The front elevation is projected over, although it is not essential to the development of the patterns.

Prolong the base line A B to Fig. 3. Erect the perpendicular X^1 F^1. Draw the projecting line F F^1 parallel to A X^1. This locates F^1. Also parallel to A X^1, project the point W, Fig. 2, to its intersection of the axial line X^1 F^1, thus locating W^1. With centre W^1 and radius W^1 F^1, draw the circle defining the mouth of the cowl.

By parallel line to A X^1 project over all the centres S, T, U, V, Fig. 2, to the

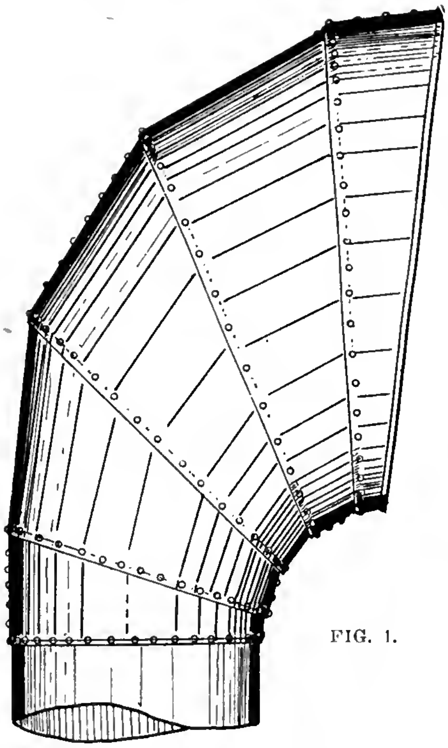

FIG. 1.

points S^1, T^1, U^1, V^1, Fig. 3. With radius V M Fig. 2, and centre V^1, mark off the distances V^1 V^2. Measure off U^1 U^2, Fig. 3, equal to U L or U Q, Fig. 2. Similarly locate the distances T^1 T^2, S^1 S^2 and X^1 X^2, Fig. 3, by the respective distances T K, S J and X A, Fig. 2. Connect the points X^2 to S^2, S^2 to T^2, T^2 to U^2, U^2 to V^2 and V^2 to W^2. This completes the front elevation.

Triangular Construction

As no two courses are alike, a separate development will be required for each course. One of the courses, therefore, will be herewith developed, the others being developed in precisely the same manner.

Let course III be selected for development. To save confusion of lines, transfer carefully the outline of the course III —as represented by the letters K, L, U, Q, P, T—Fig. 2, over to Fig. 4.

With centre T and radius T K or T P describe the half section view K 5 P. Divide this semicircle into a suitable number of equal parts; the greater the number, the more accurate the templet. In this case it is divided into 8 equal parts. Project all these points to, and at right angles with K, T, P.

With U as centre and radius U L or U Q, describe the half section view. L 5^1 Q. Divide this semicircle into equal parts, the same number as that used for the semicircle K 5 P.

Erect perpendiculars from L U Q to these division points. Number the division points on both circles in consecutive order and in relation to one another. Also number the projection points on the lines L U Q and K T P in respect to their relative projection lines. Connect the points 2^2 to 2^3, 3^2 to 3^3, 4^2 to 4^3, etc., by straight lines.

If both of the half section views were equal, these straight lines, 2^2 2^3, 3^2 3^3, etc., would be shown in the drawing by their true lengths. However, the sec-

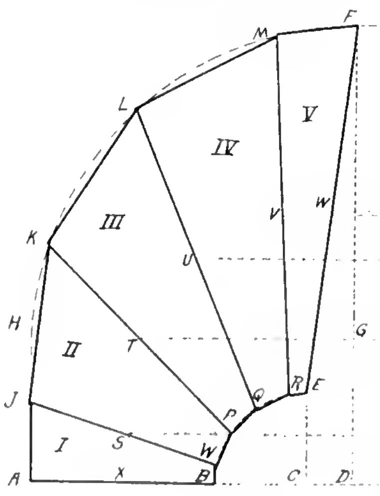

FIG. 2.

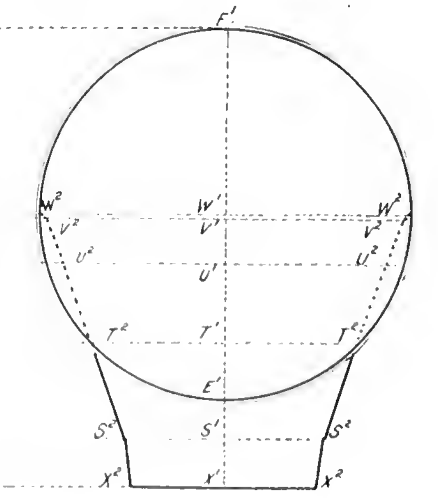

FIG. 3.

tions are not equal, therefore the lines in question will be foreshortened.

Their true lengths are found by triangulation, as follows: Draw the horizontal line 2^3 8^3, Fig. 5. Erect perpendiculars at any point, as at O. Measure off the perpendicular O 2^2, Fig. 5, equal in length to 2^3 2^2, Fig. 4. Take the difference of the lengths of the projector lines 2^2 2^1 and 2^3 2, Fig. 4. Place this difference on the horizontal line, as O 2^3, Fig. 4. Connect 2^3 to 2^2, Fig. 4. This line is the true length of the foreshortened line 2^2 2^3, Fig. 4.

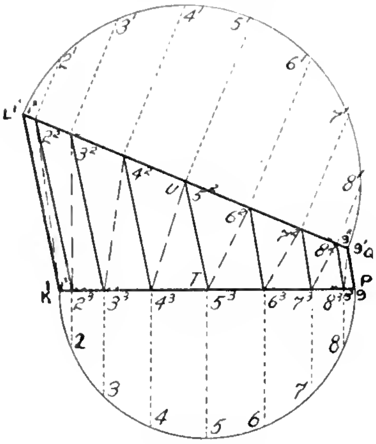

FIG. 4.

Take the distance 3^2 3^3, Fig. 4, and place it on the perpendicular O 3^2, Fig. 5. Measure 3^3 3, Fig. 4, against 3^2 3^1, and place the difference, as O 3^3, Fig. 5. Connect by a straight line 3^3 to 3^2. This inclined line, or the hypothenuse of the right angle 3^3, O, 3^2, is the true length of the foreshortened line 3^2 3^3, Fig. 4.

Again, make O 4^2, Fig. 5, equal in length to 4^3 4^2, Fig. 4. The base of the triangle O 4^3, Fig. 5, is equal to the difference in length of the projectors 4 4^3 and 4^2 4^1. The hypothenuse, 4^3 4^2, being the true length. Proceed in a similar manner with lines 5^2 5^3, 6^2 6^3, 7^2 7^3, and 8^2 8^3, Fig. 4, locating the true lengths by the inclined lines 5^2 5^3, 6^2 6^3, 7^2 7^3 and 8^2 8^3, respectively, Fig. 5.

In Fig. 4, connect the points 1^3 to 2^2, 2^3 to 3^2, 3^3 to 4^2, and 4^3 to 5^2, etc., as shown by the short dash lines. These lines are also shown foreshortened. Their true lengths are obtained in a similar fashion as the other lines. Draw the horizontal line 1^3 8^3, Fig. 6. Erect perpendiculars at the points X. Measure off X 2^2 equal in length to 1^3 2^2, Fig. 4. The distance X 1^3, Fig. 6, equals 2^3 2^1, Fig. 4. Connect by a straight line the points to 1^3 to 2^2. This line equals the true length of the foreshortened line, 1^3 2^2, Fig. 4. Transfer the distance 2^3 3^2, Fig. 4, over to the perpendicular X 3^2, Fig. 6. Measure off X 2^3 equal to the difference of the projectors 2^3 2 and 3^2 3^1, Fig. 4. The points connected, 2^3 to 3^2, by a straight line defines the true length. Again, transfer the distance 4^3 4^2 over to X 4^2, Fig. 6. Obtain the difference between the projectors 3 3^3 and 4^2 4^1, and place at X 3^3, Fig. 6. The true length is shown by the line 4^2 4^3. In a similar manner define the true lengths of the remaining dash lines.

Having obtained all the true lengths, the development of the plate will be next proceeded with.

Plate Development

In this course it is decided to have the vertical seam on the line 9 9^1. Therefore, the centre line of the pattern will be 1^2 1^3.

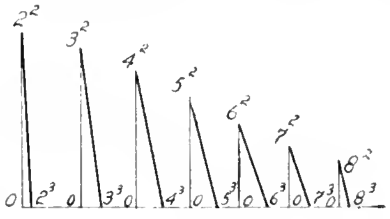

FIG. 5.

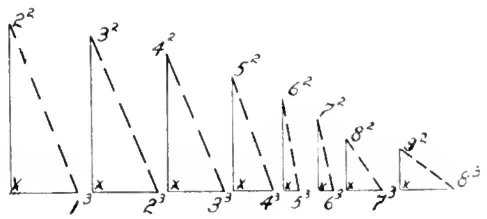

FIG. 6.

Measure the vertical line 1^3 1^2, Fig. 7, equal to its true length 1^2 1^3, Fig. 4. Set the dividers to the distance 1^3 2^3, Fig. 6, and transfer over to Fig. 7 by using 1^3 as centre and striking the arc at 2^2. By careful measurement obtain the exact length of the arc between the division points on the semicircle L 5^1 Q, as 1^1 to 2^1, or 2^1 to 3^1, Fig. 4. All the divisions being equal, it is a matter of indifference which division length is taken. With the dividers set to this distance, place one point on 1^2 and strike the intersecting arc at 2^2, Fig. 7.

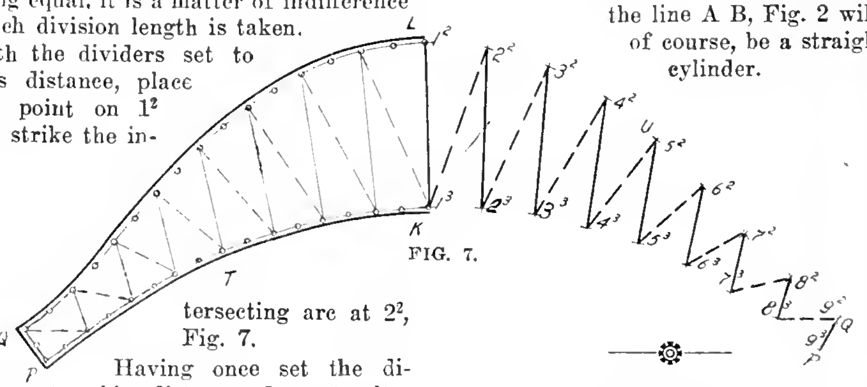

FIG. 7.

Having once set the dividers to this distance do not alter them, but put them aside for the time being. Procure another set of dividers and take the distance 2^3 2^2, Fig. 5. Transfer to Fig. 7. With one point on 2^2 strike the arc at 2^3. Now measure carefully the length of the arc, between the division points, on the semicircle K 5 P. Transfer this length to Fig. 7 by placing one point on 1^3, striking the intersecting arc at 2^3. Hold these dividers at this distance.

Again, procure another pair of dividers; that is three pair of dividers in use. With centre 2^3 and distance 2^3 3^2 equal in length to 2^3 3^2, Fig. 5, strike the arc at 3^2, Fig. 7. Now with the first pair of dividers strike the intersecting arc at 3^2. Of course, 2^2 3^2 is equal to 1^2 2^2.

With No. 3 dividers transfer the distance 3^2 3^3, Fig. 5, to 3^2 3^3, Fig. 7. With the No. 2 dividers on point 2^3 strike the intersecting arc at 3^3, Fig. 7. With centre 3^3 and radius 3^3 4^2 equal to 3^3 4^2, Fig. 6, strike the arc at 4^2. With 3^2 as centre and radius 3^2 2^2, strike the intersecting arc at 4^2, Fig. 7. Proceed in a similar manner with the remaining lines. Care being taken to have all the distances 1^2 2^2, 2^2 3^2, 3^2 4^2, 4^2 5^2, etc., Fig. 7, equal to each other, also equal to the divisions of the semicircle L 5^1 Q, Fig. 4. Then the length of the curve through the points from 1^2 to 9^2, Fig. 7, will be equal to the length of the semicircle L 5^1 Q.

Similarly the divisions 1^3 to 2^3, 2^3 3^3, 3^3 4^3, 4^3 5^3, etc., Fig. 7, are equal to the divisions of the semicircle K 5 P, Fig. 4; then evidently the curve line 1^3 to 9^3 will be equal in length to that of the stretchout of the semicircle K 5 P, Fig. 4.

On the right of Fig. 7 the construction lines are shown. On the left the curves are shown drawn in. These curves are the rivet lines to which is added suitable laps. The rivet holes are spaced off accordingly. The location points, 2^2, 3^2, 1^3 2^3, etc., may be used for rivet centres. Other centres being spaced in as desired.

This completes the templet for course III. The other courses being developed in exactly the same manner.

The continuation of the pipe below the line A B, Fig. 2 will, of course, be a straight cylinder.

Labor Conditions.—The report of the Dominion Labor Department for November indicates that labor conditions are very good, due to the war orders, the crop movement and the fine, open weather. There were only two small labor disputes, affecting less than fifty workers, one in Halifax and the other in Victoria.

NEW PROCESS DEVELOPMENTS

Inventive Genius and Research Operate to a Dual End — They Aim to Improve What We Now Possess and Bring to Our Service Commodities Before Unknown

THE MANUFACTURE OF LEATHER BELTING.—I.*

By F. H. Small.**

THE manufacture of leather belting has its beginnings on the farms of New England, the grazing ranges of Argentine, the rocky Alpine pastures of Switzerland, the fertile plains of France, and wherever cattle are raised. Cattle supply the hides which are one of the essential raw materials of the tanner and so of the belt maker, it is therefore necessary that the cattle industry should prosper if leather is to remain as universally useable a commodity as heretofore. Cattle are raised primarily for their labor value, their milk value and their meat value; the hide is very much of a by-product, and the matter of production of a hide specially suited to the requirements of the tanner is but an infinitesimal incentive to the cattle grower.

When steer hides sell at better than 26 cents a pound as they have this year, when as much as $40 per hide must be paid to secure a particular selection, it seems as though the hide, even if but a by-product, represents a sufficiently large percentage value to secure from the cattle grower an endeavor to produce a satisfactory hide. The tanner, however, has had a hard time to establish this point of view although, aided by governmental agencies whose interests have been different but objective similar, progress has been made.

Hide Imperfections

The particular evils of which the tanner has complained and for which the cattle raiser is responsible are three: barbed wire, brands and grubs. Barbed wire fences lead to scratches on the hair or grain side of the hide, which though they later heal yet constitute imperfections; branding destroys the hide fibre and makes so much of the hide as is touched by the branding iron absolutely worthless for purposes of belting manufacture; grubs are worst of all, for the reason that they do their damage in the very best part of the hide and oftentimes are so numerous that a hide affected by them gives the appearance of having been used as a target for a shot gun.

The first two evils are subject to individual correction; the last can be remedied only by concerted and widespread action. It is a question for governmental investigation and legislation. The investigation has been and is going on, but the efficient remedy is not yet, though progress is making. In one district in Denmark, for instance, where they can be reasonably autocratic, by making the presence of warbled cattle in herd punishable by fine, they reduced in six years' time the percentage of warbled cattle from 18 to 1. The above is mentioned for two reasons: first, to bespeak interest in any measures that may come to the reader's attention, calculated to improve the conditions mentioned, and second, to show you how uncontrollably imperfect is one of the tanners' raw materials.

Material Constitution of Hides

Apart from damages as cited there are material differences in hides—differences in texture, in plumpness, in uniformity, etc. It is generally true, for instance, that cattle in warm countries have thick hides and short hair, while in cold climates the reverse is true. The supply of first quality, extra heavy hides comes almost wholly from Southern Europe, and these being no longer obtainable as a consequence of the war we are hard put to it to produce extra heavy leather. Some cattle have hides which are very thick over the kidneys and thin over the shoulders; others show this difference much less markedly.

When the hide is removed, the way in which it is done is again a matter of keen interest to the tanner. Cuts in the hide made by the butcher when taking it off the animal lessen the value very materially. The take-off of hides from the large packing houses is usually excellent, the result of specific attention, carefully trained and expert labor. It is quite otherwise with the average country hides taken off by the town butcher, which despite the efforts of the Tanners' associations, are still a source of shame. The flaying is so bad that they rarely bring the price of a packer hide, and they represent a real and needless economic waste. Abroad, methods of so-called mechanical flaying have been introduced to avoid butcher cuts. By these methods the hide is pulled and hammered from the carcass and such hides usually command a premium, 50 cents a hide being an average figure at the Paris auctions.

Hide Preservation

What happens to the hide after its removal from the animal and before the tanner gets it, is again of importance. Hide, being essentially gelatine, readily spoils and must be preserved against decomposition. Two methods of preserving or curing hides are in vogue, viz.: drying and salting. The first is ordinarily too uncertain to permit of the use of hides cured in this way for belting, and practically all hides tanned for belting are what are known as green-salted hids.

If the belt manufacturer tans the leather which he makes into belting—and this is the ideal arrangement—he buys so far as possible green-salted hides, free from scratches, brands and grubs, short-haired, of as uniform thickness as obtainable and which have been skilfully taken off, so that they are free from butcher cuts; i.e., the manufacture of first quality belting begins with the purchase of first quality hides.

Initial Tanning Operations

Before being used for belting the hides must be tanned, i.e., so treated that they will not decompose or spoil and will remain flexible. There are various methods of tanning hides but whatever the method used, the first steps, usually spoken of as the beam house treatment, are essentially the same, namely: preliminary washing with water to remove dirt, and the salt or other material which may have been used to cure the hide; a cleaning of the flesh side to remove superfluous flesh, fat, etc., left on in the flaying—a soaking in milk of lime, or some other depilatory solution, to loosen the hair which is then pushed off by machine or with a dull two-handled knife; and a final washing to remove at least in part the unhairing chemical and to clean the hide. The quality of the finished leather depends in very large measure on the successful performance of these apparently simple operations. It is an old saying that leather is made in the beam house.

The conversion of the hide as above prepared into leather may be brought about through the use of any one of a variety of tanning materials, the peculiar characteristics of the finished leather being governed by the material used. Only a few of these materials will be mentioned and such only as have a special interest to the belt manufacturer.

One of the simplest and oldest methods of tanning is to cover the raw hide in the moist condition with grease and then continually manipulate it as it dries, thus working the grease into the inmost fibres of the hide and producing a grease-tanned leather. Grease-tanned leather has little more fullness or body than the original hide, but it is excep-

* Presented at the annual meeting of the Providence Association of Mechanical Engineers (A.S.M.E. Affiliation), September 22, 1915.

** Chemist, The Graton & Knight Mfg. Co., Worcester, Mass.

tionally strong. The so-called mechanical lace used for lacing together belting is tanned in this way.

Another method of tanning which has come down to us from olden times is to work into the hide a mixture of alum and salt. This gives a somewhat fuller leather than grease and is used before the grease treatment by some tanners of mechanical lace because of the fullness gained, but it is at the expense of the toughness and wearing qualities of the lace.

A modern tannage of somewhat similar nature is that with salts of chromium the hide being immersed in a solution of one of these salts. Chrome tanned leather is fuller than alum tanned and much more permanent. Water will seriously injure alum-tanned leather, causing it to revert nearly to the condition of raw hide and to become hard and cracky, whereas water has little or no effect on chrome leather. Chrome leather may even be immersed in boiling water for some little time without serious damage to the leather. Most of the so-called steam-proof belting is made from chrome-tanned leather.

Vegetable Material Tanning

By far the greatest percentage of heavy leather, and in particular that used for belting, is tanned with a tannin derived from some vegetable material. The procedure of the tanning process as early practised with vegetable materials was to spread the hides out flat in a vat with a relatively thick layer of the tanning material between the hides, the vat finally being filled with water. The water served as a medium of exchange, extracting the tannin from the vegetable material and giving it to the hide which absorbing it became tanned. The process was slow, often necessitating a year or two to effect the conversion of the hide into leather.

An improvement in the process was effected by substituting for the water a tan liquor obtained by leaching the tanning material in large tubs; i.e., extracting the soluble tannin by passing hot water through the ground raw material. Nowadays the use of the raw tanning material by the tanner is almost a thing of the past. He uses instead tanning extract prepared at plants usually located where the supply of raw material is abundant and which is a concentrated solution of tannin obtained by leaching the raw material with water as was formerly done at the tannery, and then evaporating away much of the water in a partial vacuum at low temperature and yielding as the commercial product ordinarily a thick brown liquid containing about 25 per cent. actual tannin.

Not merely does this supply the tanner with his tanning material in a form much more convenient for use, but it has the further decided advantage that the extract admits much more easily of analytical control and so makes possible the use of a determinate and uniform tanning agent. Since uniform product demands uniform raw material this is an improvement of no mean order.

Enumeration of Vegetable Tanning Materials

Not so long ago—in fact as recently as 1890—practically all the vegetable tanned heavy leather in this country was made with either hemlock or oak bark, or a mixture of the two. Now, while the old names, hemlock, oak and union, are still retained, it would be hard to find a tanner making leather with these materials alone. The present-day tanner uses not merely hemlock and oak, but chestnut wood, or valonia, or myrobalans, or mimosa, or quebracho, or wattle, or mallet, or algarobilla, etc., some twenty-five or thirty materials being commercially available.

With an increased range of materials came, of necessity, a study of the leather-making qualities of each. Marked differences appeared. For instance, the tannin of valonia was found to decompose rather rapidly, forming and depositing insoluble ellagic acid. The English tanner, earlier to use these materials, had discovered this by experience, and by using valonia and insuring the deposition of the ellagic acid in his leather, was making the solid English sole, water-proof and long-wearing, which earned him a reputation the world over. A myrobalan liquor was found to sour very rapidly, yielding eight times as much acid, for instance, as mimosa under the same conditions.

The leather-forming value of the materials varied; valonia would produce over 100 lb. of finished leather as against 75 for myrobalans, from the same weight of hide. Chestnut wood produced a leather of tensile strength over 3,000 lb. to the sq. in., while oak bark under similar conditions gave one of less than two. Here certainly was knowledge and opportunity the tanner could not neglect. Knowing what qualities he desired in his finished product, he could, by a careful selection of tanning materials, go far toward securing these qualities, this material making for fullness, that for strength, etc. The progressive tanner, who wanted to make the best belting leather could not afford to make oak belting with oak bark alone, and he did not, and his leather is the better in consequence.

Final Leather Constitution

The objection to practically all the tannages, aside from that with vegetable tannin, is that they do not make a plump, full, solid leather. The leather produced by them is tough, but thin and open. The original hide constitutes much the largest percentage of the finished product, only a small quantity of the tanning material remaining in the leather. This is in marked contrast to the vegetable tannage in which so much tannin and other matters is deposited in and on the fibres of the hide that the original hide constitutes less than 50 per cent. of the final leather.

Lack of firmness is a serious deficiency in a leather to be used for belting. Nevertheless, leathers made with some of the above materials have sufficiently valuable properties so that they have made considerable headway for belting even despite their failings. Chrome leather, for instance, can be produced in a comparatively short time. It will run practically unharmed in a temperature where vegetable tanned leather would revert to a brittle, formless mass. It can be made exceptionally flexible. It has a high coefficient of friction. Consequently belting from chrome leather has found a place for itself, which would be larger, were it not for the deficiencies resultant from the lightness of the tannage, the lack of solidity of the leather and the necessarily high cost because of the small leather-yield. A leather tanned with a combination of alum and gambier, the gambier being used to supply the deficiencies of the alum as a filling material, has likewise had some vogue. It is tough and pliable, and has given good service for high-speed work.

TRUING THE GRINDING WHEEL

By Howard W. Dunbar

GRINDING machine operators are sometimes puzzled because of their inability to accomplish a desired finish in grinding a piece of work, when a very little care in truing the wheel would bring about the results sought for.

It is not always our object in truing a wheel to sharpen it, as is ofttimes the belief of the operator. Primarily, we true the wheel to produce a perfectly round and true cylinder, for no work can be ground more accurate than the wheel is. The slightest imperfections in the wheel in roundness or trueness of surface will produce imperfections in the work being ground. Secondly, we true the wheel to produce on the face of the wheel the proper condition to accomplish the results desired in the finish. Oftentimes, contrary to the general belief, we dull the particles in the face of the wheel because we desire a certain finish.

The Diamond Condition.

It is not true that the diamond must have a sharp corner, or a sharp edge, or a sharp point in order to be of service in

wheel truing. On the contrary, a diamond after having been used for a short time is a better agent for truing than a new diamond, due principally to the fact that the sharp corners, small projections, etc., have been worn from the diamond, and it maintains for a greater length of time the same area of exposed surface presented to the wheel when truing.

It can be readily seen that if a small point on the diamond was presented to the wheel for truing, this point would soon be worn away, and a true cylinder could not be the result, since the diamond is a greater distance from the centre of the wheel at the finish of the truing than it was at the beginning. It is true that this amount is very small, but, in precision grinding, we are dealing with tenths of thousandths of an inch, which means the utmost care and attention to the smallest details.

Speed of the Diamond

The speed with which the diamond is moved across the face of the wheel is also a controlling factor in the finish. If the diamond is brought across the wheel rapidly, it, to a certain degree, trues a thread on the face of the wheel, and although this is not visible to the eye, it works havoc with the finish of the parts being ground, since, with this thread across the face of the wheel on a diagonal line, mottles are produced in the work, which give the appearance of a frosted surface.

The diamond should travel slowly enough across the face of the wheel to be sure that all the particles have been brought to a given height, and are an equal distance from the centre of the wheel. To do this right, light traversing cuts with a diamond must be taken so as not to break up the surface of the wheel, but to gradually wear the particles down so that they all have this uniform height.

For roughing work the surface of the wheel should be broken up; the particles should be sharp, and necessarily do not need to be as accurate as when finishing. In this event the diamond is passed across the face of the wheel a little more rapidly, and taking a deeper cut. This is called "breaking up" the surface of the wheel.

Wheel Grain

It is commonly believed by many that the degree of finish possible with a wheel is governed entirely by the size of grain used, so that for a fine, highly reflecting surface it is necessary to use a very fine wheel. This is not true. A high reflecting surface can be accomplished with a coarse wheel which will be economical in removing metal, by simply truing the face of the wheel to a perfect cylinder, and with all the particles of uniform height. It can be readily seen by analyzing this that the grain has little or no effect upon the finish, as the particles come in contact with the work in rapid succession one after the other, and simply plow a path through the work being ground equal to their height.

With such a multiplicity of cutting tools as are carried by the grinding wheel, it is impossible to conceive of a condition where any of these particles would be so separated as not to produce a round, true cylinder with a good surface, even though the grains be large, if they are all of equal height. Even a polishing operation can be accomplished with a comparatively coarse, hard wheel, if in truing, the particles are dulled, the corners rounded, where not even a grinding mark can be noticed in the work.

It is also essential in truing that plenty of water be allowed to flow on the diamond. As the diamond is extremely hard and the particles in the wheel are hard, heat is generated, which causes the wheel and diamond to wear away rapidly: by allowing the water to flow upon the wheel while truing, this heat is carried away by the water or compound, which allows us to accomplish the truing with a greater degree of accuracy and perfection.

Rigidity of Diamond Fixture

Of course, it goes without saying that the diamond must be clamped rigidly in the diamond tool holder on the table of the machine. Any movement of the attachment will create irregularities in the wheel surface.

In addition to being clamped rigidly, a line passing through the centre of the diamond and tool holder should point below the centre of the wheel so that the diamond will come in contact with the wheel on a slight angle, say, approximately 5°, which allows the diamond to wipe across the face of the wheel instead of digging into it, and prevents any chattering which would surely result if the diamond pointed above the centre of the wheel.

This is a very important feature in truing the wheel face to a perfect surface, and when troubles from chatters, diamond marks or feed lines result, the first thing to do is to see if the diamond is tight in the holder, tight in its setting and wipes across the face of the wheel rather than digging into it.—Grits and Grinds.

"Huxley" has said, "Science is nothing but trained and organized Common Sense, differing from the latter only as a veteran may from the raw recruit, and the methods differing from those of common sense, only as the guardsman's cut and thrust differ from the manner in which a savage wields a club."

HIGH-SPEED STEEL

IN view of the apparent scarcity of this class of steel for tools, a circular has been issued from the British Minister of Munitions in order to classify the requirements of the industries of the country, to advise economy, and to investigate measures of husbanding the scrap material to the best advantage. A series of questions has been drawn up and answers are invited from the engineering and manufacturing firms who use high-speed steel. The questions are as follows:

1—What are your monthly requirements of high-speed steel?

2—Have you any difficulty in obtaining your regular supplies?

3—What unused stock of high-speed steel have you at present on hand?

4—What stock of partly used tools and ends of bars which could be used for making tips and for other purposes?

5—Do you keep all high-speed scrap separate, so that it may be returned to the steel makers?

6—What saving have you made or do you expect to make by the use of tools with the tips only made of high-speed steel?

The replies are to be addressed to Small Tool Department, Director General of Munitions Supply, Armament Buildings, Whitehall, S.W.

BRITISH PURCHASING OFFICIALS IGNORANT OF CANADA'S RESOURCES

THE High Commissioner of Canada, Sir George Perley, chairman, at a lunch of the Canadian Exporters' Club, on Dec. 16, spoke of the need of educational work lying before Canadian exporters in Great Britain. The High Commissioner's Office had found the Imperial Ministers of State as conversant with the resources of Canada as he was himself, but the purchasing officials who placed Government contracts were in a state of blank ignorance. Superior organization had enabled United States exporters to take more than a fair share of Imperial contracts. It was only at the last moment that he had secured the recent timber contract for British Columbia which Oregon lumbermen were on the point of getting.

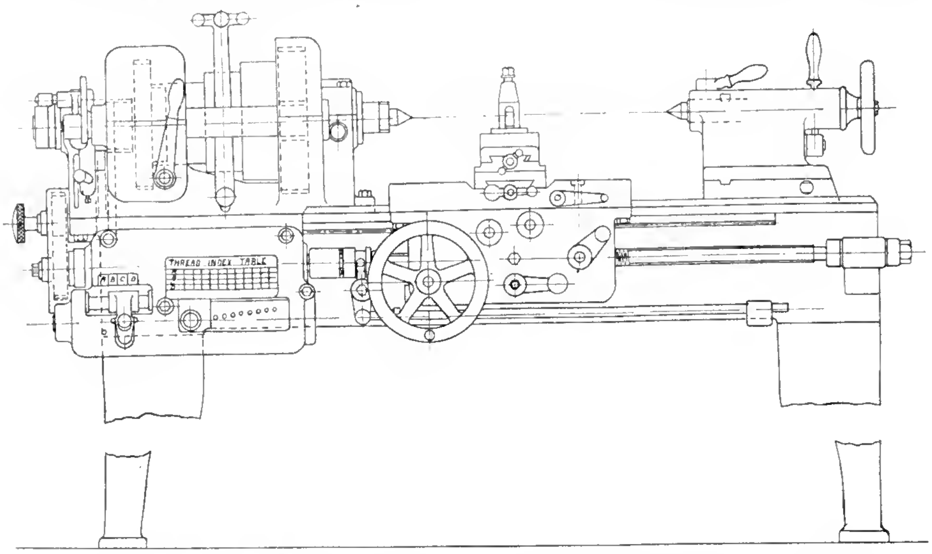
Secretary Armstrong, of the Canadian Exporters' Association, announced that the French had extended for Canada alone the date of entry at the Lyons Fair, which will take place next year instead of the Leipsic Fair, the period of grace given being a fortnight. Canadian entries will be received until January 15, and, thanks to the concession, Canada will have adequate representation.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

14-IN. ENGINE LATHE

THE 14-in. engine lathe shown in the accompanying line drawing has been designed and placed on the market by the Canada Machinery Corporation, Galt, Ont., to meet the demand for a high-grade tool possessing the accuracy and capabilities of a tool-room lathe, along with the simplicity of operation and rigidity of construction necessary to enable it to meet all manufacturing demands.



14-IN. SWING ENGINE LATHE, WITH TWO-SPEED DOUBLE-GEAR DRIVE.

This lathe swings 14 in. clear, over the ways, and $8\frac{1}{2}$ in. over the carriage, the bed being of conventional design, and ample proportions.

Several features are incorporated in the headstock which for a tool of this size impart more than passing interest to the design. A three-step cone for $2\frac{1}{2}$-in. belt in combination with a two-speed double gear provides nine spindle speeds. A departure from orthodox practice is the placing of the double gearing on the front of the headstock. The eccentric handle for throwing out the gear has a plunger stop for "in" and "out" positions which avoids the annoyance of gears jumping out when slacking off the chuck. The increased safety and convenience due to this location of gearing are perfectly obvious.

While the accessibility of the belt has been somewhat reduced, the provision of an efficient belt-shifting device more than overcomes this slight drawback.

A commendable feature of the headstock design is the type of feed reverse gear mechanism. The reverse locking handle is permanently attached to the screw and ample space for operation is provided which is in direct contrast to the majority of designs which require the use of a separate spanner wrench in such cramped quarters that use of the feed reverse gear is only resorted to when unavoidable.

A total of 44 feed changes in four groups of 11 feeds each is obtained through the gear box. The two controlling handles are arranged close to each other, enabling the operator to select the group and locate the required feed practically simultaneously. A compactly arranged quadrant has a specially designed device which provides for the cutting of coarse pitch threads, and enables special change gears to be introduced for odd threads.

The lead screw is splined so as to act as feed shaft when plain turning, the traverse motion of the carriage being obtained by rack and pinion.

The traversing handwheel is conveniently located at the left of the apron: the nut-clamp handle, feed reverse handle, and friction knobs for longitudinal and cross feeds being arranged with a view to the elimination of all uncertainty of action on the part of the operator.

A stop-rod which throws out a clutch on the lead shaft is fitted with adjustable stops for stopping the carriage feed at desired points.

The lathe as illustrated has a 5-ft. bed and takes 34 in. between centres, which are No. 4 Morse type.

The tailstock has a set-over adjustment on the base, and is clamped to the bed by eccentric and lever. Taper turning attachments are furnished when required.

Reverse is obtained by cross belt on countershaft, two 12-in. x $3\frac{1}{2}$-in. pulleys being provided running at 255 and 210 r.p.m.

Particular interest attaches to this lathe as owing to its general excellence in design and workmanship it was selected as the standard machine for lathe instruction at the Central Technical School, Toronto, the first contract calling for sixteen machines.

BIG VALVES FOR ELECTRIC POWER STATION

THE Nelson Valve Co. has recently completed a portion of their contract for supplying the valves which are to be used throughout the new station of the Philadelphia Electric Co., Philadelphia, Pa. Included in the installation will be valves of practically every kind, from the smallest brass gate and globe valves to huge 42-inch solid wedge steel gate valves, like that shown in the illustration. These enormous valves stand 14 feet high, and two of them weigh as much as an average size steam road roller. In all there are to be seven of these units.

When installed, they will be operated from central panels on the turbine operating floor, which is fifty feet above the condenser pit floor line. Operating conditions call for 80 pounds working pressure.

16-IN. MOTOR OPERATED SOLID WEDGE GATE VALVE.

The valves have a steel clutch for disengaging the motor, if it is desired to operate them by hand. The design is such , however , that hand operation drives the limit switch at all times, so that if the motor is thrown into opera-

42-IN. MOTOR OPERATED SOLID WEDGE GATE VALVE.

tion when the valve is partly open, the limit switch is in the proper position for starting the motor, and throws out the automatic circuit-breaker on the control panel at the proper closing point of the valve disc.

There is a lost motion device between the stem unit and the large operating gear for the purpose of giving a hammer blow effect to break the seat of the valve in the event of scale causing the wedge to adhere to the seat. The motor is designed, however, of ample torque to open the valve without this hammer blow effect.

The body, bonnet, yoke, cap and gland are of cast steel. Cast "monel" seat rings have been used in the body, and the bonnet has a "monel" pack-when-open bushing. The solid wedge is cast in one piece of "monel" metal, and the rolled "monel" stem is attached to the wedge by means of a flexible coupling. The stem unit is of manganese bronze.

One characteristic feature of the valves is the high condensing chamber and deep stuffing box. The condensing chamber being located between the stuffing box and the inside of the bonnet, is claimed to insure longer life of packing and safety in renewing packing.

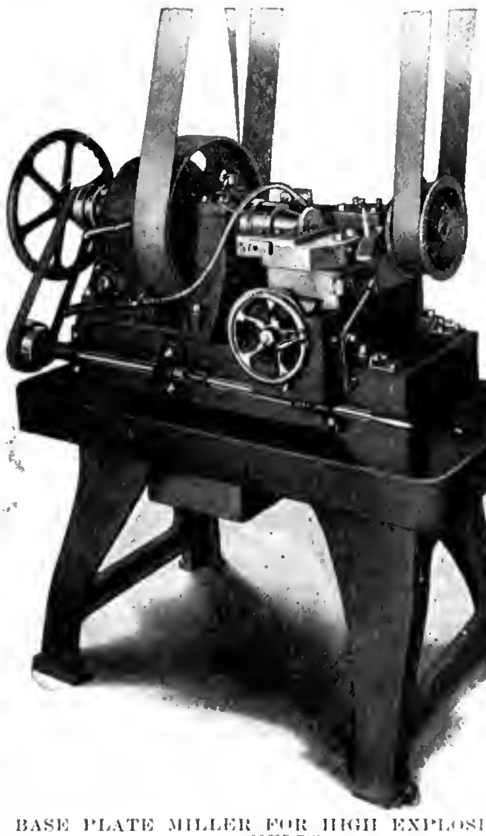
In addition to the 42-inch valves, seven 16-inch gate valves have been built and delivered. These valves are made for superheated steam of working pressure up to 250 pounds, and for a total temperature of 800 degrees F. Each valve has been tested to 800 pounds.

BASE PLATE MILLER FOR H. E. SHELLS

A NEW machine for milling base plates or plugs for high-explosive shells has been developed and is being built by Edwin J. Banfield, Toronto. This machine is designed for turning the outside diameter, finishing the face with the necessary camber and milling the threads, all at one chucking. It is of rigid and substantial construction and is driven direct from the line-shaft, no countershaft being necessary. The general design of the machine will be noted in the accompanying illustration.

On the bed, which is made of cast iron, there is mounted the headstock, and a saddle carrying the cross slide and tool holder. The headstock is movable and bolted to machined ways or slides, thus always keeping it in line when moving, being moved as is sometimes necessary if plugs of different thicknesses have to be machined. The headstock has a 3-in. hollow spindle with collet chuck and draw-back mechanism operated by a hand-wheel on the extreme left of the machine. A 16-in. x 4-in. pulley drives the spindle when machining the plug.

An important feature of the machine is a double jaw clutch mounted on the spindle and arranged so that in the first position it engages the main pulley with the spindle for machining the plug, and. in the second position, the spindle is re-



BASE PLATE MILLER FOR HIGH EXPLOSIVE SHELLS.

volved by a bronze worm and gear driven from an independent pulley at the back of the machine. The latter drive is used when milling the plug.

The fixture holding the tools and miller is mounted on a cross-slide on the saddle; the latter is movable and bolted to the bed. It is also adjustable so that any required camber can be obtained, the adjustment being made by means of four small set-screws. On the back of the cross-slide is fastened a bracket which carries a spindle holding the milling cutter, being driven by the pulley at the right-hand side of the machine. Extending from the bracket at the back is an arm carrying the chaser which engages with threads on outside of collet chuck. These threads have the same pitch as the threads on the plug, viz., fourteen per inch.

In operation, the square on the plug is gripped in the collet chuck. There are five tools in the tool post fixture which has the form of a right angle, and a roughing tool on the back section of cross-slide. This roughing tool turns the outside diameter and is brought into play by moving the cross-slide towards the operator. When this operation is completed, the cross-slide is moved back and the first tool roughs the face of the plug. This is followed immediately by a similar tool which finishes the face. The tool holder continues to travel forward and another tool faces the back of the plug for riveting purposes. This is followed by a tool which chamfers the corner.

The threads are milled at the next operation. The slide is moved back towards the operator until the milling cutter at the back is in position. A dog is slipped into position which ensures the chaser nut engaging with the threads on the outside of the collet chuck. The clutch on the main spindle is then thrown back, bringing the worm drive into gear and giving the spindle the slow motion necessary for milling the thread. As soon as the operation begins, the chaser moves along the collet chuck and regulates the travel of the milling cutter. When beginning the cut, the milling fixture is adjusted in position against a set-screw, and a hand lever is used to return the milling fixture to its original position at the end of the cut. The feed for the cross-slide for the initial operations is controlled by the horizontal shaft in front of the bed. A trip at the side throws the feed out at the end of the operation. The feed shaft is driven from a two-cone pulley on the main spindle. A tank is located under the bed for catching the cutting compound and a rotary pump driven from a worm gear at the back feeds the compound to the tools.

This machine is being used for turning and threading plugs for 18-pdr., 4.5-in., 60-pdr. and 6-in. high-explosive shells.

ELECTRIC AIR HEATER AND BLOWER

AN electric heat blower has been put on the market by the B. F. Sturtevant Co., of Galt, Ont., and Boston, Mass. This consists of a small motor-driven fan discharging air through heating coils placed in an aluminum casing. The forced circulation renders it possible to deliver a large volume of hot air in a short time. The apparatus is readily portable and can be used in the same way as electric cooking utensils in connection with any wiring system.

The set is made in five different sizes, and delivery of air is made at one, two or three temperatures, depending on the size. The fan outlet can be turned readily so as to discharge in any direction. The switch mounted on the base has different positions, and the temperature of the air delivered depends upon the position to which the switch is turned. Handle for carrying can be seen in illustration.

ELECTRIC AIR HEATER AND BLOWER.

This little heat blower is ideal for warming rooms in the fall or spring, or on a winter's morning to heat a chilly bath room, or bedroom after the windows have been closed. It is also used for drying hair, laundried articles, for blowing furnaces, and in the garage for heating and for melting ice off the car.

In industrial establishments the electric heat blower has a wide field of service, and may be used successfully for drying in dyeing and cleaning establishments, in photographic and blueprint rooms, in hair-dressing parlors, in rooms, boats or yachts for drying paint, in store windows for preventing frosted windows, in laboratories or doctors' offices. It is also used for heating larger rooms, small theatres, halls, schools, etc., which are only used occasionally.

SINGLE-SPINDLE SHELL BORING MACHINE

A MACHINE being used extensively for boring 6-in., 8-in., 10-in. and 12-in. shells when provided with an expansion boring bar, with outer support and cradle for holding the shells, is illustrated herewith. The drive to the spindle is by means of a large spur gear operated by a three-step cone, giving three speed changes varying approximately from 17 to 30 revolutions per minute. The work-table is fed along the bed by means of a rack and spiral gear, and it has three changes of geared feed, ranging from 0.010 to 0.050 inch per revolution of spindle; the maximum length of the feed is 32 inches. There is an automatic release to the feed, and the table can be operated by hand.

ELECTRIC AIR HEATER AND BLOWER.

The work table is 21 inches wide and 36 inches long over the working surface, and it is entirely surrounded by an oil channel. It has square locked bearings on the base, and side adjustment can be made by means of a taper shoe. The distance from the centre of the spindle to the top of the table is 8¼ inches. The spindle is 3½ inches in diameter; it has a broad driving slot and a thorough retaining bolt for holding the boring bars. The hole in the spindle is a No. 11 Brown & Sharpe taper. The equipment includes a pump with piping and attachments and a countershaft. This single spindle boring machine is a product of the Newton Machine Tool Works, Inc., Philadelphia, Pa.

SINGLE SPINDLE MACHINE FOR BORING 6 IN., 8 IN., 10 IN. AND 12 IN. SHELLS.

LOOSE PULLEY REPAIR

By L. P.

ONE of the most common minor worries of the engineer-in-charge in a factory is to get machine hands to pay attention to the lubricating of loose pulleys. Where a belt has often to run for an hour or two on the loose pulley, the bush soon gives trouble, even with careful attention.

In the works of which the writer has charge, a 100 h.p. suction gas engine and a 40 h.p. steam engine are both belted to the same line shaft, the steam engine belt is on the loose pulley for twelve hours a day. The pulley is 3 ft. 6 ins. diameter, 11 ins. face, 3 ins. bore, with a 10 in. double belt about 50 ft. long, and as the line shaft runs at 155 r.p.m., it is no wonder the pulley bush soon cuts out.

It is important that the belt be kept on the steam engine ready for a quick change over in case of emergency. After the bush of this pulley had cut out three times in three months, I had it bored out 1 in. larger than the shaft. It was then placed in position, and fitted with rollers made from ½ in. bright mild steel. These were left soft, and had no cage or separator. The collars which kept the pulley in position also kept the rollers in. This was done over twelve months ago. For a greater part of time the plant has worked seven days a week.

After such a gratifying result under such trying conditions, I have had no hesitation in serving other pulleys the same, and I shall not have any more pulleys fitted with bushes, the rollers being much cheaper in first cost, and should renewal be necessary this can be done in much less time than is the case with a bush, as it is unnecessary to take the pulley down.—Power User.

Total Crop Estimate of Three Provinces.—F. O. Fowler, secretary of the North-West Grain Dealers' Association, Winnipeg, Man., estimates the total crop of the three Prairie Provinces this year at 737,682,000 bushels, over 200,000,000 bushels greater than any previous crop. The estimate is divided as follows: Wheat, 307,230,000; oats, 389,000,000; barley, 39,202,000; flax, 2,250,000 bushels.

THE SEASON'S GREETINGS

THE editors of Canadian Machinery extend to its subscribers and correspondents the season's greetings, and take increased pleasure in doing so on this occasion, because of the many accessions to the ranks of each during the past twelve months. Since the establishment of this journal a decade ago, no one year has contributed so largely to our subscription lists numerically and as regards personnel, as has this Year of Grace 1915, and while aware that the percentage of firms, officials and operatives available to us are now on our books, and look forward eagerly to each issue as it comes from the press, we anticipate in the coming time to have the list practically all-embracing.

Our Annual Review Number comes from the press on December 30, bigger and brighter than ever, and brimful of Canada's progress, development and achievement in a world-memorable year. On January 6, 1916, the first number of a new volume will make its appearance, and, although good resolutions are more generally associated with the opening days of a new year, the closing days of an old year are, we believe, more conducive to their ultimate realization. Advantage should therefore be taken now by those still beyond the scope of our medium to take time by the forelock and enrol themselves so as to start with our Annual Review Number.

BRITISH MACHINE TOOL IMPORTS UNDER CONTROL

NOT a little excitement was aroused among machine builders in the United States and even in Canada when it became known that Great Britain had decided to control the importation of the products of such concerns in future. As is usual in similar circumstances, a good deal more was read into the proclamation instituting the enactment than it actually contained or was intended to convey. For the benefit of our readers, many of whom have doubtless heard nothing of the matter so far, we reproduce the cabled advice of the proclamation as well as the essence of follow-up cables concerning it.

Under date, December 2, the United States Embassy in London, advised the Department of Commerce, Washington, D.C., that "A Royal Proclamation of November 30, 1915, prohibits, after December 21, the importation into the United Kingdom of all machine tools and parts thereof, except small tools. A further exception is made in favor of machine tools, and parts thereof, imported under the license of the Board of Trade, and subject to the provisions and conditions of such license."

Receipt of subsequent cables in response to inquiries instituted by firms on this side, and apparently affected, elicited the information that the Board of Trade license will be available to all British importing firms established at least two years before the outbreak of war and doing business to the extent of $50,000 annually. Further, the firms so licensed must limit their profits to 18½ per cent.

In view of the foregoing, there is not even the semblance of a ban on the importation of Canadian and American machine tools into Britain, the effect being rather and altogether to ensure not only the uninterrupted receipt of the products of reputable machine tool builders on this side, but the protection of the good name of the latter which is equally important. It will also tend to centralize purchases, a convenience of no small moment.

A recent statement of Lloyd-George, Britain's Minister of Munitions, places the number of controlled factories at two thousand, and, the workers involved, at one million. It appears strange, yes surprising, that even while the scheme of control was in the early stages of development, no steps were taken to also control the necessarily imported requirements of the plants affected.

In the more or less headlong rush to equip, the unscrupulous dealer of course butted in, and while the meantime urgency practically prohibited challenging of his exorbitant prices for tools, or the extravagant claims made for their fitness for the required duty, operative experience seems to have laid bare the situation, and demanded some such step being taken as that embodied in the proclamation, etc., already quoted.

We may say that complete unanimity of opinion as to the wisdom of the action taken exists among all reputable builders of machine tools, both in Canada and the United States.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, Que., Dec. 20, 1915.—The closing days of the year 1915 find the commercial and industrial situation in a very satisfactory condition. The returns for export trade during the months of November and December will probably exceed those of any previous period in the history of the Dominion. The successful handling of a record grain crop has been one of the chief factors in the general business improvement.

Consumers of steel, whose needs are apparently urgent, are paying premiums of from $2 upwards per ton for early delivery of material. The pressure upon the steel producers, nevertheless, continues so great, that the placing of orders for early future shipment is almost impossible. With the probability, however, of no immediate action being taken as regards the manufacture of heavy guns in Canada, the market, before the spring, may show some indications of relief from the present strain.

Pig Iron

Even with the furnaces well filled up for the first quarter of the coming year and in many cases longer, inquiries for pig iron are still coming in. Local dealers report some little stir, but generally speaking, the market is quiet with quotations holding firm.

Steel

No relaxation is evident in the pressure lately prevailing in all lines of steel products. The mills are filled with orders so far in advance that listed quotations can only be taken as approximate. Buyers who wish delivery at an early period, may obtain same on payment of heavy premiums, but even this method is not always successful. While the mills are not taking on orders for specified delivery, they are endeavoring to arrange a schedule whereby the needs of their customers will be satisfactorily filled, without showing preference to anyone in particular.

Added to the inability of the producers to supply the demand, the shortage of cars is causing some inconvenience, delivery of coal to the mills being often delayed. Inquiries for billets, of late, have quieted down a little, owing likely to consumers being pretty well covered. Delay in placing further orders for shells is apparently having its effect upon this class of steel. The trade in bars, plates, and shapes, while quiet at present, shows some indications of early activity. Local prices remain unchanged.

Machine Tools and Supplies

Trade conditions throughout the machine tool industry continue active, and while the pressure along certain lines appears as great as a few weeks ago, there is a possibility that the opening months of the new year may find the intensified strain of the past half year somewhat relaxed.

Present indications point to the improbability of Canada partaking in the manufacture of heavy field guns, as the authorities believe that the delay in producing the required supply would be excessive. However, as many plants are rapidly being equipped for the production of the larger types of shells, the machine tool builders are kept busy supplying their requirements. Future necessities may yet call for the production of heavy ordnance.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

The improvement in the domestic demand for machine tools is quite noticeable, but the prospect of increased activity is hampered owing to delayed deliveries.

Inquiries for supplies continue to come in, and quotations on some lines have stiffened. High-speed steel and twist drills are in such demand that definite quotations are next to impossible.

Metals

The general condition of the various metals may be reported satisfactory. Copper, during the week has shown a slight advance, while tin is firm, but dull. Reports of the early closing of the Suez Canal will likely affect the delivery of future supplies. Lead has shown an advance after considerable dullness, but aluminum is on the decline.

Copper.—The market this week is stronger than of late, with dealers reporting brisk business. A firmer tone has been cabled from the London market, which has had its effect here. With the increased demand, quotations show an advance of $10 per ton. Lake copper is now quoted at $22 per hundred, and electrolytic is 21¾c per pound, while castings show an increase of ¼c per pound, being listed at 21¼c.

Tin.—The anticipated closing of the Suez Canal in the near future is expected to have some effect on this metal, as deliveries will be somewhat delayed, due to the longer sea passage. Local dealers report business quiet, but prices unchanged, at 45c per pound.

Spelter.—The situation shows little change from the previous week, and although inquiries are constantly coming in, local dealers are not being crowded. Foreign dealers report activity with advancing prices, but here there is no change. The market is firm at 21c per pound.

Lead.—This has been featureless for some time the demand appearing to be falling off. However, while dullness seems to prevail, the present prices show an advance of 1-10 cent per pound. This week's quotation is 6.85c per 100 pounds.

Antimony.—With plenty of antimony in sight for current consumption, the market is holding steady at last week's price of 42 cents per pound.

Aluminum.—The tension shown in this metal during the past few weeks seems to have reached its high-water mark, present prices being somewhat easier than a week ago. A decline of 2c per pound leaves the present price at 68 cents.

Old Material.—Business in the scrap metals during the past week has somewhat improved, and certain lines are showing strength. Considerable trading has been reported among dealers, and although many of the large mills are well covered for the coming quarter, they nevertheless are open to receive further supplies. No. 1 machine composition has been quite active during the past week and is stronger at our advance of $10 per ton. No. 1 wrought has also advanced, and is quoted this week at $10.50. Aluminum scrap is still in great demand and dealers are offering at the present time 32c per pound.

Toronto, Ont., Dec. 23.—There is little change of importance to note in the general industrial situation. Factories engaged upon war orders are busy, and the outlook in this respect continues favorable. The placing of these orders is now being done on a more systematic basis and as a result more business is coming to Canada. The complete trade returns for November have been made public by the Minister of Customs. The statement shows an increase of nearly 100 per cent. in domestic exports for November over the figures for the corresponding month last year.

The value of exports totals $92,000,000 made up in part of manufactured goods valued at $13,000,000, and minerals at

$6,500,000. The shell industry continues to create considerable interest and preparations for making the large calibre shells are being pushed ahead. The credit of $50,000,000 which the Dominion Government has established for financing war orders will meet, to a considerable extent, the financial requirements of the Imperial Munitions Board for some months to come. In order to facilitate the placing of additional shell contracts, the Hon. W. T. White, Minister of Finance, has suggested that Canadian manufacturers of munitions should accept as part payment, British exchequer bonds.

The steel market continues very firm, and prices have an upward tendency. A new list has been issued for wrought iron pipe, and iron bars have also advanced. New prices for cotton waste have been issued and another advance is expected in the near future. The machine tool business continues active and there is a better demand for lathes for the large shells. In the ingot metal market, copper and spelter have advanced and tin is developing greater strength. Lead, antimony and aluminum are unchanged.

Steel Market

The situation in the steel market continues much the same, the mills are operating at capacity and prices are holding very firm, with an advance on iron bars. Steel bars advanced to 2.75c recently and now iron bars are quoted at the same figure. With the mills employed principally on producing steel for munitions, deliveries on merchant bars are becoming more backward. Prices of wrought iron pipe have advanced. The new list went into effect on Dec. 14th. Prices of boiler plates and tubes are expected to advance early next year, but those on Pittsburgh bars, plates and shapes for this market are still withdrawn.

There is no improvement in the galvanized sheet situation, the market being demoralized with the continued advance in raw materials. Quotations are extremely irregular; some mills have withdrawn from the market while others are quoting on the basis of the cost of spelter. Prices in the selected quotations are pretty close to the market, but are liable to advance any time. The market for black sheets is very strong and prices have an upward tendency. No. 28 black sheets are quoted at 2.50c to 2.75c, and blue annealed 2.50c, Pittsburgh.

No new developments have to be noted in the American market. The mills are sold up for from four to six months and much of the business now being placed is for delivery at convenience of the mill. The export demand for finished iron and steel continues heavy but a railroad blockade in the East is holding up shipments and causing considerable delay and inconvenience. No important advances have been made during the week, it being the general opinion that values are quite high enough. The market, however, is very strong and the quotation of 1.70c, Pittsburgh, on bars, plates and shapes has become almost nominal. Prices of billets are unchanged, but are expected to advance as the scarcity is becoming more acute.

Pig Iron

Sales of Lake Superior ore have been very heavy at 75c advance over the 1915 quotations. The pig iron market is very strong and prices are very firm. Lake Superior charcoal iron has advanced to $19.25 per ton; other quotations are unchanged. "Hamilton" and "Victoria" brands are quoted at $24 per ton.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Messrs. S. Ruperti and Alexsieff, care Military Attache, Russian Embassy, Washington, D.C.

Coal and Coke

The coal and coke market is very strong, and prices have advanced on most grades. A big demand and shortage of labor has stiffened the market which may advance again in the near future. The new prices are given in the current market quotations.

Old Materials

The market for old materials is much firmer and improved business is reported. Steel melters are taking large tonnages of heavy melting steel, and prices are very firm. Scrap copper is also in good demand and quotations are slightly higher. Prices of other metals are unchanged.

Machine Tools

An important development in the machine tool market has been the publication of a proclamation in London prohibiting the importation into the United Kingdom of all machine tools and parts thereof, except small tools. An exception is made in favor of machine tools being imported under a Board of Trade license. The best opinion seems to be that the proclamation does not aim to cut off imports of machine tools, but to centralize purchases in the future and eliminate small dealers and speculators, thus protecting the market against inferior tools. The machine tool requirements in Great Britain are to a large extent satisfied, which should indirectly relieve the situation in Canada as regards deliveries. Locally, dealers report no change in the situation, and are actively employed figuring on equipment for machining the large-calibre shells. Suitable second-hand tools have become scarce and prices are higher.

Supplies

An advance in cotton and wool waste has been announced; the new list is given in the selected market quotations. Manufacturers advise that another advance will be made early in January. The increasing cost of raw materials has obliged the manufacturers to take this action. New and higher prices for bolts and nuts have been issued.

Metals

A slight advance in both copper and spelter are the two most important features to note this week. The copper market has been strong for some time and higher prices were expected. The spelter market is probably being manipulated. The Suez Canal scare has cropped up again, but there appears to be a probability that the canal will be closed for military reasons. In this event steamship routes will have to be adjusted and steamers will be obliged to use the Cape of Good Hope route. This arrangement will no doubt affect tin market on account of the delay involved to cargoes. The delay will not, however, be serious, as good stocks are available. The lead, antimony and aluminum markets are quiet and unchanged.

Copper.—The market is very strong, and is said to be controlled by the large producers. It is reported that the demand is as insistent as at any time during the last six weeks. The markets in London and New York are strong and higher. The local market has advanced ½c and Lake Copper is now quoted at 21¼c per pound.

Tin.—The London market is higher and prices are entirely nominal. There appears to be a possibility of the Suez Canal being closed, in which case shipments of tin would have to come round by the Cape. The delay entailed to shipments enroute would not necessarily be very serious, as available stocks are sufficient for immediate requirements. The market, however, may be affected temporarily and may go higher. Local

quotations are unchanged at 43c per pound.

Spelter.—The market is again unsettled and is apparently being manipulated. It is thought that there is a move on foot to depress prices. Local quotations are higher and nominal at 19c per pound.

Lead.—The London and New York markets are quiet and unchanged. The "Trust" price is 5.40c New York. Local quotations are unchanged at 7c per pound.

Antimony.—Recent arrivals of antimony in New York have caused the market to become easier. Business is quiet and quotations unchanged at 40c per pound.

Aluminum.—The market is easier but supplies continue to be scarce. Local quotations are unchanged at 60c per pound.

HIGHLY SATISFACTORY TRADE STATEMENT

WHAT is in many respects the most satisfactory statement of Canadian trade ever issued was made public on Dec. 16 by the Minister of Customs, Hon. J. S. Reid. The statement shows an increase of nearly 100 per cent. in domestic exports for November, as compared with the figures for November, 1914. The total under this head was $92,000,000. the imports for the month amounting in value to a little under half this sum, or $45,000,000.

The exports of $92,000,000 are made up principally of agricultural products, $54.000,000; manufactured goods, $13,000,000; animals and meats, $12,000,000; minerals, $6,500,000; lumber, etc., $4,500,000, and fisheries, $2,000,000. All these show a very substantial increase over the corresponding month for 1914. agricultural products jumping from $18,000,000 to $54,000,000. manufactured goods from $6,000,000 to $13,000,000, and animals, etc., from $8,000,000 to $12,000,000. The export of minerals is also exactly double that of November, 1914.

The feature of the imports totalling $45,000,000, is the large increase in the value of free goods imported during November last, these totalling $19,000,000. as against $12,000,000 for November, 1914. The total trade of Canada for November just ended, was $154,000,000, as against $126,000,000 for November, 1914.

For the eight months of the present fiscal year, Canadian trade totalled $863,000,000, as against $766,000,000 for the corresponding eight months of 1914.

Imports for the eight months of the present year were $298,000,000, a decrease of $20,000,000 for the corresponding period of 1914.

The domestic exports for the eight months of the present fiscal year were $419,000,000, as against $269,000,000 for the same period last year.

CANADIAN COMMERCIAL INTELLIGENCE SERVICE

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

Ottawa. R. Grigg, Commissioner of Commerce.

CANADIAN TRADE COMMISSIONERS.

Argentine Republic.
H. R. Poussette, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

Australasia.
D. H. Ross, Stock Exchange Building, Melbourne, Cable address, Canadian.

British West Indies.
E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

China.
J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Canecoma.

Cuba.
Acting Trade Commissioner, Lonja del Comercio, Apartado 1290, Havana. Cable address, Cantraecm.

France.
Phillipe Roy, Commissioner General, 17 and 19 Boulevard les Capucines, Paris. Cable address, Stadacona.

Japan.
G. B. Johnson, P.O. Box 109, Yokohama. Cable address, Canadian.

Holland.
Acting Trade Commissioner Zuidblaak, 26, Rotterdam. Cable address, Watermill.

Newfoundland.
W. B. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

New Zealand.
W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

South Africa.
W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

United Kingdom.
E. de B. Arnaud, Sun Building, Clare Street, Bristol. Cable address, Canadian.
J. E. Ray, Central House, Birmingham. Cable address, Canadian.
Acting Trade Commissioner, North British Building, East Parade, Leeds. Cable address, Canadian.
F. A. C. Bickerdike, Canada Chambers, 36 Spring Gardens, Manchester. Cable address, Cantracom.
J. Forsythe Smith, Fruit Trade Commissioner, Canada Chambers, 36 Spring Gardens, Manchester.
J. T. Lithgow, 87 Union Street, Glasgow, Scotland. Cable address, Contracom.
Harrison Watson, 73 Basinghall Street, London, E.C., England. Cable address, Sleighing, London.

SPECIAL TRADE COMMISSIONER—LUMBER.

H. R. McMillan, visiting Europe, Africa, Australasia and the Orient.

CANADIAN COMMERCIAL AGENTS.

British West Indies.
Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian.
R. H. Curry, Nassau, Bahamas.

Norway and Denmark.
C. E. Sontum, Grubbeged No. 4, Christiana, Norway. Cable address, Sontums.

South Africa.

United Kingdom.
W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Hamilton, Ont.—The Tallman Brass Co. are building an addition to their plant.

Quebec, Que.—The Shawinigan Electric Power Co. will build a transformer station here.

Woodstock, Ont.—William Baird will build an addition to his machine shop on Dundas Street.

Vancouver, B.C.—The C. P. R. propose installing a 50-ton electric crane on their wharf here.

Welland, Ont.—The Canada Forge Co. will build an addition to their forging plant at a cost of $25,000.

Montreal, Que.—A large extension will be made to the local plant of the Steel Company of Canada. The cost will be approximately $24,000.

Dartmouth, N.S.—The Williston Steel & Foundry Co., of Halifax, will build a steel plant here at a cost of about $16,000.

Chatham, Ont.—It is authoritatively reported that the Imperial Oil Company intends building a refinery in Western Canada, supplied by a pipe line from Wyoming fields.

Transcona, Man. — The Transcona Shell Co. are installing special machinery in the railway shops here for making munitions. Sir Herbert Holt, of Montreal, is interested in the company.

London, Ont.—An addition, costing $40,000, will be made to the London Gas Engine Co. plant here. Some time ago the buildings and machinery were disposed of by W. H. Braddon to W. H. Heard, of the Spramotor Co.

Halifax, N.S.—The Halifax Tramway Co. will make large extensions to their power installation, costing about $500,000. The additions include a complete gas plant having a capacity of 600,000 cubic feet, with provision for further enlargement. A new machine shop will also be built. 146 ft. by 150 ft.

Hamilton, Ont.—The Canadian Cartridge Co. have purchased a four-acre site, and will immediately begin work on the construction of a large addition to their factory. The extension will include a brass foundry and a plant for rolling brass sheets. Blanks for cartridge cases will also be made. The company, of which F. W. Baillie is manager, plans to spend over $250,000 on the new

Municipal

Guelph, Ont.—The hydro-radial bylaw will be submitted to the ratepayers on January 3.

Hull, Que.—The city council are contemplating extensions to the lighting system, estimated to cost $20,000.

CANADIAN PURCHASES FOR FRENCH WAR OFFICE

Philippe Roy, General Commissioner for Canada, Paris, advises the Department of Trade and Commerce, Ottawa, that an order has been issued by the War Department of the French Government to the effect that all purchases made by the Supply Branch in Canada will pass through the Hudson Bay Co. Canadian producers should therefore submit their future offers through the office of that company at Montreal. It is further stated in Mr. Roy's communication that Canadian lumber, steel and meat will find in France an important market for years to come, but it is necessary that Canadian firms should have in Paris representatives entrusted with the necessary authority, especially if it is desired to secure Government contracts.

Port Elgin, Ont.—The Village Council will submit a by-law to authorize the installation of a hydro-electric system.

Cobden, Ont.—The ratepayers vote on a by-law on Dec. 27 to raise $20,000 for the construction of a plant for the generation and distribution of power.

Melfort, Sask.—The town is considering the purchase of a 240-h.p. Diesel oil engine for its power house at a cost of $17,000.

Hamilton, Ont.—Chief Ten Eyck has submitted plans and specifications for a new motor truck for the fire department. Tenders will be called later.

Unionville, Ont.—The town council contemplate improvements to the waterworks system to cost about $12,000. E. A. James of Toronto is the consulting engineer.

Tweed, Ont.—The town council contemplate the construction of a waterworks system at an estimated cost of $25,000. Kerry and Chaee, Ltd., Toronto, are the engineers.

Glace Bay, N.S.—Plans are being prepared for the installation of a pumping unit, estimated to cost between $5,000 and $10,000. A. McKinnon is town engineer.

St. Thomas, Ont.—The Village of West Lorne voted last Monday on the introduction of hydro for lighting and power. The by-law was carried by a majority of 100.

Alliston, Ont.—A by-law will be voted on by the ratepayers on Jan. 4 to sanction certain privileges to the Alliston Electric Light Co., to erect transmission lines for lighting purposes.

Toronto, Ont.—The Board of Control have requested the Hydro-Electric Commission to enter into negotiations for the purchase of the Metropolitan division of the Toronto & York Radial Railway Co.

Cornwall, Ont.—A by-law will be voted on by the ratepayers on Jan. 3 to raise the sum of $25,000 for the purpose of erecting an addition to the pumping station and installing additional machinery.

Warwick, Que.—The Town Council are considering the construction of a light and power system at an approximate cost of $10,000, and are negotiating with the Arthabasca Water & Power Co. for a supply of power.

Listowel, Ont.—A by-law will be submitted to the ratepayers on January 3rd to authorize the loan of $12,000 to a company for the erection of a boot and shoe factory. The company consists of H. B. Morphy, F. W. Hay, A. H. Hawkins and J. S. McGee, all of Listowel.

General Industrial

St. Catharines, Ont.—A chemical works is being established here to manufacture potash.

Hamilton, Ont.—Negotiations are now under way with a company who propose establishing a factory here.

Fergus, Ont.—A by-law to loan the Superior Barn Equipment Co. $10,000 for the establishment of a factory will be submitted to the ratepayers.

Montreal, Que.—The premises of the Boston Blacking Co., 23 Cabot street, Cote St. Paul, was destroyed by fire on Dec. 11, the damage being estimated at $5,000. Spontaneous combustion is believed to have been the cause.

Kincardine, Ont.—A by-law to grant tax exemption for a period of ten years to the Ontario People's Salt & Soda Co. will be submitted at the January elections. The company propose making additions to their plant, estimated to cost $10,000.

St. Catharines, Ont.—A new factory is to be started in St. Catharines with potash as its output. The company, which is known as Chemical Refinery, Ltd., will manufacture potash from refuse, which will be used as a cheap land fertilizer. Construction work has already been started. A by-law to grant partial exemption will be voted upon by the ratepayers in January.

Personal

David Arthur Law, superintendent of the Waterworks Department, Prince Albert, Sask., died in Winnipeg, Man., on Dec. 9, aged 46.

Colonel David Carnegie, of the Imperial Munitions Board, has left for New York, whence he sails to spend six weeks or two months in England.

Frank E. Watkins, formerly associated with the Canadian Fairbanks-Morse Co., Ltd., Toronto, Ont., has been made works manager of the East Jersey Pipe Corporation, Paterson, N.J.

T. R. Deacon, president of the Manitoba Bridge & Iron Works, Winnipeg, and **J. G. Sullivan**, chief engineer of the C. P. R. Western Lines, were present at the breaking through of the heading of the five-mile tunnel under Rodgers Pass on December 13.

General Alex. Bertram, deputy chairman of the Imperial Munitions Board, has left Ottawa for the South for a vacation. General Bertram is feeling the effects of the prolonged strain of his work since the Shell Committee, of which he was head, was created, and has taken his first vacation since that time.

William A. Conner, vice-president of the Standard Underground Cable Co. of Canada, Ltd., Hamilton, Ont., died Dec. 6. The deceased, who was a resident of Plainfield, N.J., has been a director of the above company for the past ten years and first vice-president since 1909. He planned and constructed the Hamilton works.

Trade Gossip

The Dominion Chain Co. have increased their capital stock to $500,000.

The Canadian Car & Foundry Co., Montreal, has recently secured a contract from the Union Government of South Africa for two steel, underframe flat cars.

Windsor, Ont.—Machinery is being installed in the new Windsor Ice & Coal Co. building, at McDougall and Shepherd streets, and the place will be ready for occupancy by February 1. It will be used as a cold storage plant. The cost of the building, with machinery, is estimated at $30,000.

Lachine Canal Tonnage.—Final figures regarding the Lachine Canal navigation season show that 41,352,876 bushels of grain were brought down this year, as against 67,343,952 bushels in 1914, a decrease of 26,991,076 bushels. The total number of vessels which used the canal was 590, as against 615 last year, but their total combined tonnage this year amounted to 249,050, an increase of 19,795 tons.

Ford Motor Co. Increases Capital.—The stockholders of the Ford Motor Co., Ltd., of Canada, at a meeting held at Ford, Ont., on Dec. 14, ratified the increasing of the capital of the company from $1,000,000 to $10,000,000 and the distribution of 100 per cent. dividend. The Canadian Ford Co. was incorporated in 1904 with $125,000 capital. The charter was under the laws of the Province of Ontario. This charter was afterwards cancelled and a charter obtained under the laws of the Dominion of Canada, with a capital of $1,000,000. The stockholders at the time received a stock dividend of eight to one.

N. S. Engineers Meet.—The ninth annual meeting of the N. S. Society of Engineers held at Halifax, N.S., recently, elected the following officers: President, J. L. Allan; first vice-president, W. S. Ayers; second vice-president, A. J. Barnes; secretary-treasurer, D. McD. Campbell. Councils: Halifax, Guysboro, and Hants, J. W. Roland and P. A. Freeman; Cape Breton, G. D. McDougall, C. M. Odell; Antigonish, Pictou, Colchester and Cumberland, R. E. Chambers, A. J. Robb; Kings, Annapolis, Digby, Yarmouth, Shelburne, Lunenburg and Queens, James McGregor, F. H. Sexton. Auditors: J. H. Winfield, L. H. Weaton.

Rogers Pass Tunnel.—The final charge was exploded on December 19 in the heart of Mount Macdonald, opening a passage between the east and west headings in the C. P. R. tunnel now being drilled through this mountain. The ceremony was performed two and a half miles from either exit, six thousand feet below the surface. The construction of Rogers Pass Tunnel is the greatest engineering feat of the kind on the continent. The tunnel when completed late in 1916 will be 26,400 feet long, and with approaches an additional nine miles. The width is 29 feet and height 21. There is a double-track. It saves an elevation of 552 feet, reduces the track length 4.3 miles, eliminates 2,400 degrees of curvature and four and a half miles of snowsheds. The maximum grade in the tunnel is $95.100.

Tenders

St. Hyacinthe, Que.—Tenders will be received up to January 11 for a mechanical filter plant. Plans and specifications may be obtained at the office of Hector Cadieux, city engineer.

Winnipeg, Man.—Tenders will be received up to Monday, December 27, 1915, for the supply on one saddle tank locomotive to the Greater Winnipeg Water Commission. Specifications and form of tender may be obtained and contract may be inspected at the offices of the district, 901 Boyd Building, Winnipeg, Man.

Halifax, N. S.—Tenders will be received by the Governor of the Province of Macao, up to till January 8, 1916, for the supply of a steel, self-propelling dredge for the use of the Macao Harbor Works. Full particulars may be obtained at the office of Fred H. Oxley, Consul for Portugal, Keith Bldg., Halifax, N.S.

Winnipeg, Man.—Tenders, addressed to the undersigned, will be received up to Wednesday, Dec. 29, 1915, for the supply of one steam operated dragline excavator. Specifications and form of tender may be obtained at the office of the Greater Winnipeg Water District, S. H. Reynolds, Chairman of Commissioners, 901 Boyd Building, Winnipeg.

Winnipeg, Man. — Tenders addressed to the undersigned will be received up to Wednesday, December 29, 1915, for the supply of twenty twenty-yard automatic air-dump cars. Specifications and form of tender may be obtained and form of contract may be inspected at the office of the district, S. H. Reynolds, Chairman of the Greater Winnipeg Water Commissioners, 901 Boyd Building, Winnipeg, Man.

Annual Review Number

Retrospect and Prospect

"Ring Out the Old, Ring in the New,
Ring Out the False, Ring in the True,
The Year is Dying, Let It Go."

INDUSTRIAL prosperity has been a marked feature of the past year, and although unavoidably of a grim type, its immediate effect has been such as to place Canadian business and commercial enterprises on a pedestal of achievement hitherto considered beyond their grasp. The manufacture of munitions of war has demonstrated our readiness to cope with an emergency, as well as our resourcefulness, ingenuity and operative skill. Our metal-working plant capacities have been increased twofold, and, what is perhaps of greater importance, we have been enabled to break away from our traditional conservatism as regards manufacturing a greater variety product and catering to wider scope markets. Shell making on its own account and the activity developed in the machine tool and steel industries have so overshadowed everything else in volume and value output that on this occasion their combination feature rightly claims first consideration.

Shell Manufacture

In our 1914 Annual Review Number a brief descriptive article appeared relative to shrapnel shells, their manufacture in Canada having been then little more than started, although the experimental stage had been satisfactorily passed by most of the metal-working plants undertaking the work. We chose at that time as a title for the article: "The Manufacture of Shells, an Impromptu Canadian Industry," but those of us who have been in close touch with machine tool and machine shop activities during the past twelve months will frankly admit that the impromptu feature has disappeared and that munitions production has for a long period, is now and may continue to be for several months one of our staple industries.

On that occasion we indicated that contracts for the manufacture of shells in Canada would be distributed by a specially-appointed Shell Committee, and laid special emphasis on the fact that in placing contracts, arranging for the finished and semi-finished parts, collecting, assembling and inspecting these in detail and as the completed shell, the difficulties to be encountered and the work involved were such as the man in the street was quite unable to appreciate. Many seemingly insurmountable obstacles were met and successfully overcome, with the result that for over a year now shell production has been creditably achieved in Canada over a wide area and through the medium of metal-working plants, widely diverse in capacity and as regards peace-time commodity.

Shell Committee Achievement

By the engineering skill, expert knowledge and untiring energy and disinterested activities of Brig.-Gen. Bertram, Hon. Col. Thomas Cantley, and Hon. Col. David Carnegie, we have not only placed ourselves in a more favorable position to compete successfully in the world markets against older-established manufacturing countries, but have, in addition, given substantial and effective aid to our Empire in its hour of trial. Detractors of the work of the Shell Committee, as was to be expected, have neither been few, nor sparing in their criticism. Justification of the committee's work is, however, superfluous in view of the results achieved and the widespread benefits derived by our citizens generally.

The abnormal industrial activity arising from shell manufacture has of necessity affected more or less every other forms of enterprise, some, of course, adversely, for the time being at least. Taken as a whole, however, and not losing sight of our record Western crop, it goes without saying that our lot has been far above the average during the year 1915, and that those—either individuals, communities, manufacturers, builders, transportation and public utility corporations, who have not yet participated in the prosperity enjoyed by their confreres, have every reason to anticipate its early opportunity.

RESOURCES CONSERVATION NECESSARY

The Canadian people would be wise to take advantage of this spell of prosperity not to indulge in extravagance, nor to launch out into new schemes of development which are not absolutely necessary or immediately reproductive, but to conserve their resources in every way possible. The British people are being hard pressed. The burden of taxation is huge. They will have to economize in every way possible. The help that is of the utmost value to them is the help the Dominions can give by, if possible, extending their credit. The power of the Dominion to do that is directly determined by the productive energy and economy of its own citizens.—Hon. R. H. Brand.

Railroads—Steam and Electric

As might naturally be expected, railroad extension, development and betterment have been much halted and curtailed during the year. The double circumstance of the pronounced business depression and the poor Western crop of 1914 were in themselves sufficient as deterrents to even a moderate degree of enterprise by either steam or electric railroad corporations. Attention has been devoted for the most part to upkeep of equipment and permanent way, and to the improvement of terminal facilities. The three most outstanding features in the year's activities of our three principal railroads are those of the equipment and opening of the Grand Trunk Pacific drydock and ship-repairing plant at Prince Rupert, B.C., the railroads Western terminal; the successful piercing of the Rogers Pass Tunnel, on Mount MacDonald, by the C.P.R.; and the progress towards completion of the tunnel through Mount Royal, Montreal, by the C.N.R. Regarding the

Rogers Pass Tunnel in the Rockies, facts of interest are those that the tunnel will be double-tracked, and 26,400 ft. long; that an elevation of 552 ft. and a track length of 4.3 miles are saved, while 2,400 degrees of curvature and 4½ miles of snow sheds are eliminated. The tunnel is expected to be wholly complete late in 1916.

Skilled Labor Scarcity

Due to recruiting for Canada's Overseas Contingents, skilled labor for munitions and general work shows an abnormal scarcity. The "Mechanics Wanted" columns of the daily and other press mediums continue to bear ample evidence of the acuteness of the situation, the requirements being for men experienced in the operation of machine tools for the most part. Several hundred of our mechanics have gone to Great Britain on contract for munitions work, but the measure of success of such a proceeding is not too clearly evident. Certain it is that by far the largest percentage of the men who have gone from our shores for the above purpose would have done equally well, if not better, in numerous munitions factories in Eastern Canada. Besides, the Empire aid would have been equally effective, and perhaps a great deal more so. A pleasing feature of the labor situation during the year has been the absence of strikes, and, therefore, the absence of bitterness between employer and employee.

New Union Station, Toronto

After many promises to proceed with this undertaking, and a prodigality of rumors as to dates on which the project would really be negotiated in earnest, the interested parties have at last taken definite action, and, although in the nature of things, having regard to the varied considerations entering into the project, and particularly those arising from the effects of the war in the matter of financial requirements, progress may be slow and effort somewhat curtailed, continuous work on the structure will be maintained to completion. While the need is great for a new Union Station in our Queen City, there are other directions in which the need is still greater, and which may not yield place to any other.

Financial

Our banks, like our manufacturers and our farmers, have had a good year, and, being interdependent, it could hardly have been otherwise. Individual, community, and national expenditures have for the most part been judiciously curtailed, the result being that the savings of our people have increased at an abnormal, although commendable, rate on bank deposit account, and in consequence have been withheld from speculative and other equally uncertain risks. In the development of the shell industry, our banks have borne their share, and arrangements are now in progress, we understand, to still further appropriate their aid.

Our Crop Records

This being referred to incidentally in a number of other sections of our review, it is only necessary to add here that, in addition to the provision of increased acreage on the part of our farmers, Providence was not only kind, but magnanimous. The 1915 crop has put prosperity in the West equivalent to that we are enjoying in the East, and it goes without saying that soberly, determined disposition of the revenue accruing from the earth's yield, will be the rule rather than the exception, as was the case in big crop years not over remote. Manufacturing in the East is sure to benefit greatly from the success of Western farming in 1915.

Gun Making in Canada

In the fall of the present year inquiry was made and investigation undertaken with a view to determining the suitability and adaptability of Canadian metal-working plants to the manufacture of ordnance to British Government specifications. A representative committee was appointed and in addition two experts in the persons of Sir Frederick Donaldson and General Mahan from the British War Office made a tour of inspection of our engineering establishments which in equipment and resources met most nearly the special requirements. Hopes were entertained that even on a small scale the manufacture of ordnance would be added to the list of our industries, but intimation received after the presentation of the expert report indicated that while we no doubt could successfully overcome the initial difficulties and make satisfactory headway in production, the time that must necessarily elapse before the latter was reached would most probably make our effort of questionable value during the present war.

In a sense it is perhaps just as well that the ordnance making proposition is meantime dropped, for being a highly skilled enterprise and much limited in its scope, neither the number of employees nor the wide circulation of money arising from orders placed compare in the least with the like considerations in shell manufacture. We have mastered the shell business, and its influence in every respect is broad and comprehensive; if we get all that is available, which we have a right to expect, then both the British Government and we ourselves will profit more than if we had gone into ordnance making as well.

New Welland Ship Canal

Work on this undertaking is proceeding satisfactorily, the importance of its completion within the anticipated time, because of the transportation advantages to be realized, nullifying as far as possible any restriction of expenditure that the war might tend to create. Unlike its big brother, the projected Georgian Bay Ship Canal, the Welland Canal is a proven utility, and will continue to enhance its reputation as such with the development of each succeeding year's Canadian agricultural and manufacturing enterprise. As regards the proposed Georgian Bay Canal, we are inclined to think that the war has made it more of a dream than ever before. In any case, at least a decade will pass before its sponsors evidence further activity on its behalf.

Port and Harbor Development

Port, harbor and waterway development, although not prosecuted on the like extensive scale to which we have been accustomed in recent years, has not wholly been halted. The Department of Marine and Fisheries and the various harbor commissions at our principal lake and ocean ports have applied themselves during the year to not only the maintenance of facilities already installed, but to their improvement in many directions, and to their addition in a host of others. Port records in some instances are not likely to make as good a showing for 1915 as for some immediately preceding seasons of navigation, due entirely to the disorganization of steamship services through the requisitioning of so many vessels from the fleets of leading shipping corporations, for trooping and hospital purposes, etc.

1915 Season of Navigation

The 1915 season of navigation now closed on Canada's inland waters has been, taken as a whole, generally satisfactory. The transfer of many lake craft early in and during the year to ocean service did much to offset the lean and opening months in so far as revenue production was concerned, and the successful transportation of a record percentage of a record crop in the period from September 1 to late in December, removed all doubt as to the revenue assuming substantial proportions.

On our lakes and rivers during 1915 there has been a pleasing absence of disaster and tragedy, casualties being for the most part light relative to both men and ships. Stormy, and recently quite wintry weather has prevailed on numerous occasions, but, thanks largely to beforehand advice being transmitted to the various ports and signal stations by the Weather Bureau, the necessary steps were taken by vesselmen to remain in or procure shelter.

The year 1915 in a world sense, however, has borne on its bosom a weight of marine tragedies and disasters. Storm

and tempest in their wildest and angriest moods, or in their most comprehensive operation scope have but a mean record to their credit compared to that established by man's ingenuity and artifices in the prosecution of this world war. On sea as well as on land a myriad masterpieces of man's brain and brawn have been destroyed and annihilated, and, no less true is it, that of men themselves—brave and unflinching, thousands have found a watery grave in one section or another of the Seven Seas.

Canadian Shipbuilding

A feature of the past year has been the transfer of many of our lake craft to ocean and ocean coasting service, this having become necessary because of the scarcity of "bottoms" in these spheres, the regular traders being employed for the most part on military and naval transport work for the Imperial Government. On a previous occasion we hinted at the possibility of many of our lake craft remaining at sea indefinitely. On aeount of the remunerative freight rates, and in view of the fact that transports and merchant vessels as well as battleships, in totals almost shocking, rest on oceans' bottoms, there will be numerous orders that even boom years in shipbuilding will find hard to fill, at least as promptly as will be the need. Again, many of our lake vessels will undoubtedly find the old Atlantic quite too strenuous, especially in its angry winter moods. Some of the craft have already succumbed, and in the nature of things, no matter how optimistic one may be and how high may be our opinions of the staunchness and fitness of our lake freighters for ocean service, it is quite inevitable that several more will be called upon to yield to the elements.

In years past, both recent and fairly remote, we have gone to the British Isles for our lake carriers—those of "canal size" particularly. Our vessel stock is becoming quite noticeably depleted, and, as stated above, is sure to maintain the tendency in that direction. We will, therefore, wake up to the fact, probably when it is too late, that Canada's trade and commerce has so developed, and is being so neglected, that she needs more ships. Under such circumstances, turning to Great Britain to build for us will be out of the question, for her own merchant marine will be in process of replenishing and will, of course, get first call.

Shipbuilding in Canada needs fostering; it has always needed it, although little was forthcoming. Canada needs merchant ships—lake, coastwise and ocean types—and by grasping the opportunity to place orders for their vessel requirements now, our shipping corporations would be directly helping themselves and incidentally establishing the shipbuilding industry of this Dominion on a sound and prosperous basis.

Iron, Steel and Metals

Iron, steel and metals during the year are dealt with at considerable length in other sections of this issue; it is, therefore, unnecessary to do more than refer to them here briefly. The abnormal demand for steel—finished and semi-finished—has drawn attention to the national importance of the industry, both as a supplier of our myriad domestic needs and as a factor in the development of a much to be desired export trade, and the most gratifying feature of the situation is to be found in the responsible appreciation being displayed and the earnestness of effort being put forth to consummate the above-mentioned dual achievement.

Technical Education

In matters educational, and more specifically that bearing in the technical direction, there falls to be recorded the completion and opening for business of the New Central Technical School at Toronto. A very full illustrated description of the Institution appears in this issue, from which there will be gathered that from every viewpoint it occupies a place of first prominence among similar establishments the world over. Considerable impetus, as a result, has been given the movement towards technical training all through the Dominion, and particularly in the larger industrial centres. Great things are of course looked for from this magnificent and up-to-the-minute school, and if these materialize, we may expect to find the scope of technical education in Canada increasing by leaps and bounds with each unfolding year.

New Quebec Bridge

Notwithstanding the general business upset due to the war and the widespread organization of our factories for munitions manufacture, work has proceeded at a most satisfactory pace on the erection of the new Quebec bridge. The illustrations accompanying the article appearing in another section of this issue indicate very clearly the progress made during 1915, and more particularly so if comparison be made between pictures of the structure when operations ceased for the winter of 1914, and the present one. In spite of the stupendous nature of the task, both in the shop and in the field, the builders are meeting every problem and contingency successfully, and we anticipate that when we chronicle progress made at the end of 1916, the achievement will be such as to warrant still further appreciation of the work of Canadian engineers.

Power Development

The past year, so far as the establishment of power generating plants is concerned, has been a lean one, a circumstance almost wholly traceable to the European War. Progress in the development and perfecting of new equipment has in consequence also been less marked. The demand for munitions of war from our factories has had but an indirect influence in stimulating business in power plant machinery and supplies, although the latter feature may in many lines be said to be well ahead of normal or peace times.

The urgency of the call for munitions has, however, been reflected in a very real sense upon all and every size and type of power installation. For months now, many of our industrial organizations, in order to meet the demand for shells and other war supplies, have been operating with practically no intermission, and with the latter of the briefest possible period in any case. Such a circumstance, and the fact of its having been made possible, indicates that, whatever else we may have lacked in the initial stages when transforming our workshops into arsenals, our power resources and equipment carried a generous margin. Renewals, replacements, and additions must necessarily be an early future expectation due to the strain which all power plant apparatus is undergoing.

There is little doubt that manufacturers of power plant equipment and accessories, whether of steam or hydro-electric type, have not altogether been idle in designing and developing new and improved units. They have appreciated the fact that with the new manufacturing vision and spirit dominating the activities of our plant administrators, there will be a casting about in search of the latest and most efficient power equipment with which to lower production costs and thus meet more effectually competition. The stagnation period in the realm of power equipment and specialties has lingered longer than those akin and accessory to it, yet the bottom "touching," is now quite an event of the past, and every evidence is forthcoming that the new year will witness considerable activity in every sphere of power generation and application.

Municipal and Building

This has been more than ordinarily a lean year so far as municipal enterprise is concerned, the primary cause being of course the impossibility of borrowing the necessary capital to finance projected improvements. Building and general construction work has also been largely at a standstill for financial reasons, and while, perhaps, only something less than the annual average must be reckoned for dwellings and residences generally, a rather heavy decrease falls to be noted relative to public buildings and other large institutions. It is anticipated, how-

ever, that the opening of the coming spring will give a fillip, both to municipal and general building construction work, and there is little doubt that the New Year 1916, will easily shame its predecessor in progressive accomplishment.

Machine Tool Industry

Other than the steel mills, machine tool manufacturing plants easily take pride of place as regards activity during 1915. Canada's machine tool industry has always been embodied in the personnel of but a few firms, and while these have largely met the needs of our manufacturing plants generally, their activities for the most part stopped there. The manufacture of shells has changed things somewhat in the latter respect, so much so that we find our machine tool builders shipping products of their own design and construction to Great Britain and elsewhere, and even letting-out their manufacture abroad upon a royalty basis.

Machine tool building has been wonderfully stimulated everywhere as a result of the war, and nowhere is this more patent than here in Canada. A new departure relative to machine tool products has been the accession to the ranks of previously established builders of their confreres in other metal-working industries, the particular specialty to which the new effort is directed being the manufacture of single-purpose machines for shell making. Large numbers of these products are under construction and in service, and while the munitions industry is with us, and the difficulty of getting delivery on standard or special general purpose tools remains unrelieved, such enterprise as has been displayed is commendable and highly appreciated by those having shell contracts to fill.

Peace—What Then?

Considerable speculation has been indulged in as to what the advent of peace will bring, whether business for a lengthened period thereafter will languish or whether normal if not boom times will succeed, as a result of the general endeavor to compensate for the lack of attention to our own more immediate domestic needs. It is freely hinted that our machine shops and metal working plants cannot fail then to find themselves weighted down with war-time purchased equipment, and that even with normal prosperity, the machine tool industry will go dead to stagnation.

We have travelled far these past fifteen months from a manufacturing standpoint, further than most of us have yet been able to fully appreciate. Most estimates of industrial conditions following the declaration of peace exclude this feature, and therefore, are based on those of pre-war times. As such they are of little value and but serve to indicate that those responsible for them are wholly unaware of Canada's up-to-date manufacturing achievement. The spirit behind our already-shown enterprise, although of war birth, will not evaporate or become numbed or extinct when the war ceases, but will give expression of increased vitality in directions and spheres whose scope will be immeasurably greater than even that now experienced.

Canada has struck a new stride in manufacturing, and the equipment to maintain it, she is only in process of accumulating. What will go to the scrap heap on conclusion of the war will have worthily served its immediate purpose, and its replacement will neither, we think, be irksome nor a hardship.

Taking Time By the Forelock

What steps are being taken by our manufacturers to set their houses in order, so to speak, to make easy the transition from war time commodity production to those of peace-time, we may not divulge, nor may we indicate just how widespread the movement in that direction. Certain it is that not all who ought are preparing for the sure eventuality of the war end. It may be that the disposition to hug profits realized and in process is so keen and strong as to obscure those perhaps which are equally procurable and possessed of a good deal more permanency at their source. However the attitude of each individual manufacturing concern, the time to plan, finance, and develop the domestic and foreign campaign is right now, for the reasons that munitions manufacturing has been shorn of its difficulties and terrors long ago, allowing opportunity for a new outlook; an enlarged, and in many cases a much enlarged plant will eat its head off by inactivity, and finally because the wherewithal to finance and establish a remunerative peace-time business has been earned as the past year's records of at least our large and more prominent manufacturing corporations clearly indicate.

We were not found wanting when the munitions opportunity presented itself; we may, if we will, however, be better prepared to tackle new opportunities when the munitions manufacture ceases.

NEW DEFENSE MEASURES

AN addition to the Defence of the Realm Act, gazetted on Dec. 23, prohibits the holding without special permission from the Minister of Munitions, of any exhibition which might affect prejudicially the production of war materials. There is also a general prohibition of the exhibition of war materials. A British industrial exhibition, which was to display war materials and the method of their manufacture, was in process of organization for 1916.

King George has formally approved the following five War Measures: Finance Act No. 3, relating to Government war obligations; Act No. 2, relating to trading with the enemy; Act relating to supplemental provisions of the war loan; Act forbidding an increase in rents and interest on mortgages; War Restriction Act.

INDUSTRIAL PROSPECTS BRIGHT IN HAMILTON, ONT.

INDUSTRIAL prospects in Hamilton are bright for the coming year. The Canadian Cartridge Co., which recently completed negotiations with the city, to erect a big plant, has now taken out a building permit. In addition to extensions at the plant of the Steel Company of Canada, which will aggregate in value nearly a million dollars, a number of new industries are in sight. The Eaton Company's big four-storey building on John Street, now nearing completion, will give employment to 300 people. Early in the new year the Canadian Horseshoe Company, the parent plant of which is in Erie, Pa., will be operating full blast. The Franklin Steel Works, of Joliet, Ill., is also completing its organization. Work will be begun shortly on a five-storey factory for the W. T. Rawleigh Company of Freeport, Ill., to manufacture toilet articles. The industrial department is in touch with a number of other firms, which are figuring on locating in Hamilton.

FINANCING SHELL CONTRACTS

THE \$50,000,000 credit established by the Government for the Imperial Treasury will meet, in substantial measure, the financial requirements of the Imperial Munitions Board for some months to come. It is not expected that there will be any difficulty with the lessening demands of the crop movement upon the Canadian financial system, in arranging for a further credit of \$50,000,000 or \$100,000,000 when required, through the subscriptions of those engaged in the manufacture of munitions for British Exchequer bonds, and by the system of dollar acceptances of the purchase by the banks of short date Imperial Treasury bills. As the Finance Act of 1914 will remain in force, facilities will be available in case of need for the rediscounting by the banks of any such securities or acceptances.

Halifax, N.S.—For the eleven months ending November 30, 1915, the value of building permits issued amounted to \$936,857, an increase of \$135,317 over the like period of 1914.

The Industrial Situation Viewed From Various Angles

Contributed and Selected

Being expressions of opinion from men prominent in the administration and management of iron, steel and allied enterprises regarding developments in trade, commerce, agriculture, manufacturing, etc., during 1915, and their bearing on the immediate and more remote future outlook relative to our Dominion. More or less optimism will be found predominant.

THE POWER TRANSMISSION MACHINERY VIEWPOINT

By C. F. Wheaton*

WITH respect to the industrial situation as it appears to us to-day, also as to the probable situation after peace is restored, are glad to say as follows:

As to the present concerning ourselves, we are certainly fully occupied in all departments and have been for past six months. For eighteen months prior to that, we were running about 60 per cent. of normal. Might state that, since our business is almost altogether done with manufacturers and power users generally, we have a fairly good opportunity of being in touch with the situation, and our observation is that probably 50 per cent. of the manufacturers of Ontario and Quebec are busy at the present time, either directly or indirectly, because of war orders, but for those not thus engaged, volume is still substantially below normal and will be, we believe, until peace has been declared.

After the War.—We cannot help but think that Canadian manufacturers generally are going to be very busy as soon as it becomes known that peace has been declared. We come to this conclusion because we know that as a general proposition stocks are very low throughout the country and, on the other hand, manufacturers generally have been "recovering," until to-day no doubt a large percentage of them are in a very much better position financially than they have been for years. All this must mean renewed confidence and a lot of new business.

*Managing Director, the Dodge Manufacturing Co., Toronto, Ont.

THE MINE AND MINERAL VIEWPOINT

By C. P. Hill*

OPTIMISM may be regarded as the keynote in business circles in the Western provinces, there being more enquiries for mining propositions in Vancouver than that city has ever known. This has naturally been brought about by the great demand for copper, lead and other minerals abounding in the province of British Columbia.

There is also a great revival in the coal industry, for the fact remains that the unrivalled crop in the Western provinces and the railways rushing out three times more cars than ever before, has given a splendid market for coal. It does not stop at this. The enhanced wealth of the West has given every man, woman and child from Winnipeg to the mountains a triple purchasing capacity, and they are exercising it all along the line.

There is also nothing short of a revolution taking place in the trading capacity of the country storekeeper. He allowed his shelves to become empty, and they remained empty until a good crop was assured. Every merchant in town and village then began buying on a very large scale to the mutual profit, of course, of the wholesaler and manufacturer in Montreal and other Eastern points.

The one weak spot in the West, but it is being forgotten very rapidly, was the farmer who took a hundred dollars a year or two ago and came into town and bought a lot, the value of which was increased by a real estate agent to ten thousand dollars. With this ten thousand dollars the farmer thought he was a rich man and settled down in the city, but he soon went broke and now he is taking up more land. As a wiser and poorer man he will not likely make the mistake a second time.

*Vice-President, Pacific Coast Mines, Ltd., Vancouver, B.C.

THE STOVE AND METAL WARE MANUFACTURING VIEWPOINT

By Margaret Wade.*

THE closing months of the year just completing marks the turning point from the depression which has been so marked a condition throughout Canada during the past two years.

The crisis was met by our manufacturers generally, with an optimism and confidence so splendid, and an adaptability to the enforced conditions so ready, that they admitted of no defeat, and latterly had needed only a comparatively slight impetus to start the volume of trade once more on the upward trend. That impetus came with the satisfactory crop of this autumn, since the harvesting of which business has shown a decided improvement. The future would seem to promise during the duration of the war, healthier home trade than we have had for some time, and, if we seize the occasion rightly a very much augmented export business.

We believe there is a danger, however, that in endeavoring to meet the urgency of the sudden demand upon us, through the cutting off of supplies from former sources, some of our manufacturers may be tempted to sacrifice something of quality to expeditiousness.

The policy of "quality first" is one which we owe to ourselves as a nation, and as individual manufacturers to follow, in order to develop through the opening created by present conditions an enlarged, sound and stable trade of the future, and that greater Canada to which our unprecedented opportunities and vast resources entitle us.

The close of the war will undoubtedly bring another disruption of trade conditions, but this should be only temporary, and when it will come, or the form it will take, are, of course, beyond present conjecture.

*Editor, McClary's "Wireless," London, Ont.

THE SAW AND PULPMILL MACHINERY VIEWPOINT

By C. H. Waterous*

THERE is probably no doubt but that the actual condition of business in Canada to-day is very much better than it was a year ago, and that the general feeling is also much more optimistic. The better crops, the great demand for men and for everything required by the armies in the field, have given employment to practically all who wish to work, and have made the distribution of money so much more widespread that considerable prosperity is a natural result.

In our business, which is the manufacturing of machinery for the production of lumber and pulp, the demand during the past year has been extremely light, and we were probably among the first to be affected by the cutting down of expenses in the way of building new mills and making additions.

While it was expected that the demand for paper would be increased on account of the war, this does not seem to have been the case, the sales of paper and pulp having been, we are informed by manufacturers, extremely slow, and judging by the demand for this class of

*Manager, the Waterous Engine Works, Brantford, Ont.

machinery, we can heartily endorse the position.

There probably would have been by this time a greater cleaning out of the stocks of lumber were it possible to sesure transportation facilities, particularly water borne, but the lack of shipping has made it, we are informed, practically impossible for the holders of lumber stocks to get to consumers abroad. The destruction in Europe would probably have made a large market for timber if the material could have been gotten there.

The splendid crops in the Northwest will no doubt make a demand for lumber on the prairies; this is now depleting and will continue to deplete the stocks in British Columbia, as well as of the mills in the prairie provinces themselves. We are, therefore, I think, justified in looking for an increased trade in our line of manufacture for the coming year.

BANK EXECUTIVE VIEWPOINT

By Sir F. Williams-Taylor.*

THERE is now a decidedly more hopeful feeling throughout the Dominion, and there is excellent ground for reassurance in the material advantages that have resulted from a bountiful harvest. When we consider that the North-West alone has produced several hundreds of millions of dollars' worth of agricultural products in the past year in an area where in the boyhood of the middle-aged not a sod was turned, we feel that this is a form of genuine pros perity to inspire confidence and in which our pride is pardonable.

When we begin to analyze other features of the situation there is, however, less room for satisfaction. The war in which the Empire is engaged to protect its integrity has made it incumbent upon Canada to assist the Mother Country in every way possible. We have already provided a large number of troops and more will follow. In the manufacture of munitions, clothing and other requisites, we are doing our full share. This has brought profitable employment to Canada when sorely needed, and at the same time rendered great service to the common cause. Let us, however, remember that the manufacture of war materials is a grim and transient form of so-called prosperity, that the cost thereof comes out of the national exchequer of Great Britain or of Canada, and from the blood of the flower of our manhood.

Also the United Kingdom has advanced large amounts to Canada for military expenditure, and the time may come when it will be desirable, if not necessary, for the Dominion to finance its own requirements. In any case, we must economize in every way possible so that we may bear our full measure of responsibility during the war and be prepared for the taxation that must follow.

Canada's greatest wealth lies at her feet, and her economic future is bound up in the development of vast agricultural areas of unsurpassed fertility. The rate at which that development can be accelerated is dependent upon the rate of increase in our farming population. Immigration can best be attracted to the Dominion by reducing and keeping down the cost of living, and that, in my opinion, is the key to the whole economic situation.

*General Manager, Bank of Montreal.

INVESTMENT BROKER'S VIEWPOINT

By W. Sanford Evans*

I AM impressed by the signs of fundamental improvement in the situation in Western Canada as the result of a recent trip through the West. This year's large crop has been moving out in unprecedented volume and at prices which represent a satisfactory profit on production. Cash wheat has been bringing from 10 cents to 20 cents per bushel more than did the crop of 1913. The railways between Winnipeg and Fort William have handled more freight cars in a day than any double track or single track lines ever did before.

The proceeds of the crop are going largely to the payment of debts, and one cannot talk with men in any line of business without realizing that the past few weeks have seen an exceptional liquidation. Money is accumulating in all the mortgage companies through repayments, and there is so far a relatively small demand for new loans.

Business generally is beginning to feel the effects of the improved conditions, and these effects must gradually extend to all legitimate lines. An exhibition is now being arranged in Winnipeg of the products of some fifteen or more new factories established since the war began. I believe the general attitude towards conditions to be sane and even conservative.

There is no trouble about the conclusion that it is sound to liquidate, but the problem will be what to do with the surpluses of cash and the reserves of credit, and also what to produce and what not to produce in 1916. It is therefore on these points it will be difficult to make wise decisions without clearly recognizing what is abnormal in present conditions and without remembering the lessons of the past three years.

*Chairman, Georgian Bay Canal Commission.

BANK EXECUTIVE VIEWPOINT

By H. V. Meredith.*

THE unprecedented conditions under which trade and commerce have been conducted during the past year remain unchanged, and are the cause of constant anxiety to those concerned with financial affairs. All things considered, however, the trade of Canada has been well maintained, both as to volume and character. Natural resources continue to be developed and their product to find a ready and profitable sale, while many branches of manufacture have been employed to capacity in turning out munitions of war, the money value of which runs into scores of millions. The resulting employment of labor has been of almost incalculable advantage.

The restoration of a favorable balance in our foreign trade is a factor of supreme importance at the present time, as it enables us to conserve our gold supplies and to curtail our borrowings abroad to some extent. War contracts, of course, have contributed substantially to this feature, the value of manufactures exported having risen from $39,000,000 in the first seven months of the last fiscal year to $84,000,000 in the same period of the present year, and, as in the case of cereals, this export trade is on an ascending scale.

The position of Canada is a highly favored one, with an assured future of growth, development and general prosperity. At present, however, we live in the shadow of the great war, to which all else must be subservient. What its duration will be, and the position in which its termination will find us, can be matter of the merest conjecture. The vast armies now engaged in the struggle cannot be kept in the field indefinitely. The financial factor is daily assuming increased importance, and in this respect the advantage is unquestionably with Great Britain and her Allies.

After the war, a readjustment of trade conditions is to be expected. The flood of wealth which has attended the export of munitions and war supplies must of necessity be largely curtailed, and a new set of problems will have to be faced. Our agricultural resources and undeveloped wealth will enable us to bear any strain which may be imposed upon us, and we shall in the end come safely through the period of economic upheaval and world-wide conflict—with a larger debt, it is true, but with our ability to meet it unquestioned and our economic position not seriously impaired. In the meantime, our duty as Canadians is to watch closely the current of events, and to be prepared for emergencies and to take advantage of propitious circumstances as they arise.

*President, Bank of Montreal.

MANUFACTURING looms large in the personal constitution of every community and nation: little wonder is it, then, that with the call for men as well as for munitions, the response of this Dominion was prompt and generous. The accompanying list embraces, as far as we have been able to procure, those representative Canadian manufacturers, members of their families and administrative staffs, who have heeded the call of Empire for active service in one or other of our overseas contingents.

Major Woodman Leonard, E. Leonard & Sons, London, Ont.

Captain E. E. Williams, Dunlop Tire & Rubber Goods Co., London, Ont.

Captain Clifford T. Trotter, Standard Clay Products, St. Johns, P.Q.

Captain Harold L. Trotter, H. Holgate & Co., engineers, Montreal, Que.

Captain Harvey B. Evel, Evel Casket Co., Hamilton, Ont.

Captain H. J. Heasley, Sadler & Haworth, Montreal, Que.

Captain W. D. Greer, Consumers Gas Co., Toronto, Ont.

Captain J. T. Duguid, Imperial Steel & Wire Co., Collingwood, Ont.

Captain F. F. M. Brown, College Press, Ltd., Toronto, Ont.

Captain C. R. Crowe, Crowe Iron Works, Guelph, Ont.

Captain Smith, E. D. Smith & Son, Winona, Ont.

Captain F. R. Newman, Canadian Fairbanks-Morse Co., Toronto, Ont.

Captain J. M. Eakins, Canada Grip Nut Co., Montreal, Que.

Captain F. P. Duck, D. Acland & Son, Winnipeg, Man.

Captain G. H. Weld, Farmers' Advocate, Ltd., Winnipeg, Man.

Captain W. L. Roblin, Winnipeg Telegram, Winnipeg, Man.

Captain R. Steacie, Smart-Woods, Ltd., Montreal. (Killed.)

Lieut. Garret, Steel and Radiation, Ltd., Toronto, Ont.

Captain George D. McLauchlan, McLauchlan & Sons Co., Owen Sound, Ont.

Captain H. C. Trenaman, Domestic Specialty Co., Hamilton, Ont.

Captain J. S. Grafton, Grafton & Co., Dundas, Ont.

Captain R. A. McAvity, T. McAvity & Sons, Ltd., St. John, N.B.

Captain Victor Nordheimer, The Nordheimer Piano & Music Co., Toronto, Ont.

Captain Alexander Campbell, Campbell Steel & Iron Works, Ottawa, Ont. (Died of illness.)

Captain Walter A. Harrison, T. H. Estabrook Co., St. John, N.B.

Captain Edgar H. Shuttleworth, J. R. Shuttleworth & Sons, London, Ont.

Captain A. R. Taylor, T. W. Taylor Co., Winnipeg, Man.

Lieut. Harvey Cockshutt, Cockshutt Plow Co., Brantford, Ont.

Lieut. C. H. Ackerman, B. F. Ackerman, Son & Co., Peterboro, Ont.

Lieut. K. E. Drinkwater, A. B. See Electric Elevator Co., of Canada, Ltd., Montreal, Que.

Lieut. T. E. Ryder, Canadian Fairbanks-Morse Co., St. John, N.B.

Lieut. J. V. Young, Hamilton Cotton Co., Hamilton, Ont.

Lieut. W. L. McIntosh, Canon Lake Lumber Co., Winnipeg, Man.

Lieut. W. S. Drewry, E. L. Drewry, Ltd., Winnipeg, Man.

Lieut. G. H. Saltmarsh, Metallic Roofing Co., Winnipeg, Man.

Lieut. Wm. Martin, Jr., Manitoba Gypsum Co., Winnipeg, Man.

Lieut. B. M. Green, Smart-Woods, Ltd., Montreal, Que.

Lieut. Jack Woods, Smart-Woods, Ltd., Montreal, Que.

Lieut. Lacey, Steel and Radiation, Ltd., Toronto, Ont.

Captain Trumbell Warren, Gutta Percha & Rubber Co., Toronto, Ont. (Killed.)

Lieut. P. D. McAvity, T. McAvity & Sons, Ltd., St. John, N.B.

Lieut. E. C. H. Moore, Coleman Baking Powder Co., Brockville, Ont.

Lieut. Ian Hendrie, Hamilton Bridge Works, Hamilton, Ont.

Lieut. Geo. C. Wright, E. T. Wright Co., Hamilton, Ont.

Col. Chas. Smart, Smart-Woods, Ltd., Montreal, Que.

Col. John Gunn, Gunns, Ltd., Montreal, Que.

Pte. Alex. G. Rosamond, Rosamond Woolen Co., Almonte, Ont.

Pte. Warren Nelson, Semi-Ready, Ltd., Montreal, Que.

Capt. H. R. Cleveland, president J. L. Goodhue & Co., left Canada with the Fifth Canadian Mounted Rifles, but has since been transferred to the brigade staff under Brig.-Gen. C. A. Smart, Second Brigade, Canadian Mounted Rifles.

Capt. J. M. McIntosh, secretary, Toronto Branch Canadian Manufacturers' Association, has left for Brandon, where he has been appointed Adjutant of the 79th Battalion.

Obituary Record of Business and Public Men

The year now closing has taken toll of a rather over-average percentage of business and public men who at one time or another figured more or less prominently in the upbuilding of our Dominion. It is due them and their work that the event of their passing be here recorded.

Horatio F. Forrest, a well known civil engineer, died in Winnipeg on January 19, in his 73rd year.

William Snider, vice-president of the Waterloo Mfg. Co., Waterloo, Ont., died on March 8, aged 68.

James F. Markey, master mechanic in Toronto for the G. T. R., died suddenly in Toronto, on April 23.

Walter Stuart, of Lucknow, Ont., owner of the electric light plant and planing mill, died on Feb. 18.

Captain John McMulkin, died on Feb. 24, aged 79 years. He was New Brunswick's first factory inspector.

Robert Bowie, vice-president of the Canada Foundries & Forgings, died at Brockville, Ont., on August 13.

John Knox, treasurer of the Dominion Power & Transmission Co., died at his home, Hamilton, Ont., on Aug. 31.

Giles S. Ranson, president of the Toronto Furnace & Crematory Co., died in Toronto on Aug. 31, at the age of sixty-two.

John Oliver Parker, head of the J. O. Parker & Co., brass works, died on Feb. 27, at his residence, Toronto, aged 67 years.

Osgood McVean, senior member of the firm of O. & W. McVean, wheel manufacturers of Dresden, Ont., died there on Feb. 26.

Capt. P. M. Campbell, director of the Collingwood Shipbuilding Co., died at Collingwood, Ont., on Sept. 10, at the age of 69.

John S. Anthes, one of the oldest and best known furniture manufacturers in Ontario, died at Berlin, Ont., on April 13 in his 71st year.

Charles Stewart, one of the senior partners of Burrow, Stewart & Milne, founders, died at his home in Hamilton, Ont., on Oct. 8, at the age of 78.

Captain Murdock McLean, a well-known marine captain, died at Duluth on March 4, of heart trouble. Captain McLean was born in Kincardine 60 years ago.

Capt. Murray Wilson, manager of the cordite department of the Canadian Explosives Co., was killed on July 6, by an explosive at the plant at Beloeil, Quebec.

William H. Rowley, president of the E. B. Eddy Co., Ottawa, Ont., died suddenly in Toronto on Jan. 12. Mr. Rowley was born in Yarmouth, N.S., on March 25, 1851.

Walter D. Beardmore, head of the firm of Beardmore & Co., passed away in Toronto on May 23. Mr. Beardmore, who was in his 66th year, was born in Hamilton, Ont.

John A. Culverwell, hydraulic and electrical engineer, who for some years was connected with power development in the Trent Valley district, died in Toronto on April 21, aged 48 years.

John Cowan, president of the Ontario Malleable Iron Co., Oshawa, Ont., died at his home in Oshawa, on April 8, aged 86. Mr. Cowan was born in Tyrone, Ireland, and came to Canada in 1841.

Joseph R. Henderson, of Montreal, president and general manager of Brandram-Henderson, Montreal and Halifax, manufacturers of paints, etc., died suddenly in Halifax, N.S., on July 31.

Frederick Winslow Taylor, a well-known engineer, died at Germanstown, Pa., on March 21, aged 59 years. The late Mr. Taylor was the pioneer of scientific shop management and methods.

John G. Twiton, secretary-treasurer of the Australasian branch of the Massey-Harris Co., of Toronto, died March 18, at Melbourne, Australia, from injuries received in a motor accident.

Frank Edward Norton, manager of the Norton Telephone Mfg. Co., died at St. Michael's Hospital, Toronto, on Feb. 19. Mr. Norton was born in Fort Covington, N.Y., and was in his fiftieth year.

Richard Schofield, member of the Toronto firm of Schofield-Holden, died on Feb. 26, at San Francisco, Cal., as a result of an operation for appendicitis. Mr. Schofield was in his fifty-ninth year.

William Bissett Smith, general manager of the Dominion Transport Co., died in Montreal on November 8, in his 87th year. He was born in Huntley, Aberdeenshire, and came to Canada in 1855.

Maximilian Eugene Duncan, vice-president and general manager of the Canadian Car & Foundry Co., died on May 23, in Montreal. Mr. Duncan was born in New York City on March 28, 1862.

Col. Davenant Roger, a prominent Canadian civil engineer, died in Brooklyn, N.Y., on Jan. 20, in his 63rd year.

Col. Roger played a prominent part in the building of the C.P.R. and the Cape Cod Canal.

John Fox Lindsay, financial manager of the Canadian Consolidated Rubber Co., died after a brief illness at his home, Albany avenue, Toronto, on December 26.

A. J. Somerville, for some time president of the Ontario Lead and Wire Co., died at Toronto on March 28. Mr. Somerville was born at Huntington, Que., in 1844, and came to Toronto some 40 years ago.

J. Frank Chapman, general manager of the Thousand Islands Railway and the Oshawa Railway, passed away in July, at his residence in Gananoque, Ont. The deceased was born in Frankford, Ont., in 1863.

Hon. Geo. A. Clare, M.P., president of Clare Bros. & Co., stove manufacturers, died at Preston, Ont., on Jan. 9. Mr. Clare was born at Preston in 1854, and had been a member of the Dominion Parliament since 1900.

Saxon F. Shenstone, treasurer of the Dominion Radiator Co., died at his home in Toronto on December 25. The deceased was born in Brantford 37 years ago. He began his business career in Hamilton, and joined the Dominion Radiator Co. seven years ago.

Duncan Clark, purchasing agent of the Canadian Vickers, Ltd., Montreal, Que., died on December 21. The deceased, who was born in Scotland, came to Canada two years ago and joined the Canadian Vickers, Ltd. Mr. Clark was a man of wide experience in ship construction work, and had been employed in various shipbuilding yards on the Clyde.

Thomas Coltrin Keefer, C.E., C.M.G., LL.D., one of Canada's most noted engineers, died at his home in Ottawa, on Jan. 7. Mr. Keefer was born in Thorold, Ont., and began his engineering career in 1836. In addition to his work on railway construction, Mr. Keefer was an authority on harbors and waterworks, being connected during his long career with many important undertakings.

Sir William Cornelius Van Horne, K.C.M.G., at one time president of the C.P.R., died in Montreal on September 11, following a comparatively brief illness. Sir Wm. Van Horne was born at Joliet, Ill., on February 3, 1843, devoting practically his whole life to railroad work. In recent years he took a leading part in railway development in Cuba, and he has been interested in many large railway, industrial and financial enterprises.

Thomas Leopold Willson, a well known engineer and scientist of Ottawa, Ont., died in New York on December 20. Mr. Willson was born in Princeton, Ont., in 1850, and was educated at the Collegiate Institute, Hamilton, Ont. He made many scientific discoveries during his career, the most important being in 1888 when he evolved a method for producing acetylene gas from calcium carbide and utilizing it for illuminating purposes on a commercial basis. Acetylene gas had been known for some years previously, but no method was known of generating the gas in sufficient quantities for ordinary use. Mr. Willson's discovery thus revolutionized this system of illumination. Mr. Willson also invented and perfected mechanical apparatus for bringing this gas to a practical use. One of these devices was an acetylene gas buoy, now in use as an aid to navigation all over the world. His most recent discovery was that of a chemical fertilizer, for the production of which he had received a large concession from the Newfoundland Government.

NEW WAR LOAN COMING

AN intimation that there may be a further Canadian loan, and that its amount may be $300,000,000, was given by Sir George Foster, Minister of Trade and Commerce, in an address before the People's Forum in Ottawa, a few days ago.

Sir George, after pointing out that finance was a vital factor in the present war, stated that the people of this country had already subscribed a $100,000,000 loan. If necessary, and Sir George appeared to think it might be, they could subscribe $300,000,000.

"During seventeen months of the war we have done nothing specially to tax ourselves in Canada," said Sir George, and I am certain that the people of Canada as a whole have a very inadequate sense of the gravity of the world situation which is facing us."

There were three prime factors in the war—men, munitions and third and most important, money. How long would Canada go to the Mother Country and ask her to finance her expenditure?

"We have the money. There are two sources—what the people have earned and saved. If the latter is not enough, when all your savings are gone we will come to you for your earnings. I believe there is not a man in Canada, if he values his country and citizenship, will refuse the call."

CENSUS OF CANADA'S INDUSTRIES

A CENSUS of Canada's industries and manufactures will be taken by the Census and Statistics Department, Ottawa, between January 1 and 21, 1916. In order to make the data to be procured of immediate service and value, the commercial and industrial interests concerned are requested to give prompt attention to the schedules which have been distributed in the matter of having them filled in correctly and completely. Where less than three industries of a kind are to be found in a district, province, or in the Dominion, presentation will be made in the final statement under the heading of general.

The information called for will be treated as strictly confidential, will not reveal any individual business, will not be used as a basis of taxation or other liability, and will not be disclosed to any municipal or provincial authority, or to any other Department of the Dominion Government. The contents of the schedule will show number of employees, wages paid, salaries paid, capital employed, materials of production, products manufactured, days of plant operation, etc.

As a special object of this particular census is to measure the extent to which Canada's industries have been affected by the war, products for general or peace time purposes are required to be stated separately from those attributable, directly or indirectly, to war account.

INDUSTRIAL PEACE PREVAILS IN CANADA

A SITUATION which promised for a time to become serious has been brought to an amicable close by a notification from the Canadian Northern Railway to the Labor Department at Ottawa of the company's acceptance of the findings of the Conciliation Board, which recently passed upon the dispute with its locomotive engineers and firemen. As a result of this finding, employees on the Eastern Lines of the C.N.R. system secure considerable benefit in wage rates and conditions.

The acceptance of the award by the railway company leaves the industrial situation in Canada peaceful beyond all precedent during the fifteen years covered by the Labor Department records. Not one strike is reported as existing from sea to sea, and there is no indication of serious friction at any point, although Conciliation Boards at the moment exist at St. John, N.B., where the 'longshoremen are negotiating a new agreement with the ship-owners; and at Edmonton, where the street railway men are seeking a new agreement with the municipality.

Work continues peacefully at both points pending the investigations, and, as the dispute in neither case presents any serious difficulty, there is every reason to suppose the various boards will be able to effect working agreements.

Vol. XIV. DECEMBER 30, 1915 No. 27

THE SHELL COMMITTEE, ITS WORK ITS JUSTIFICATION

DURING the past week much currency was given the report that Brig.-Gen. Bertram, deputy chairman, and C. B. Gordon had resigned from the Imperial Munitions Board, recently constituted at Ottawa. Unqualified denial has been given the rumors, and indications are not wanting that as regards the sponsors of the latter, the wish was father to the idea. Slugging the late Shell Committee and fawning on its more impressively titled successor seem to afford a never-ending opportunity and provide an ever-ready theme—although worn threadbare long ago, for the display of vituperation and the formulating of odious comparisons.

The constitution of the Shell Committee was in its every feature a new departure so far as this Dominion was concerned, and, like every other new undertaking, but more so because of the lack of precedent as a guide, the needed development of administration, the investigation into our metal-working plant resources and their pressing into service at highest possible individual capacity rating, accomplishment of results was necessarily slow in the earlier stages. Achievement did come, and for the greater part of these last twelve months we have been reaping the benefit of deliberate, responsible, conscientious application on the part of the Shell Committee executive to the work of utilizing our metal-working plant resources to an extent never before believed possible.

Our manufacturing capabilities since the advent of shell making have developed one hundredfold, and but for the effort expended in experimenting with and mastering the details of shell production by Brig.-Gen. Bertram and Col. Cantley—the two best abused men in Canada to-day, business inactivity and war aggravated poverty would have been rampant with us. The services rendered by both men are appreciated to the full by every right thinking and properly informed citizen of this Dominion, and such accomplishment as may be achieved by the Imperial Munitions Board will constitute but the superstructure to the foundation which they have so well laid.

Brig.-Gen. Bertram is to be commended for sticking to his re-appointed work, even though it does exasperate his detractors. It proves him to be a man, clean, honest and upright in whatever he undertakes, and makes the most effective weapon of defence he can employ to silence his ill-advised and equally ill-informed critics.

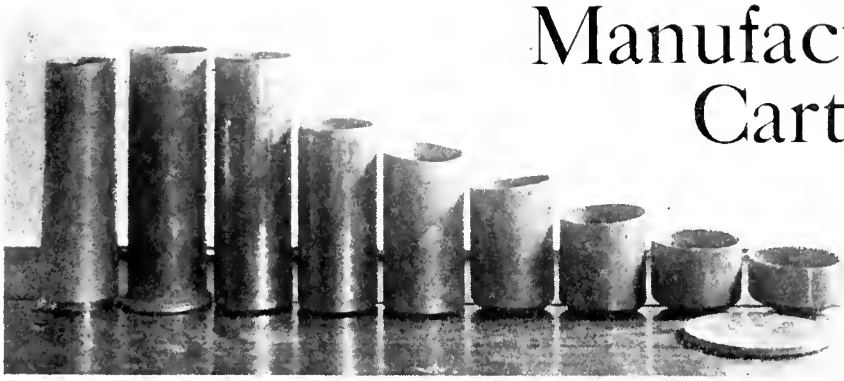
TAXATION OF WAR PROFITS

THERE is a manifestly growing tendency towards the belief that our manufacturers engaged in the production of munitions of war are waxing rich, and expression has been given the idea by suggesting that the time is opportune to tax their profits—or more properly, their super-profits on behalf of our national revenue.

Our present metal-working plant activities have no parallel in the past, for the reason that no such demand as that existent, and no such quantity specialty were aforetime realizable. The manufacture of shells has brought about a new conception of and given a new standard to plant capacity. Has it, however, enabled us to do much more than get on a par of sufficiency and efficiency with older established nations in catering more fully to our own needs and acquiring an entrance to or appropriating more of the world's trade? We believe little beyond this has yet been accomplished, and in the matter of profits being realized, no Canadian manufacturers, we believe, are netting more than arise from long, continued capacity operation. War profits taxation is, to say the least, a somewhat indefinite proposition. It has the earmarks of being so comprehensive in its scope as to even include normal business revenue arising out of war orders, and there is little doubt that such an intention is implied. On such a basis, taxation of war profits so-called is sure to meet with strong opposition and remonstrance

Overmuch irresponsible glorification of our munitions' production achievement has been broadcast, and, still more unfortunate, overmuch stock market play has been indulged in. The tax gatherer as well as the man in the street note particularly the latter circumstance, but find difficulty in determining whether abnormal manufacturing profits are being pocketed by our large corporations engaged in the production of munitions or whether "lamb fleecing" only is being assiduously prosecuted. The stock market records of recent months have had more to do with the initiation of the movement towards war profits taxation than all other evidences or reasons combined.

Will the placing of a War Profit Tax reveal the situation, or will its application be lacking in scope and therefore effect? Unless all business arising out of the manufacture of war munitions, fulfillment of other war contracts, and stock exchange values of concerns engaged in these, are under direct Government control, it seems to us futile to even attempt legislation. Judiciously placed fair profit contracts would render super profits unobtainable, thereby obviating the necessity for a War Profit Tax.



Manufacturing Brass Cartridge Cases for 18 Pdr. Shells

Staff Article

When the problem of producing brass cartridge cases first came before Canadian manufacturers, one of the chief drawbacks to immediate output was the inability to secure the necessary special equipment. The plant here described, upon making inquiries, found that delivery of the latter could not be made within nine months. However, being obsessed with the desire to bear a part in meeting our Empire need, the management got to work and adapted their existing machinery to the purpose, achieving success exceeding every expectation.

THE work of producing brass cartridge cases for 18-pdr. shells is characterized by some interesting metal drawing operations which, along with the annealing processes, constitute the greater part of the work. The metal from which these cases are made has to conform to close physical specifications after being worked; a certain tensile strength is indispensable, and is closely indicated by certain limits of hardness on the scleroscope testing machine. The composition of the metal is approximately 70 per cent. of copper and 30 per cent. of zinc.

The blanks that are used in the making of cartridge cases are seldom produced in the plant where the cases are being manufactured, as it is more economical to purchase these from some outside source, where the production of this class of work is carried on continually.

These discs are 6.22 in. in diameter, .380 in. thick, and are punched from a sheet which has previously been rolled to this thickness. When the discs are received at the drawing plant they are usually in an annealed condition, ready for the first operation. The plant from which the accompanying data was obtained performs this cupping operation on a large Niles-Bement-Pond bulldozer, a view of which is shown in the rear of Fig. 1. The cup as it comes from the press has an outside diameter of 4.5 inches, and a height of about 2.625 inches, with wall of an approximate thickness of 17-64 inch.

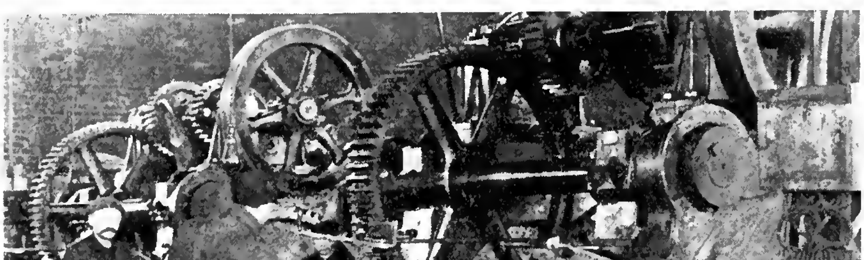


FIG. 1. FIRST AND SECOND OPERATIONS BEING PERFORMED ON A BULLDOZER.

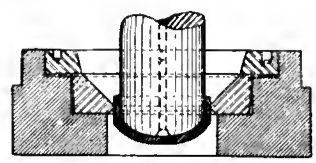

FIG. 2. SECTION OF CUPPING DIE.

A sectional view of this cupping die is seen in Fig. 2. The upper surface of these dies is beveled at an angle of 45 degrees to facilitate the action of the metal. The details of the first drawing die are shown in Fig. 3. In this case the angle of draw surface is about 15 degrees off the direction of the draw.

Annealing the Shells

To restore the ductility of the metal, which the drawing and redrawing operations tend to destroy, it is necessary to thoroughly anneal the brass before each redrawing operation. The furnaces used for the heating of these semi-finished cases are of the continuous type, built by the Quigley Furnace Co., equipped with Bristol recorders; a view of these furnaces is shown in Fig. 4. Open-

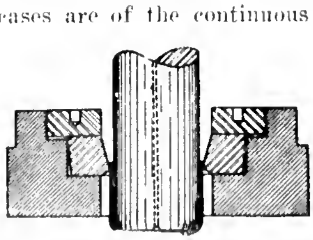

FIG. 3. SECTION OF FIRST DRAW DIE.

FIG. 4. ANNEALING FURNACES SHOWING CHARGING ARRANGEMENT.

ings are provided at each end to allow the trays to pass completely through the furnace during the process of heating. The sheet metal trays, holding about 60 cases, are placed upon steel frame buggies, the tables of which are on a level with the bottom edge of the fire chamber.

To operate the furnace, one of these trucks with a loaded tray is wheeled into position before the charging entrance; the fire door is raised and the tray shoved into the furnace by the action of the ram—operated by compressed air—shown in the foreground. This process is repeated every six minutes, and with the furnace containing a charge of six trays the time taken to heat the shells to the desired temperature of 1,150° F. is about 36 minutes. Rollers are provided on the trucks, and also on the bottom of the furnace chamber, to facilitate the progressive movement of the trays through the furnace.

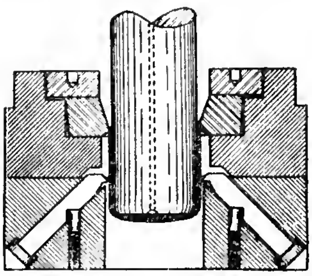

FIG. 5. SECTION OF SECOND DRAW DIE.

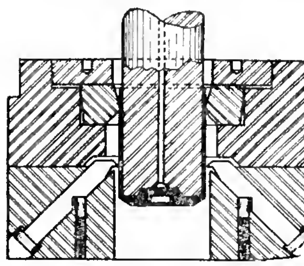

FIG. 6. SECTION OF THIRD DRAW DIE.

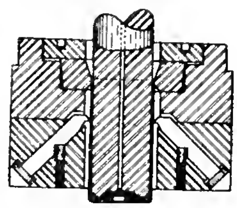

FIG. 6a. SECTION OF FOURTH DRAW DIE.

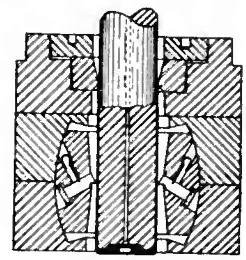

FIG. 6b. SECTION OF FIFTH DRAW DIE.

When the cases reach the far end of the furnace, and have attained the required degree of heat, they are taken out and placed on an elevator platform, which is lowered into a vat of water by means of a compressed air hoist, directly over the cooling bath. Some cartridge case manufacturers prefer to let the cases cool off in the air, believing that the sudden cooling of the immersion method affects the physical properties of the brass. Many concerns, however, have found the water cooling method perfectly satisfactory, and as this process is much quicker than air cooling, it has been generally adopted. From the cold water bath they are placed in a weak solution of sulphuric acid for a period of 12 minutes, then dipped in a bath of diluted potash solution, afterwards being thoroughly rinsed in hot water.

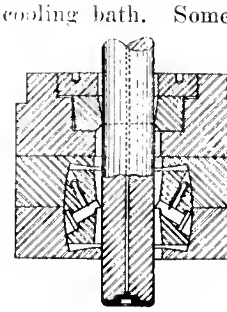

FIG. 8. SECTION OF SIXTH DRAW DIE.

First and Second Redrawing Operations

The first redrawing on the cups is also done on a Niles-Bement-Pond bulldozer, shown in the foreground of Fig. 1. The cups are dipped in a lubricating solution of soap and water, and placed upon the nose of the redrawing punch; these punches are provided with a vent hole through the centre to allow the enclosed air to escape freely. If the punches were left solid, this air would in all probability be compressed to such a pressure that the case would be seriously buckled or possibly destroyed. The operator is shown in position just after having placed one of the cups upon the nose of the punch. As the advancing ram forces the die over the punch, the metal is drawn upwards around the punch; the size of the case after the first redrawing operation is about 4.219 in. outside diameter x 3.5 in. high, with a wall approximately 11-64 inch thick.

The shells are again annealed in the same manner as previously described, and then redrawn on the opposite side of the large bulldozer shown in Fig. 1.

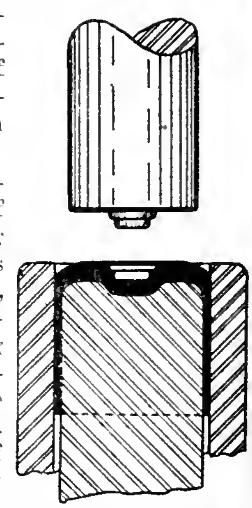

FIG. 6c. SECTION OF INDENTING DIE.

Fig. 5 is a sectional view of second drawing die, which is similar to Fig. 3, with the addition of stripping fingers to remove the case from the punch. The details of the third draw die are seen in Fig. 6. Oil and

FIG. 7. TRIMMING CARTRIDGE CASES BEFORE TAPERING.

tallow with soap and water are the lubricants used.

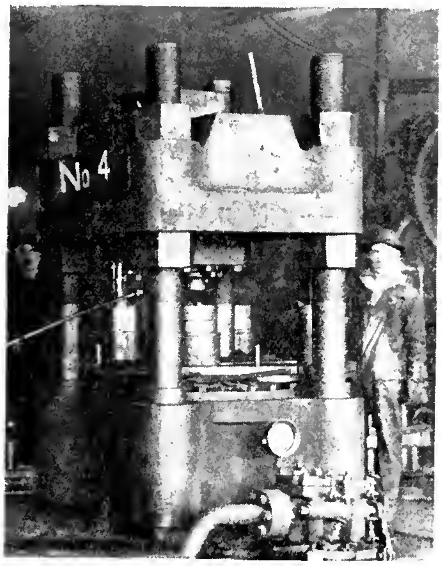

FIG. 9. HEADING CARTRIDGE CASES ON 500-TON HYDRAULIC PRESS.

First Indenting

The semi-finished cases now receive their first indent or impression in the base. This is performed on a Niles hydraulic press, equipped with special table fitted with dies. This table is permitted to revolve about one of the standdards of the press, and can be locked at each quarter turn, when the stationary punch and one of the dies are in working position. The ram of the press is forced upward and the impression made in the base of shell; as the ram descends the case previously indented is ejected from the die.

FIG. 9a. SECTION OF HEADING DIE.

After receiving this first indent, the cases are again passed through the annealing process in preparation for the third redrawing operation.

FIG. 10. ANNEALING FURNACES PREPARATORY TO TAPERING CARTRIDGE CASES.

Third and Fourth Redrawing and Second Indenting

These operations are very similar to that of the second redrawing, and are performed on Niles-Bement-Pond bulldozers like those shown in Fig. 1, but smaller.

Between each redrawing operation it is necessary to anneal the cases to remove the brittleness induced in the metal by the action of the dies and punches.

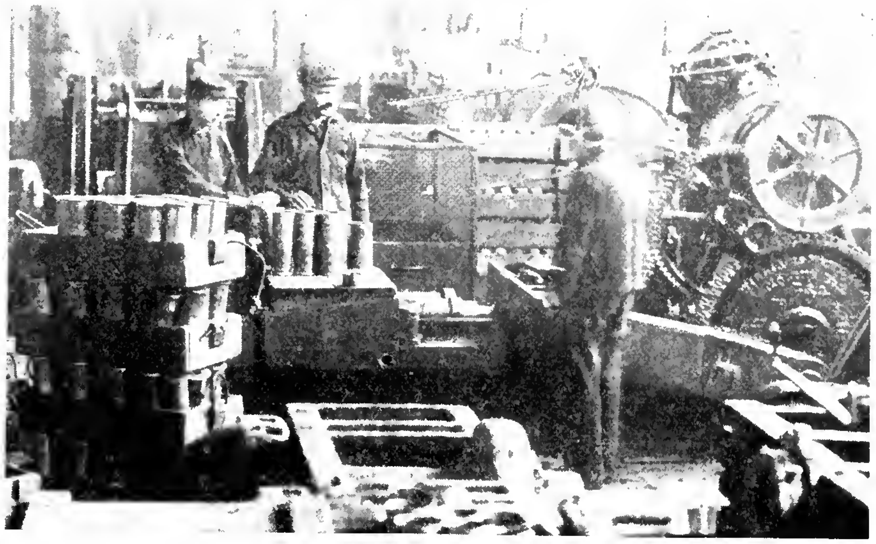

FIG. 11. TAPERING CARTRIDGE CASES ON A BULLDOZER.

The respective dimensions of the shells after the third and fourth redraw are 3.97 in. and 3.84 in. in diameter, with lengths of 5.75 and 8.25 in., the thickness of the metal in the wall being 3-32 and 3-64 in.

Prior to the shells receiving their second indent—which is performed in the same press as that used for the first—a small hole is drilled in the centre of the base to permit the escape of the contained air.

Fifth Redraw and Preliminary Trimming

The partly completed cases are again annealed and taken to an old Niles-Bement-Pond planer having the draw-punch mounted on the cross-slide, supported by the side frames, the dies with stripping fingers being held on a fixture bolted to the movable table.

The general construction of this die

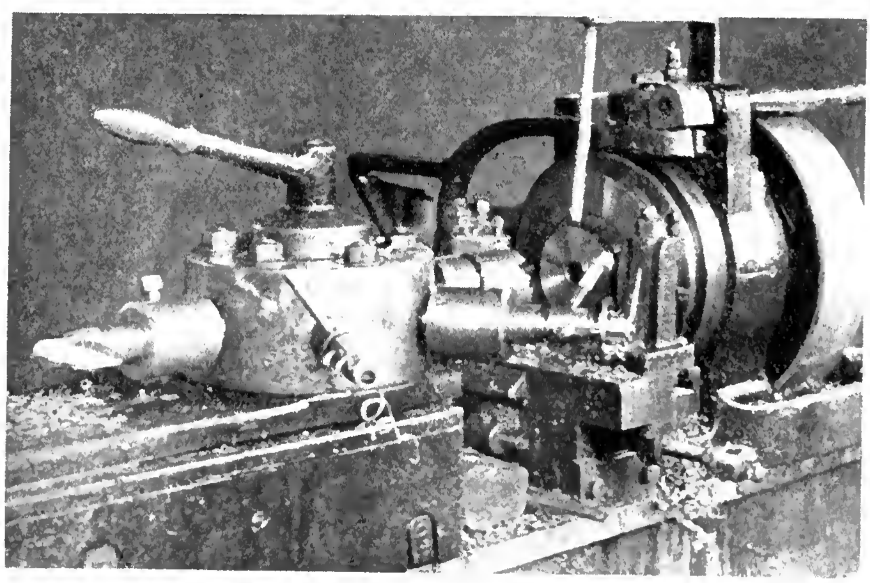

FIG. 12. MACHINING HEADED END ON SINGLE PURPOSE LATHE.

and also that for the sixth re-drawing operation is shown in Fig. 8. The case at this stage has an outside diameter of 3.78 in. and about 10.6 in. long with a wall of about .03 in. thickness.

The cases are now taken to a Canadian Car and Foundry trimming machine shown in Fig. 7. and the open end trimmed off, leaving the shell 10.5 in. long. The trimmer used was made from an old lathe with a mandrel secured to the spindle and a cutter placed in the desired position. A rest is bolted to the bed of the lathe and carries a pinion secured to a short shaft, the outer end of which connects with a lever. The raising of this lever forces the slide forward and the case is cut to the required length.

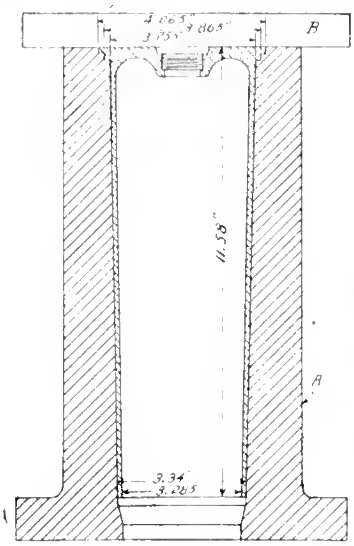

FIG. 14. GUN BARREL TEST GAUGE.

Sixth Redrawing and Final Trimming

The cases are again annealed by the cold bath process and taken to a Williams & White bulldozer partly shown in the foreground of Fig. 11. The die used on this operation is similar to that shown in Fig. 8. and the shell as it comes from the die is over 13 inches in length with an outside diameter of 3.39 in.

The cases now receive their final trimming and are cut to an overall length of 11¾ in. This is also performed on a device similar to that shown in Fig. 7.

FIG. 15. GENERAL VIEW OF FINISHING AND TESTING DEPARTMENT.

Heading the Cases

The operation of heading the cases is done in a large 500-ton hydraulic press made by the C. P. Railway and is shown in Fig. 9. The man to the right places the cases in the die, and disengages and revolves the table to working position: the operator in the centre now permits the ram to ascend, when the punch on the upper bolster makes the first impression. The ram is now lowered and the operator to the left with rod in hand places the auxiliary block over the nose of punch; the lower part of this piece finishes the heading when the ram is again forced upward. When the table is revolved so that the finished case is before the centre operator a small pneumatically operated ram ejects the headed case, which is shown in the figure about to be removed. Two similar presses are used on this operation with an average output of about 180 an hour.

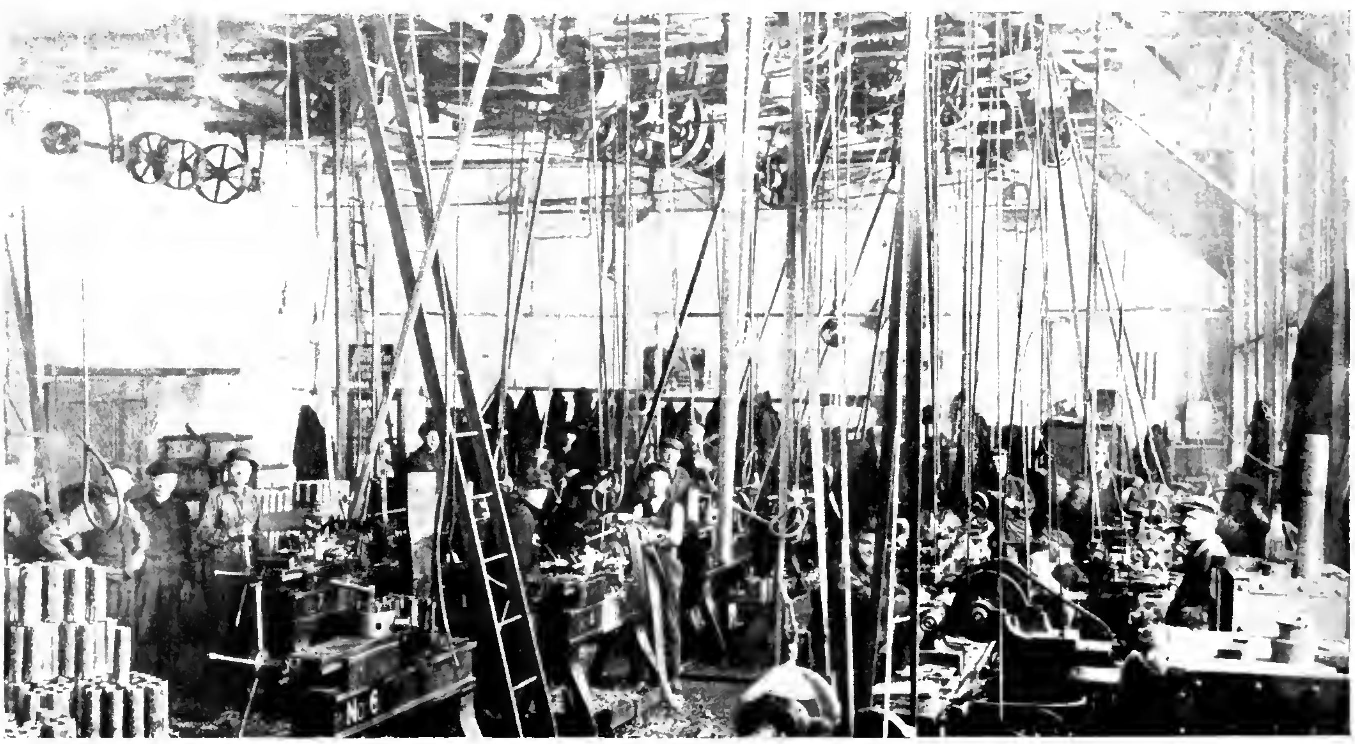

FIG. 13. GENERAL VIEW OF CARTRIDGE CASE MACHINING DEPARTMENT.

Annealing and Tapering

After the cases have been headed they are ready to be tapered; but it is neces-

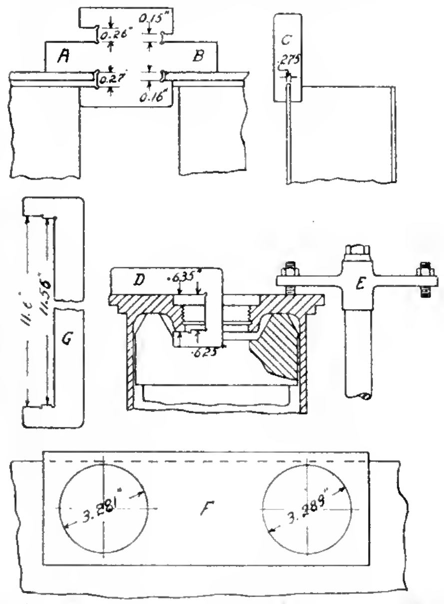

FIG. 16. VARIOUS TYPES OF GAUGES.

sary that the upper portion of the shell should be annealed before closing. The furnaces used for this purpose are shown in Fig. 10, and were constructed by the Canada Car and Foundry Co. The operator with a pair of tongs places the case in the fire chamber from below and permits it to rest upon a post, which revolves constanly by means of a small pneumatic drill arranged below the furnace. The shell is allowed to remain exposed to the fire for about 45 seconds and is heated for a distance of

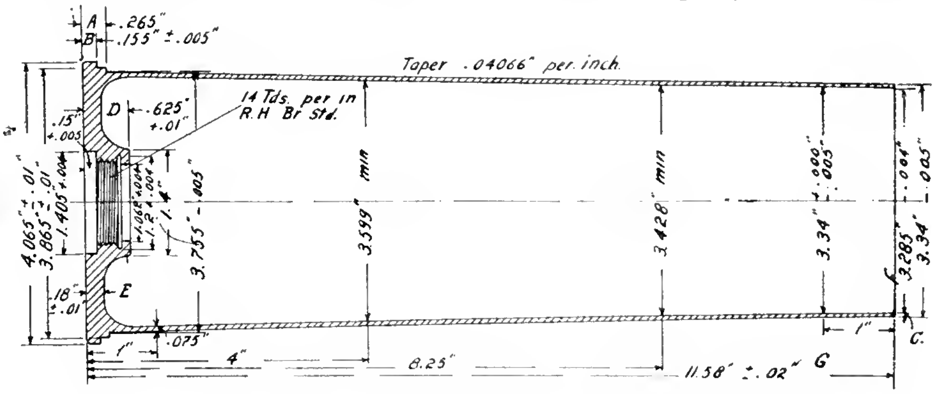

FIG. 16a. PARTICULARS OF FINISHED 18-PDR. SHELL CARTRIDGE CASE.

5 or 6 inches from the open end, after which it is allowed to cool in the air.

During this annealing operation, it is essential that the cases be heated very evenly and cooled uniformly to insure the metal being of suitable softness throughout, as irregular annealing will cause the case to buckle or produce walls of uneven thickness, while undergoing the tapering process.

The tapering operation is performed on a Williams, White & Co. bulldozer, shown in Fig. 11. Two operations are required: the operator on one side places the case in one die to receive the first taper, and on the return stroke of the press, this partly finished case is removed and handed to the other operator, who places it in the other die for the finish tapering.

In the first operation the case is tapered for a distance of about 6 in. from open end and the final tapering opera-

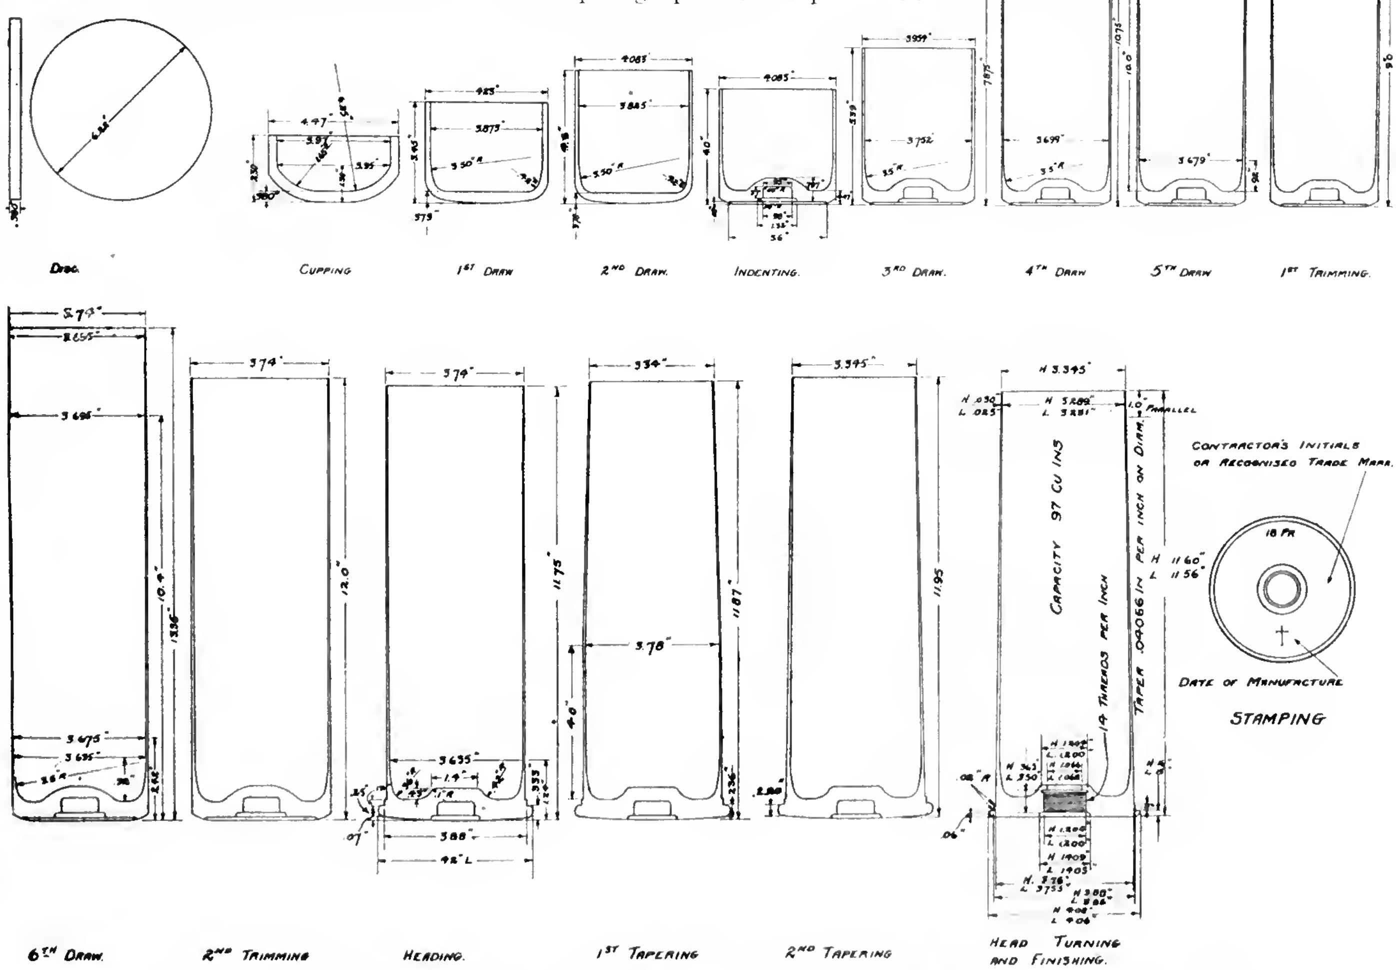

FIG. 16b. CARTRIDGE CASE FOR 18-PDR. Q.F. SHELL, IN ITS VARIOUS STAGES OF MANUFACTURE.

tion leaves the mouth of the case parallel for one inch, having an outside diam. of 3.34 in., with an allowable limit of —.005 in. The taper of barrel is about .0407 in. on the diameter for every one inch in length.

Machining the Headed End

The cases have now passed through all the drawing operations and are taken to the machining department for the final work before inspection.

Six C. M. C. and three Bullard single-purpose machines with turret heads are used on these operations. A view of one of the C.M.C. lathes is shown in Fig. 12. The cycle of machining follows: Rough bore primer pocket; face head; form with tool on rear of carriage; recess at base of thread; tap with Murchey collapsible tap; ream with combination reamer. A general view of the machining department with a section of the tool room on the right, is shown in Fig. 13.

Preliminary and Final Inspection

In Fig. 15 is shown a section of the finishing and testing department. A Noble & Westbrook marking machine is seen in the left foreground; this is for stamping the head. At the extreme left are several operators sizing the primer hole with hand taps. A plentiful supply of compressed air is available for the removal of cuttings.

Before the cases pass to the Government inspectors, they are carefully examined by the shop inspectors. The regular routine of testing is: 1st, thickness of head, shown at E, Fig. 16; 2nd, taper of barrel by snap gauges; 3rd, complete length, G; 4th, outside of head to base of primer, D; 5th, hole diameter, plug gauge; 6th, root of thread; 7th, lower rim, snap gauges; 8th, head thickness, A; 9th, flange thickness, B; 10th, diameter of outer counterbore, plug gauge; 11th, pocket recess; 12th, thickness of wall, C; 13th, testing diameter of mouth, F; 14th, gun barrel test shown in Fig. 14. The case must fit freely, yet closely, into the cast iron gauge, A, and the straight-edge, B, must pass clear above the head.

The dimensions with the high or low limits are shown in Fig. 16a. In some instances the minimum sizes are given with the allowable limit above, as these dimensions must not be below the size specified.

In addition to the gauging of the sizes within the limits indicated, the effects of the annealing operations have to be carefully checked by means of the scleroscope. The readings adopted vary with different plants, as slight differences in the composition of the metal may alter the final reading. As a general statement, it may be said that when the metal is too soft, the case may receive a permanent set under the pressure of the explosion in the gun chamber, causing it to stick or jam. On the other hand, metal which is too hard may develop cracks in course of manufacture and use, which is equally objectionable. Every effort is made, therefore, to avoid damage to the alloy when preparing the metal, as carelessness in this respect cannot be counteracted at a later stage either by heat treatment or mechanical means.

FIG. 17. GROUP VIEW OF CARTRIDGE CASES AT VARIOUS STAGES OF COMPLETION.

A group view of the various stages of completion is shown in Fig. 17; from right to left the operations are as follows:—Blank, cup, first draw, second draw, first indent, third draw, fourth draw, second indent, fifth draw, sixth draw, trim, first taper, finish taper.

The present output of this plant is about 2,200 cases per day.

MELTING POINT OF TUNGSTEN

THE intrinsic brilliancy of tungsten filaments just before melting is, according to Irving Langmuir in a recent issue of the Physical Review, 7,200 international candles per square centimetre. This would, in accordance with the constants of Nernst, Pirani, Wartenberg, and Coblentz, correspond to a melting-point of tungsten of 3,540 deg. Cent. absolute instead of the previously accepted value of 3,200 deg. Cent. As the presence of minute amounts of hydrocarbon vapors (from the vaseline or stop-cock grease) made these determinations somewhat doubtful, Langmuir recently re-determined the melting-point of tungsten by two methods.

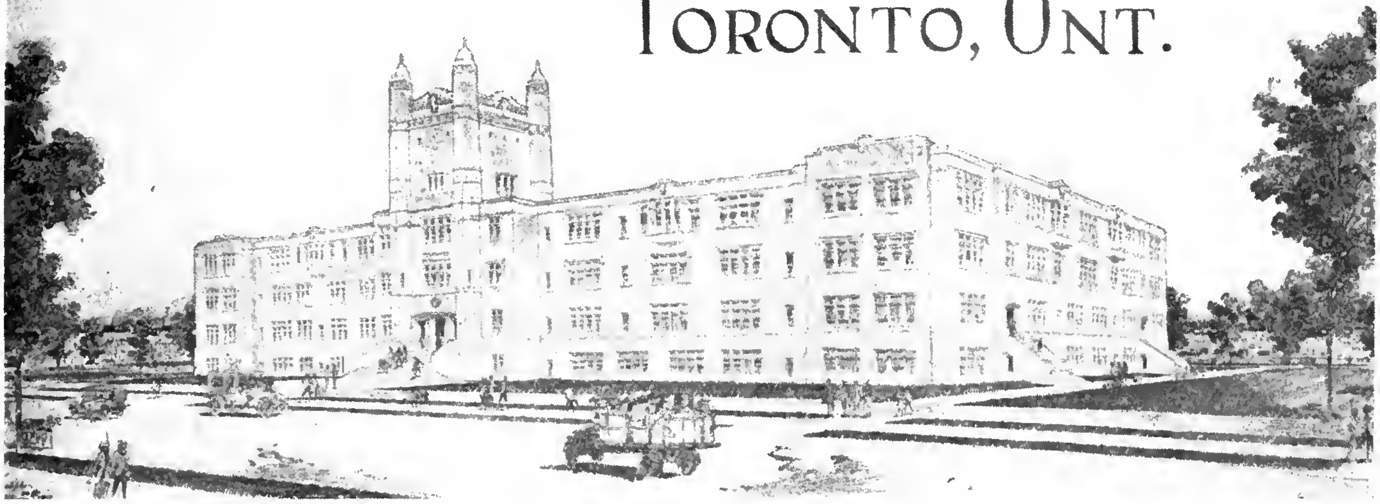
In the first he determined the black-body melting point of large filaments in nitrogen, while estimating the emissivity of helically-wound filaments of various sizes in vacuum and in nitrogen. In the second, he measured the brilliancy of a surface of molten tungsten, simultaneously determining the brilliancy of the image of a second surface of molten tungsten reflected in the first; thus he directly determined the reflectivity of the molten metal. For this purpose he made use of an alternating arc between tungsten electrodes in nitrogen; the ends of the two wires formed convex molten surfaces showing multiple reflections of the two electrodes which could be watched for an hour or more. The resulting melting-points of three determinations were: 3,540, 3,532 and 3,566 deg. Cent. absolute, the value 3,540 being the most probable.

WHITE STAR LINER BRITANNIC COMPLETED

THE largest British-built steamer, the White Star liner Britannic, was recently completed, and placed in dry dock at Belfast preparatory to starting on a few days' trial trip. The vessel is one foot shorter than her Cunard rival, the Aquitania, but is 3,000 tons heavier in gross register. Forty-eight lifeboats are carried, which can be lowered on an even keel, even though the ship be down by head or stern, and there is a device for transferring the boats across the deck so that all can be lowered on either side. The gross tonnage is 50,000. Other particulars are nine decks; 900 feet long; accommodation for 2,600 passengers, and a crew of 1,000; sixteen transverse bulkheads and a double skin; rudder weighing over 100 tons; furnaces numbering 150; wireless telegraphy with a range of 2,000 miles. The Britannic was launched about eighteen months ago, and has cost over one and a-half millions sterling.

New Central Technical School

Toronto, Ont.



Staff Article

The year 1915-16 will be memorable in the annals of technical education in Canada. The additional facilities afforded by the new building were expected to be more than ample, but the excellence of the arrangements has so increased the demand for tuition that overflow attendances in all departments have taxed the new institution to the limits of its capacity.

IN the year 1891 A.D. the City of Toronto organized evening classes, which were held in a building known as Wycliffe Hall, the classes being conducted under the name of the Toronto Technical School. Ten years later the increased demand for technical education had necessitated the purchase of a building of considerable size adjacent to the University buildings, day classes being added to the evening classes at this time. In 1904 the Technical School Board, the High School Board and the Public School Board were replaced by the present Board of Education, and under this board the school was organized as a Technical High School.

In 1911 the school was placed under the management of an Advisory Industrial Committee, appointed by the Board of Education. This committee consists of twelve persons, six of whom are selected from the Board of Education, and six from the manufacturing or other industries; three of the latter being employers of labor or directors of companies employing labor, and three being employees.

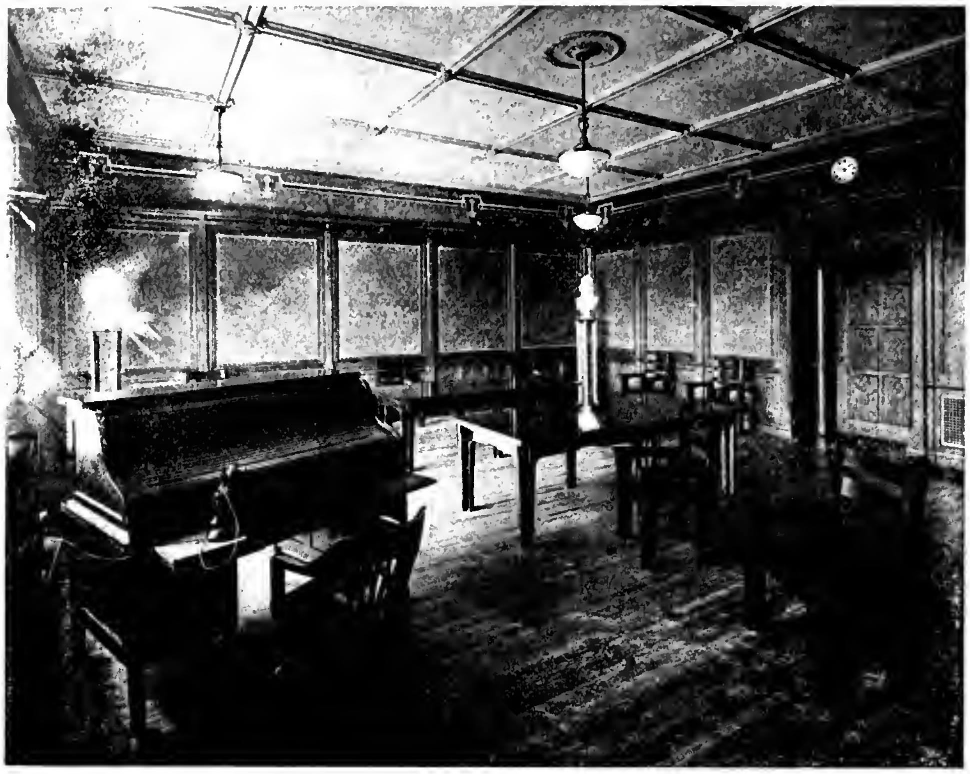
In November of that year, and twenty years from the organizing of the original Toronto Technical School, the Advisory Industrial Committee, acting under the recent Industrial Education Act, adopted a scheme of reorganization, which culminated in the erection and equipment of the magnificent edifice known as Central Technical School, Toronto.

A. C. McKAY, B.A., LL.D.,
Principal of New Technical School.

In conjunction with the Central School are four branch technical schools, which are situated in selected locations in the suburban districts; but it is with the Central School, its building, its equipment, its facilities for the dissemination of knowledge, and its devoted staff and enthusiastic pupils, that this article deals with primarily.

Instances frequently come to light where men, handicapped by lacking of opportunity for acquiring knowledge in their young days, have succeeded in surmounting many difficulties and ultimately achieved notable success in industrial life. The world-wide recognition of the value to a nation of an intelligent, educated population, trained to develop its own leaders and workers in industrial life, has been the compelling force of the immense advance in technical education in the

leading civilized countries. The phenomenal development of all classes of industry in America during the last three decades has been facilitated in no small degree by the efficient and complete education offered by numerous scientific schools and institutions which have kept in close touch with the leading manufacturing concerns on the continent.



BOARD ROOM AND OFFICE OF PRINCIPAL.

In the university departments of applied science in Toronto and Montreal, Canada has excellent educational institutions, which enable scientific knowledge to be acquired in a high degree of completeness, but the great number of young people desiring to acquire a useful knowledge of arts and crafts, trades and special industries, have not been given the facilities which are their moral due.

The scheme of reorganization adopted by the Advisory Industrial Committee stated that in the Central School there should be organized the following courses:

For Day Pupils:—

(a) Industrial courses (general and special), extending over four years for boys, and over three years for girls; one-half of the time in the last two years in each course to be devoted to actual shop practice.

Pupils to be admitted to these courses are required to present a certificate of having obtained at least fourth form standing in a public or separate school.

(b) Matriculation courses, extending over four years, admitting to university departments of applied science and household science.

Pupils to be admitted to these courses are required to be duly qualified to enter a high school.

(c) Special short courses of theoretical and practical technology, including courses for part-time students; pupils to be admitted at the discretion of the principal.

(d) Courses in fine and applied arts, with special adaptation to the industries; pupils to be admitted at the discretion of the principal.

For Evening Pupils:—

(a) Industrial courses, with practical demonstrations under the direction of skilled workmen, open only to those actually engaged in the trade or occupation.

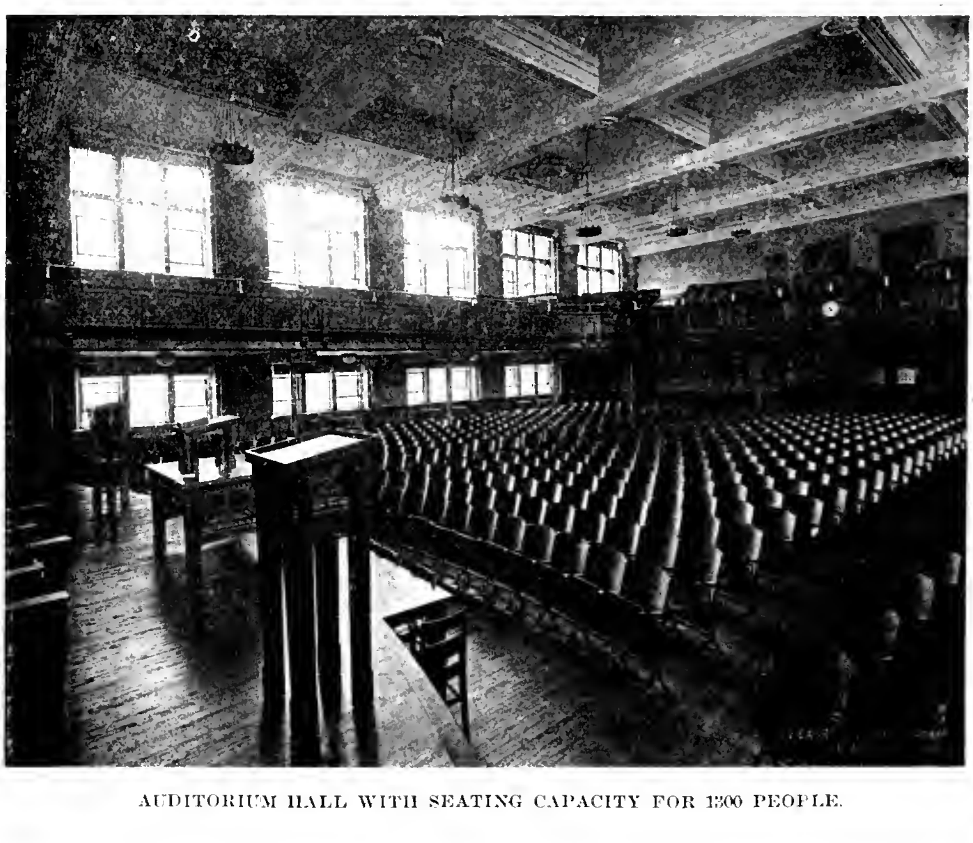
(b) Technical courses, including theoretical and applied mathematics.

(c) Art courses, with special adaptation to industries.

(d) Domestic science courses.

A study of these provisions reveals to a slight extent only the amount of detailed labor and thought involved in organizing the new educational plant. To remove an organization with its existing equipment, which was already of considerable proportions, into new quarters six or eight times as large, to increase the staff, to extend the equipment, to maintain every administrative and executive detail in a high state of efficiency, and then, in spite of all precautions, to be overwhelmed with an avalanche of students beyond all previous estimation—such in brief has been the fortune of Dr. A. C. McKay, B.A., LL.D., principal of Central Technical School.

The site of the school extends to about six acres, and occupies two city blocks. It is bounded by Lennox, Harbord, Borden, and Lippincott Streets. The main entrance is on the west side facing Lip-

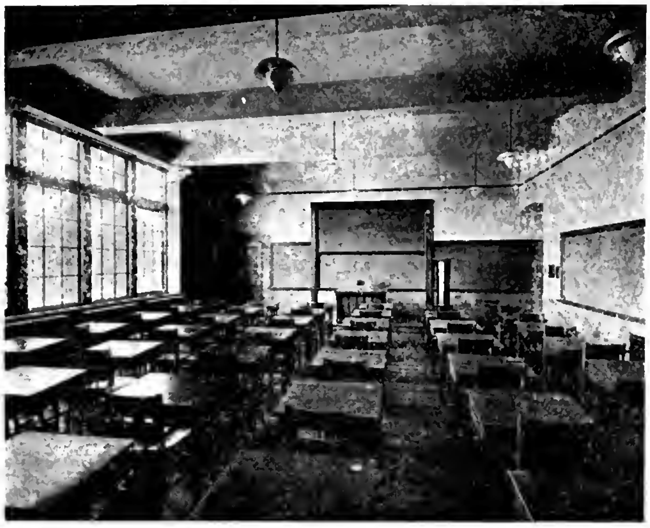


AUDITORIUM HALL WITH SEATING CAPACITY FOR 1300 PEOPLE.

pincott Street, the length of the building north and south being 430 feet by 227 feet deep, and four storeys in height. The size of the site allows for the accommodation of a football field at the north end and tennis courts at the south end. The location of the school is in

Elaborate arrangements are provided for the comfort and convenience of teachers and pupils. Nine locker rooms, with 1,000 steel lockers; bicycle room for 400 bicycles; gymnasium, 90 ft. x 48 ft., with complete modern equipment; swimming pool, 50 ft. x 25 ft.,

The laboratories and shops, in which our readers are more directly interested, are mostly situated in the basement or Floor A, the principal exception being the chemical laboratories, which, for obvious reasons, are located in the upper floor.



TYPICAL CLASS ROOM.

PHYSICS LABORATORY.

the geographical centre of the city, and two main car lines, within a minute's walk, render it easy of access from all parts of the city.

The appearance of the building is decidedly imposing, the style of architecture being of Gothic character, while the exterior is of local limestone laid upon Scotch rubble masonry.

Three of the principal architectural features of the building are—the principal's office, which is also used as a board room, the library, and the auditorium, views of which are reproduced.

The auditorium is 80 feet broad and 90 feet long, consisting of a main floor and gallery. It has a seating capacity of almost thirteen hundred persons.

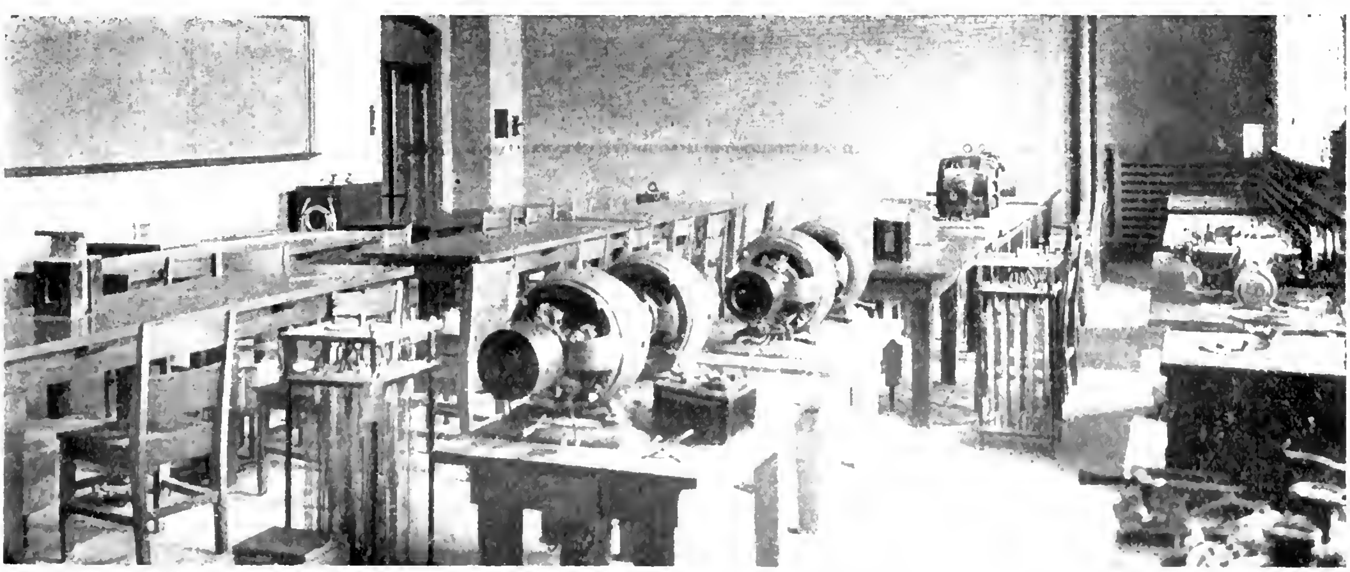
twenty-four showers, and forty dressing rooms, indicate to some extent the completeness of equipment in this respect. The provision of individual steel lockers is in line with the best modern practice, from the point of safety as well as hygiene. In common with most of the efficiency features of the building, these lockers were made in Canada, being the standard product of the Dennis Wire & Iron Works Co.

Thirty standard class rooms are provided, all being fitted with individual desks or tables and movable chairs. Cloak rooms, toilet rooms and assembly rooms, with the necessary offices, complete the equipment features of the institution.

Studies and Equipment

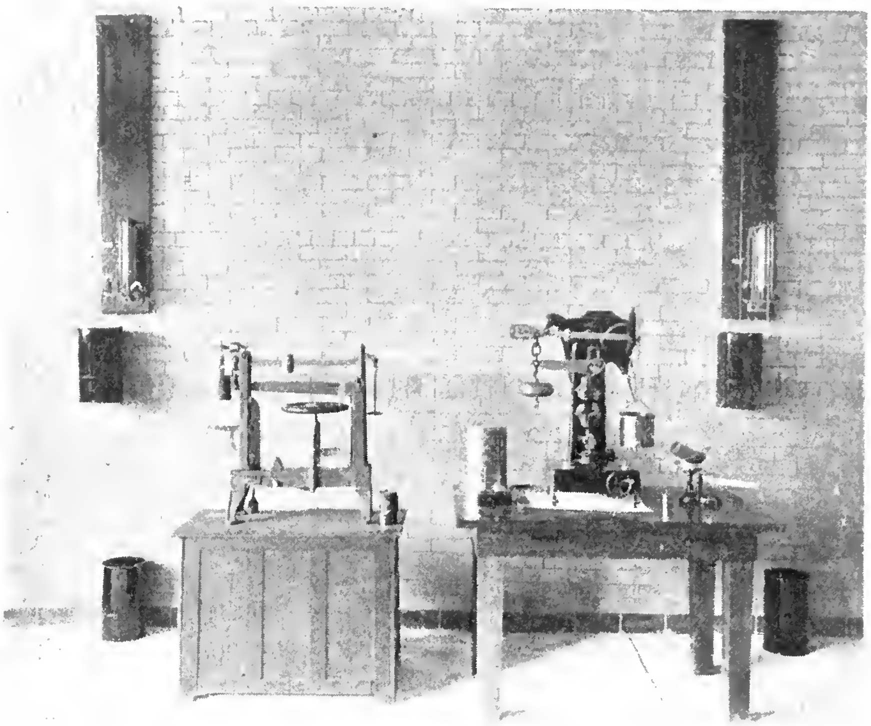
THE industrial course for boys and young men extends over a period of four years, and is designed to prepare them for the pursuits of industrial and commercial life. In general outline it is similar to the matriculation course, except that the latter portion is devoted to the attainment of practical knowledge and personal skill in the branch of industry which the student intends to follow; while in the matriculation course, the studies are directed to qualify the student for further intellectual development in the university.

The subjects covered by the industrial course include mathematics, physics, chemistry, mechanical drawing, freehand



DYNAMO AND MOTOR LABORATORY IN DEPARTMENT OF PHYSICS. COMPLETE EQUIPMENT IS INSTALLED FOR DEMONSTRATION AND EXPERIMENTAL WORK.

drawing, shop work, English, drill, gymnastic and swimming exercises; these studies being supplemented in the last year by such special subjects as geology



GROUP OF TESTING MACHINES IN APPLIED MECHANICS LABORATORY, DEPARTMENT OF PHYSICS.

and mineralogy, steam engine and power plant, architecture and building construction, estimating, clay modeling, printing — practical composition and press work; practical painting and decorating, metallurgy and assaying, and electro chemistry.

Of chief interest to engineers is the equipment provided for the study of physics, shop work, engineering and chemistry. These four subjects are of prime importance to the technical student, and the school authorities have shown their recognition of this fact in the liberal equipment provided for the study of these subjects.

Physical Laboratories

The study of physics forms part of all branches of the industrial course. It commences during the first year with electricity and magnetism, fluids and heat, with developments later in mechanics, heat, light, etc.

Four physical laboratories are provided on the main floor, two being equipped for general physics and two for special work in electricity and light. These rooms are all provided with special low-voltage direct currents, as well as with the usual alternating and direct currents.

Dynamo and Motor Laboratory

On the lower floor are installed the dynamo and motor laboratory and the applied mechanics laboratory. Amongst the principal articles of equipment in the former room are a Westinghouse testing transformer of 5 k.v.a. capacity, taking 110 volts primary, and providing 25-cycle secondary in steps of 200 volts up to a maximum of 12,000 volts; this apparatus is conveniently mounted on wheels so as to be available at any desired point; five ordinary transformers; two Westinghouse induction motors, both 5 horse-power, 3-phase machines for 25 and 60-cycle, 110 volt current respectively; one Swedish General Electric a.c. motor generator set, for 1, 2, and 3-phase alternating current, consisting of a 35 horse-power d.c. motor for 220 volts and 1,200 revs. per minute, and a generator having a capacity of 25 k.v.a., 60 cycles. It is arranged to deliver 116 amperes of 3-phase current at 125 volts, or 199 amperes at 72.5 volts, the 2-phase current being 119 amperes at 105 volts; two d.c. motor generator sets, by General Electric Co., are of 5 horse-power, having shunt wound motors running at 1,400 revs. per min., with 115 volts. A number of small motors and dynamos, of various types and sizes, are used for demonstrating principles of construction and design, while ample numbers of instruments are available for individual students. Three trenches run the full length of this room, and provide junction boxes for each table.

Applied Mechanics Laboratory

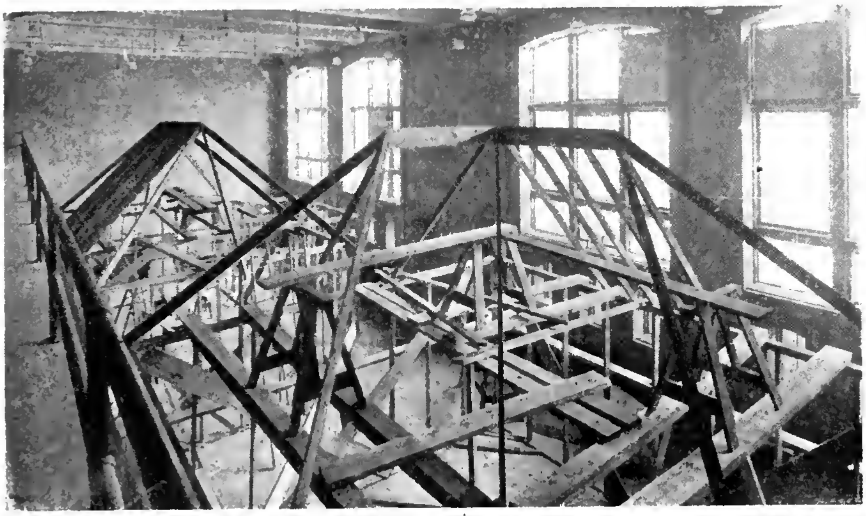
Connected with the dynamo and motor laboratory is the applied mechanics laboratory. The equipment of this laboratory includes an Olsen 30,000-lb. testing machine for tensile, transverse and compressive tests; one Olsen machine of 4,000 lbs. maximum load, for transverse tests only; a 300,000-lb. machine for compressive and transverse tests on brick and cement blocks; one Fairbanks tensile machine of 2,000 lbs. capacity and other appliances for cement testing; three Barr autographic recorders of stress-strain diagrams; various types of chain blocks, spring scales, etc., and ample equipment for the individual performance by the students of all minor experiments and tests.

During the third and fourth years the laboratory work in physics is strongly emphasized, and experimental work is carried on to a considerable extent, as shown by the following outline of the work. Third year electricity: dynamo

DEPARTMENT OF SHOPWORK. VIEW OF MILL ROOM IN WHICH LUMBER IS DRESSED AND CUT TO SIZE FOR USE IN WOODWORKING SHOPS.

and motor design, measurements and calculations of temperature rise of machines, efficiency tests, magneto motive force, magnetic flux and permeability, capacity of storage batteries, power and efficiency of lamps. Fourth year electricity: measurements and calculations of brake horse-power, insulation resistance and capacity of lines and condensers, magnetic flux and leakage in dynamo circuit, etc.; single and polyphase alternating currents, efficiency of transformers, induction and synchronous motors, etc.

In applied mechanics, the training is equally as thorough and complete, the same period covering the investigation of friction in various forms of mechanism, such as worm gears, jacks, pulley blocks, etc.; strength of materials, joints, properties of beams, columns, etc.; stresses in roofs and bridges, foundation work and reinforced concrete; also the flow of air, steam, and water in pipes, principles of fans, etc.



DEPARTMENT OF SHOPWORK. VIEW OF THE CONSTRUCTION ROOM WHERE STUDENTS IN THE BUILDING TRADES TEST THEIR SKILL ON A LARGE SCALE.

Department of Shop Work

THE value of a thorough training in shop work has long been recognized by the authorities, and the former equipment has been greatly enlarged and modernized to accord with present-day developments of machines and apparatus.

There are seven rooms devoted to instruction in woodworking alone, viz., two elementary shops, two pattern shops, one cabinet shop, one carpentry shop and one mill room. In addition to these, there is a construction room, 80 feet long, 37 feet wide, and 30 feet high, affording ample space for the erection of two moderate-sized dwelling houses at one time. Here the students of various trades are afforded facilities for performing their work under actual every-day conditions. Carpenters erect the framing, assemble interior finish, etc.; plasterers perform their work on selected parts of the building; paperhangers, wiremen, gasfitters and plumbers all receive opportunity for testing their ability to carry out the work of the various trades involved.

The equipment of the wood-working shops, where the various branches receive instruction, is very ample, and no expense has been spared to make the teaching truly individual. In each of the elementary woodworking shops there are six lathes, a trimmer, a mortiser, a jointer, a power saw, a tool grinder, and twenty-four benches with the usual small tools. One of the pattern shops has eleven lathes, trimmer, jointer, etc., and twenty benches. The other contains one 20-inch motor head block pattern-making lathe, with power feed, six 12-inch motor head block lathes, one band saw, one universal saw table, a jointer, a disc and spindle sander, a trimmer, twenty benches and small tools. The cabinet shop and carpentry shop are suitably equipped, while the mill room is furnished with a 30-inch cabinet surfacer, a 16-inch jointer, a rolling table cut-off saw, a self-feed rip saw, a band saw, a belt sander, a shaper, and a drying room, 11 ft. x 18 ft. x 14 ft.

Iron Working Shops

A foundry, forge and machine shop are equipped to provide individual instruction to students in classes of about twenty. The foundry is a lofty room, 57 ft. x 30 ft., containing a cupola, three brass furnaces, one core oven, a pneumatic rammer, moulding machines, a ladle heater, flasks and small tools. The photograph, reproduced on page 607, gives a good impression of the ideal conditions under which foundry students work. Comfortable, clean, well ventilated and well lighted surroundings, with the best of material and apparatus, enable the student to concentrate his attention entirely on the work. A row of wash bowls is installed on the gallery so that students may leave their work in comfort.

The work of the foundry class in the early stages consists of instruction in preparing simple molds and cores, followed by a study of the various materials, sands, binders, etc. As the work progresses in the other shops, more intricate patterns are received, while the use of molding machines and cupola charging are gradually introduced into the work. The preparation of brass castings, and work in non-ferrous alloys is also included in the regular work at later stages.

Forge

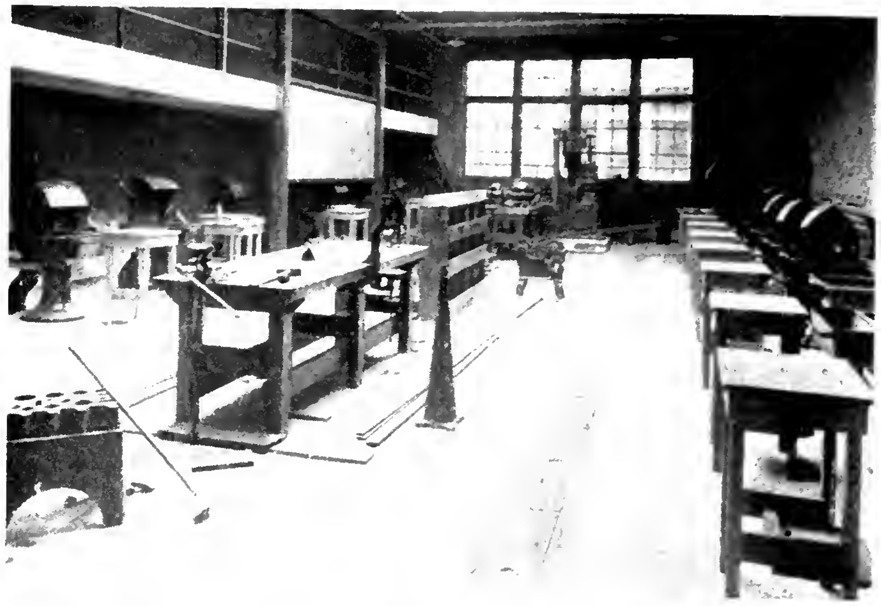
The equipment of the forge is representative of modern methods, including as it does twenty "Buffalo" down-draft

DEPARTMENT OF SHOPWORK. VIEW OF ELEMENTARY WOODWORK CLASS ROOM IN WHICH STUDENTS ARE TAUGHT TO HANDLE AND PERFORM SIMPLE MACHINE WORK.

forges, a gas heating forge and a gas-hardening furnace.

A complete Bristol pyrometer installation enables the effects of heat treatment to be fully investigated, the evils of careless heating being demonstrated in an impressive manner. The forging of tools for the machine shop, the making of dimensioned forgings, welding, hardening, tempering, etc., are a few of the activities pertaining to this department.

A hand lever shearing machine, and a medium size power hammer remove much of the physical effort from the work, and allow the student's time to be fully occupied in learning useful work rather than spending much of it in more or less useless exertion which is of no instructive value to him.



DEPARTMENT OF SHOPWORK. VIEW OF FORGE ROOM SHOWING SMITH'S HEARTHS, WITH POWER HAMMER AND HARDENING FURNACES IN BACKGROUND.

Machine Shop

The machine shop is 57 feet x 57 feet, and contains an ample equipment of plain engine lathes, with various other machines by representative makers. The room is light and airy. It is situated on the basement, and being in a court or well, it has been possible to provide ample daylight from the roof and also one side. Artificial lighting is very well taken care of by semi-indirect nitro-tungsten lamps.

Five motor driven tool-room lathes are installed. These are all driven by individual motors, the control systems used being General Electric and E. C. & M. Co. These lathes are fitted with taper and relieving attachments, and are well calculated to afford advanced pupils every facility for performing all operations likely to be encountered in everyday work. The makers of these machines are Reed-Prentice Co., Flather & Co., Lodge & Shipley Machine Tool Co., R. K. LeBlond Machine Tool Co., and W. P. Davis Machine Co.

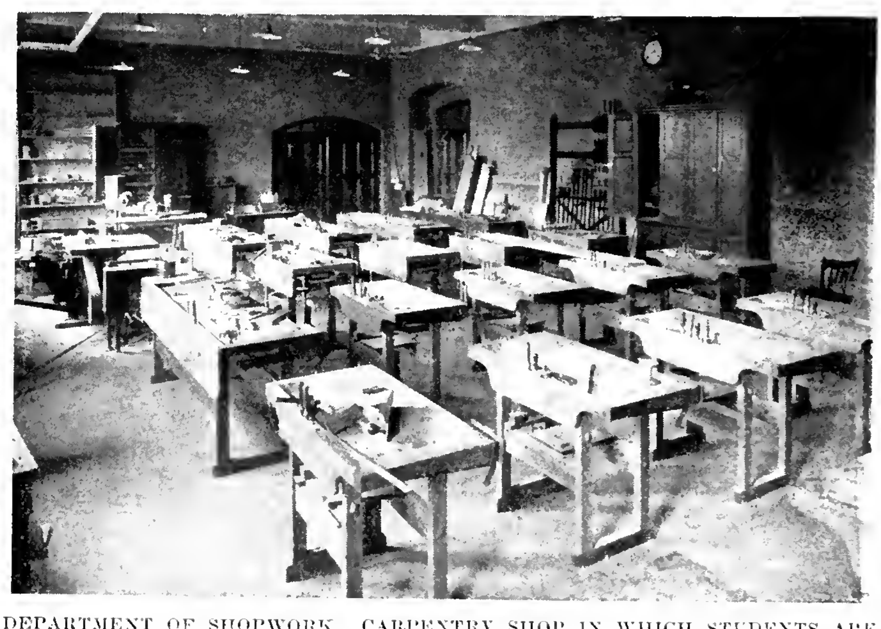
DEPARTMENT OF SHOPWORK. GROUP OF MOTOR HEAD WOODTURNING LATHES IN PATTERNMAKING SHOP.

Sixteen plain engine lathes of 14 in. capacity made by the Canada Machinery Corporation, are installed for class instruction in lathe work.

Milling machines include a motor driven No. 2 Cincinnati Plain Miller, one No. 1½ Brown & Sharpe Plain Miller, and two small universal Hendey machines.

A full equipment of shaping machines is provided including two "R. A. Kelly," one "Gould & Eberhardt," and one "R. McDougall." Other notable machines include one 26 in. x 26 in. x 6 ft. Bertram planer, with variable speed and reversing motor drive; one 10 in. x 36 in. plain Landis grinder; one Modern plain grinder; one universal and one cutter grinder by the Cincinnati Milling Machine Co.

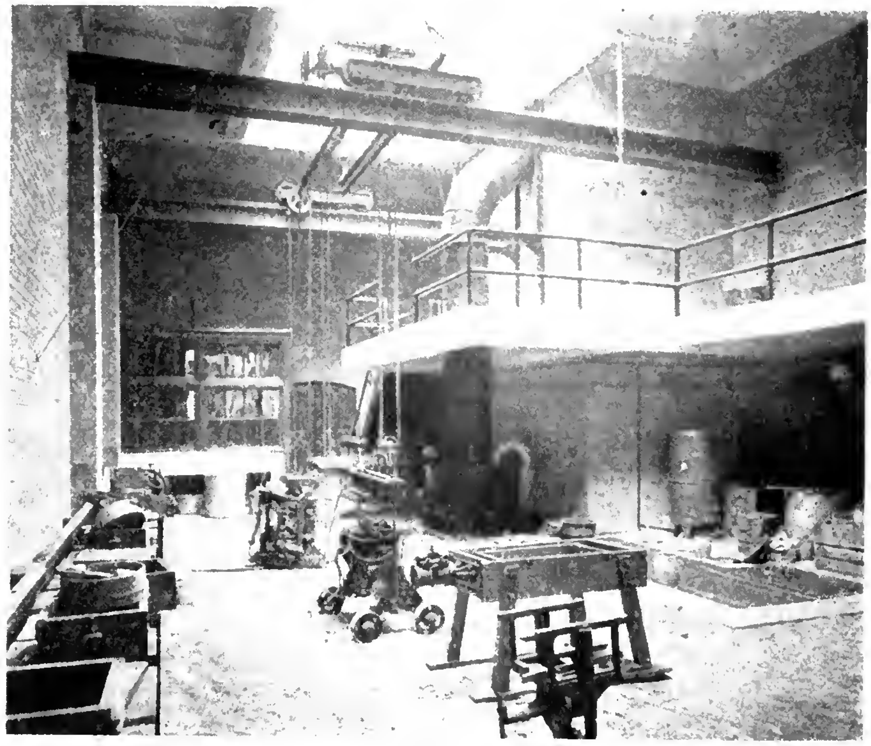
A No. 1 Colburn 12-inch heavy duty drill with individual motor and E. C. &



DEPARTMENT OF SHOPWORK. CARPENTRY SHOP IN WHICH STUDENTS ARE TRAINED TO BECOME EXPERT IN MANUAL WORK.

M. control; one Garvin die slotter; one C. M. C. power press and various accessory tools complete the equipment. All of the motor driven tools have Westinghouse motors, while ample bench capacity is provided for twenty students.

A feature of the small tool equipment is the provision of tool sets in individual racks, which is in accordance with most efficient shop practice.



DEPARTMENT OF SHOPWORK. VIEW OF FOUNDRY SHOWING CUPOLA, BRASS FURNACES, MOULDING MACHINES, AND WORK BENCH.

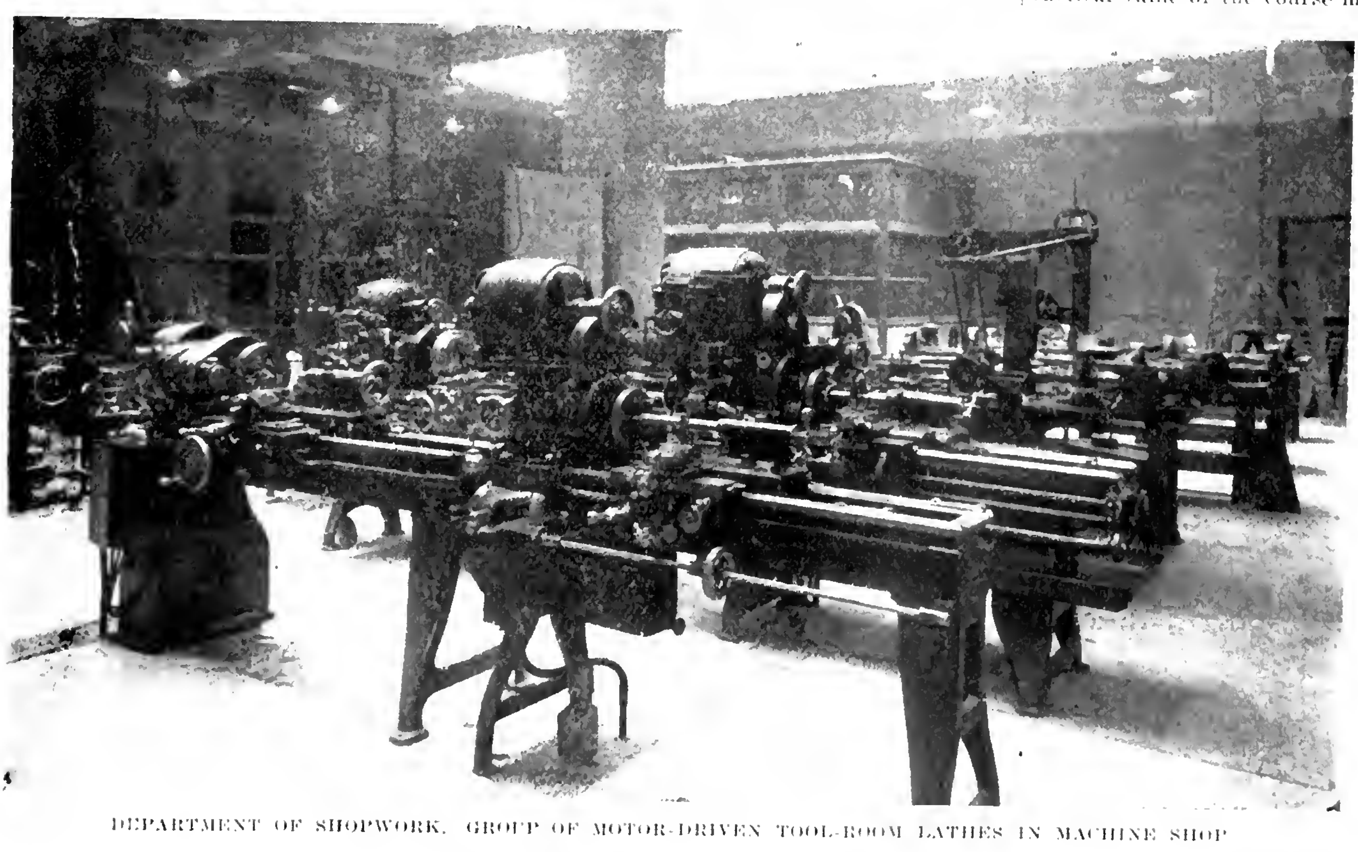
Printing Shop

Next to the machine shop equipment, that of the printing shop calls for comment. The great extent to which the art of printing contributes to the enjoyment of modern life, and facilitates the advancement of civilization in all parts of the world, is not always realized by the general public, probably because as the old saying puts it, "familiarity breeds indifference." and the ordinary newspaper is the most familiar object in these days. While newspaper work represents the more spectacular development of printing, the general publishing business employs thousands of persons whose ranks are being increased yearly.

Years ago conditions were such that at least some definite attention and instructions could be given beginners in the printing trade, and by the time apprentice days were over, the boy usually had acquired a good general working knowledge of the trade. On the other hand, the extensive improvements made in the operation of the printing business during the past decade, the tendency toward individual specialization, and other factors have limited the apprentice's opportunities for acquiring a knowledge of the craft.

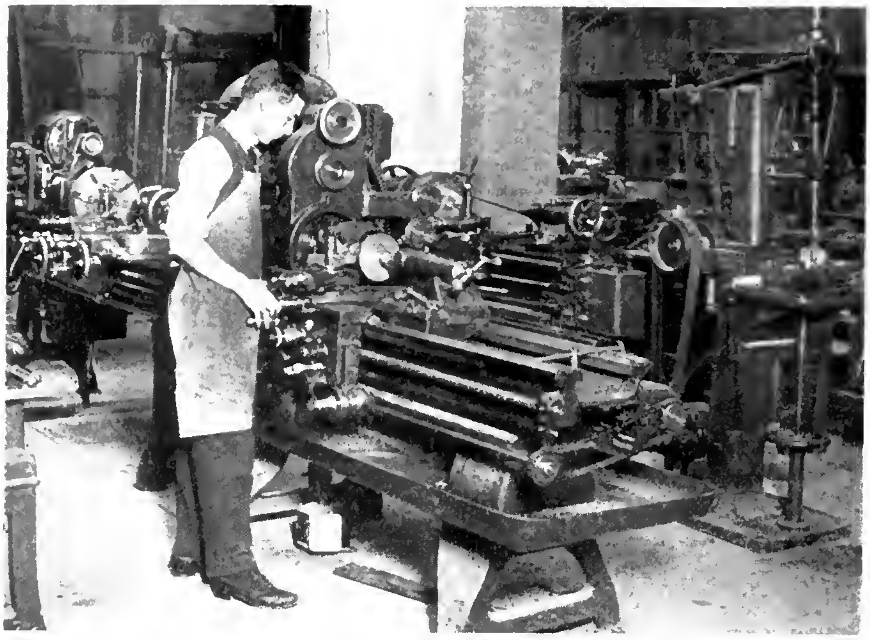
Three years ago the Toronto Board of Education took steps to assist the printer to secure this supply of human material by opening the Apprentices' School of Printing as a department of the Toronto Technical School. Their aim was not to relieve the printer of all responsibility so far as apprentices were concerned. Rather was it to accelerate the efforts of the printer and place at his disposal means whereby apprentices working at the trade can for certain periods of the week be under the personal guidance of a practical teacher.

A carefully selected equipment costing upwards of $15,000 has been placed at the disposal of the classes, and an idea of the practical value of the course may



DEPARTMENT OF SHOPWORK. GROUP OF MOTOR-DRIVEN TOOL-ROOM LATHES IN MACHINE SHOP

be gained from the rough summary of the lessons as follows: Practical work includes learning the case, setting of straight matter, tabular matter, letter-heads, billheads, menus, programs, title pages, advertisements, etc.; imposition of four, eight, twelve, sixteen, twenty-four and thirty-two page forms; folding machine work, platen and cylinder press work and make-ready are also included in this course.



DEPARTMENT OF SHOPWORK. ONE OF THE ELECTRICALLY OPERATED LATHES IN MACHINE SHOP ON WHICH STUDENTS PERFORM INTRICATE OPERATIONS.

Free-hand drawing and lettering design and harmony, and a section on English complete the curriculum.

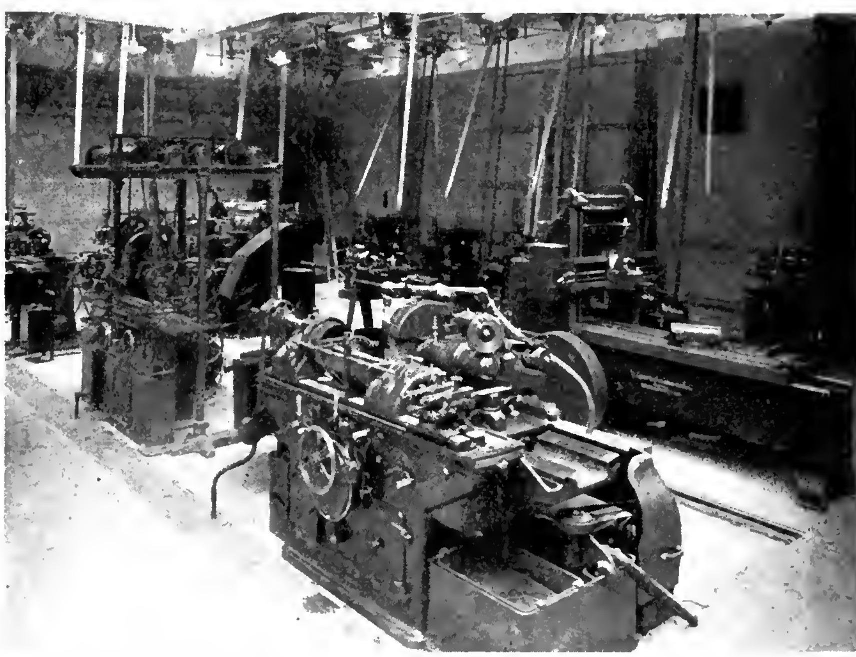
The composing room is 48 ft. x 33 ft. with large window areas on the north and west. It is equipped with thirteen Tracey cabinets, eighteen type racks, and a large steel top imposing stone.

The press room is 56 ft. x 28 ft., and contains a No. 3 Miehle press, a Colts Armory press, a Phoenix press, a 38 in. automatic power paper cutter, a hand paper cutter, a folding machine, and two wire stitchers.

Building Trades

Included in the above category are shops devoted to instruction in Plumbing and Steamfitting, Electrical Construction; Brickmaking and Bricklaying: Cement and Stone Work, and Plaster Decoration.

Through the kindness of interested firms, the brick department is equipped with a pug mill, a soft-mud machine and a stiff-mud machine, the latter having a wire cut table. The other trades mentioned are well taken care of so far as instruction and equipment is concerned, all modern tools and apparatus being on hand. The final test, of course, is trying out the students under practical conditions, and it is in connection with this that the value of the construction room becomes so evident. The present stage of construction includes the erection of frame dwellings and each of the building trades classes is afforded opportunity of carrying out the work under actual house-building conditions. Plumbing, wiring, plastering, wallpapering and all decoration work is performed on a suitable scale so that maximum instruction is given on each subject.



DEPARTMENT OF SHOPWORK. VIEW OF MACHINE SHOP, SHOWING GRINDING MACHINES, REVERSING MOTOR PLANING MACHINE, AND SHAPERS IN BACKGROUND.

In the near future it is intended to make a more complete effort in which the work will be a two-storeyed brick building, the bricks being made in the school shop and laid by the school class.

Architecture and Design

The theoretical side of building and machine work is well taken care. Four class rooms are assigned to the architectural classes and four to the mechanical classes. One of the former, devoted to the teaching of elementary architecture, contains forty-five individual drafting tables. The mechanical rooms are also furnished with individual tables, all of the rooms being provided with a universal blackboard drafting machine. Blueprint rooms are situated on the roof of the building and are equipped with a continuous printing machine, while frames for sun printing are also supplied.

Department of Chemistry

THE chemical department includes seven distinct laboratories for the following special purposes, viz.: Elementary Chemistry, having working accommodation for sixty students and locker accommodation for five hundred students; Industrial Chemistry, provided with three fume closets, working tables and lockers for forty students, and special apparatus for various trades; Qualitative Chemistry, fitted up with special drafts, and a large fume closet for the hydrogen sulphide generator. There are working places for forty students; Qualitative Chemistry, accommodating forty students and provided with fume closets, D.C. and A.C. current, compressed air, steam and drying ovens; Electroplating, provided with a motor-generator to produce low voltage currents suitable for electroplating, ammeters, voltmeters, tanks, etc.; Metallurgy, furnished with

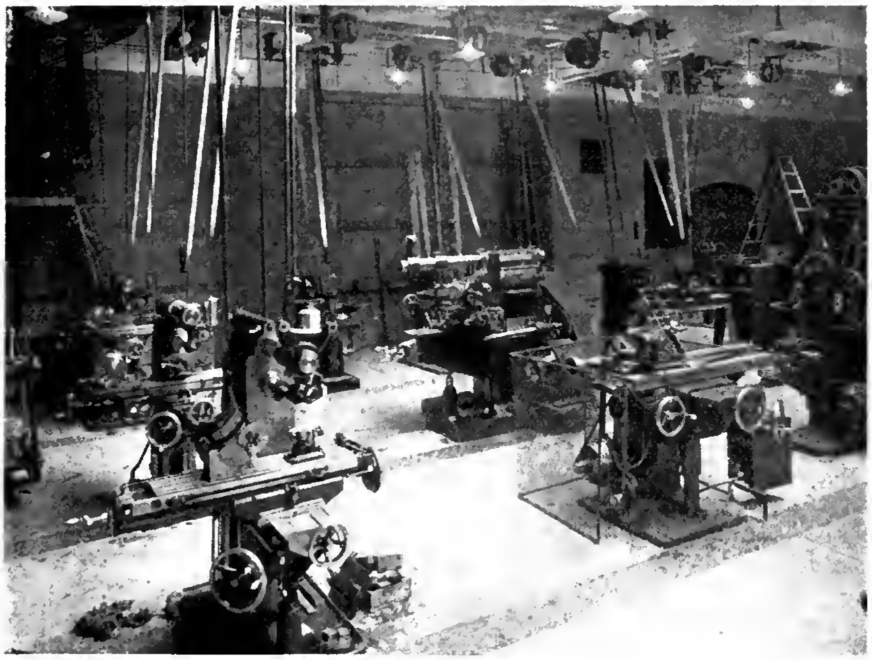
various types of furnaces for use in assaying and the study of metallurgical operations; Photography and Photo-engraving, consisting of a large dark-room with working space for twenty students. Individual sinks with ventilating hoods and ruby lights, and a smaller dark cabinet are features of the equipment.

A feature of the work of the department is the provision of special evening trades classes for workmen who desire to obtain instruction in specially advanced or peculiar applications which they have no opportunity of studying during their regular work.

Electro-plating and dye-work are two of the industries which are receiving special attention in this manner, and it is intended in the near future to either investigate special problems for such manufacturers as desire it, or arrange to place the equipment at their disposal. In this way the work of the department will gradually come more into contact with actual commercial work, and the judicious direction of students' energies may well ultimately result in the general advancement of the various industries concerned, not so much through special assistance on specific cases, as in the increased skill and knowledge of the operatives.

Work in geology and mineralogy is provided for those who are interested in the application of the earth's products to industry and art, and for all who may be interested in the pure sciences.

The importance of chemistry in household work is not overlooked, and it occupies a suitable place in the course of Domestic Science for young women.



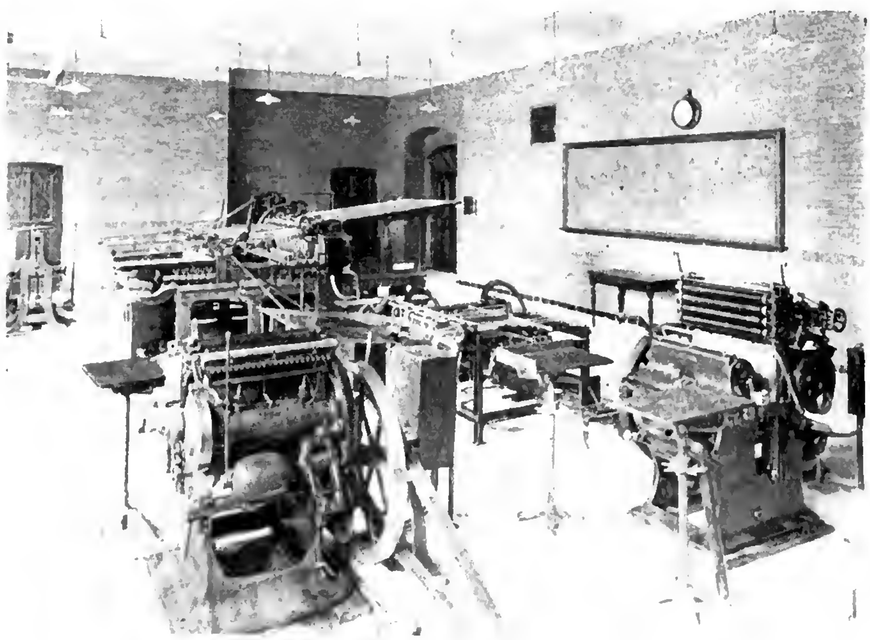
DEPARTMENT OF SHOPWORK. GROUP OF MILLING MACHINES IN MACHINE SHOP.

Power, Light and Heat

THE engineering department of the new Toronto Technical School comprises the entire power plant, heating and ventilating system, air compressor plant, refrigeration plant, elevators, hot water service system, the various auxiliaries and the experimental engine laboratory. The engineering department is one of the most important in any technical school and in this case no expense has been spared in getting the best equipment and installing it to the best possible advantage to meet the requirements of an institution of the kind. The power plant, for instance, in addition to furnishing light, heat, etc., for the building, can also be turned to good account for the benefit of the students, although primarily it is intended for the former service.

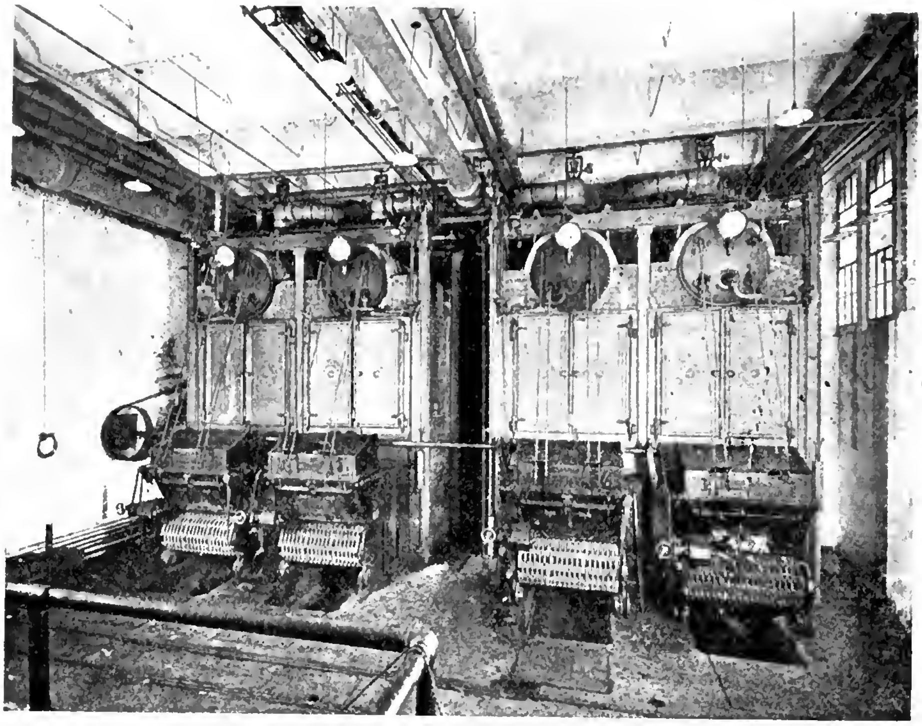
The various requirements that had to be considered in the layout of the plant may be briefly summarized as follows: To provide light, heat and power for both day and night use independent of outside power, but at the same time to operate in conjunction with it if necessary; to include in the plant such an assortment of equipment and apparatus as to give the student an opportunity of familiarizing himself with various makes and designs which he might encounter in his future career; to distribute and supply electricity, compressed air, hot and cold water, to all the shops and laboratories for the benefit of the students; to provide good heating and ventilation and an adequate supply of hot and cold water for the lavatories and swimming tank; to have a plant that could be used for demonstration purposes for students, and at the same time used for ordinary purposes without any loss of efficiency.

The power plant is located in the sub-basement 25 feet below the basement floor, and 30 feet below the street level. The sub-basement floor is 16 feet below the sewer, and is divided into three main sections, boiler room, engine room and fan room. The boiler room is again subdivided to form the pump room at a slightly higher level. In the boiler room in addition to the boilers are the sump pit, coal bunkers and blow-down tanks.



COMPOSING AND PRESS ROOM, WHERE STUDENTS ARE TAUGHT THE VARIOUS BRANCHES OF PRINTING

In the pump room are the boiler-feed pumps, circulating pumps on the heating system, feed water heater, live and exhaust steam heaters, service water heater, swimming pool water heater, and filter.



WATER TUBE BOILER INSTALLATION.

The engine room contains a large high-speed engine and generator, a horizontal high-speed unit, a horizontal "Corliss" engine and generator, air compressor, ammonia compressor and motor generator set. On the gallery is the switchboard, while on the same level, but outside the engine room are the operating engineers' room, locker and lunch room for the firemen, several store-rooms shower bath and lavatory. In a small room off the engine room and at the same level is a transformer room and also the refrigerator room containing a tank for making can ice, also drinking water chill and filter. In the fan room are two large ventilating fans with air washers and heaters, a smaller fan for the smith-shop forges, vacuum machine for the chemical and physical laboratories, a vacuum cleaning machine, and temperature regulator equipment. On this floor leading to the fans is a large cold air intake 10 feet high by 25 feet wide.

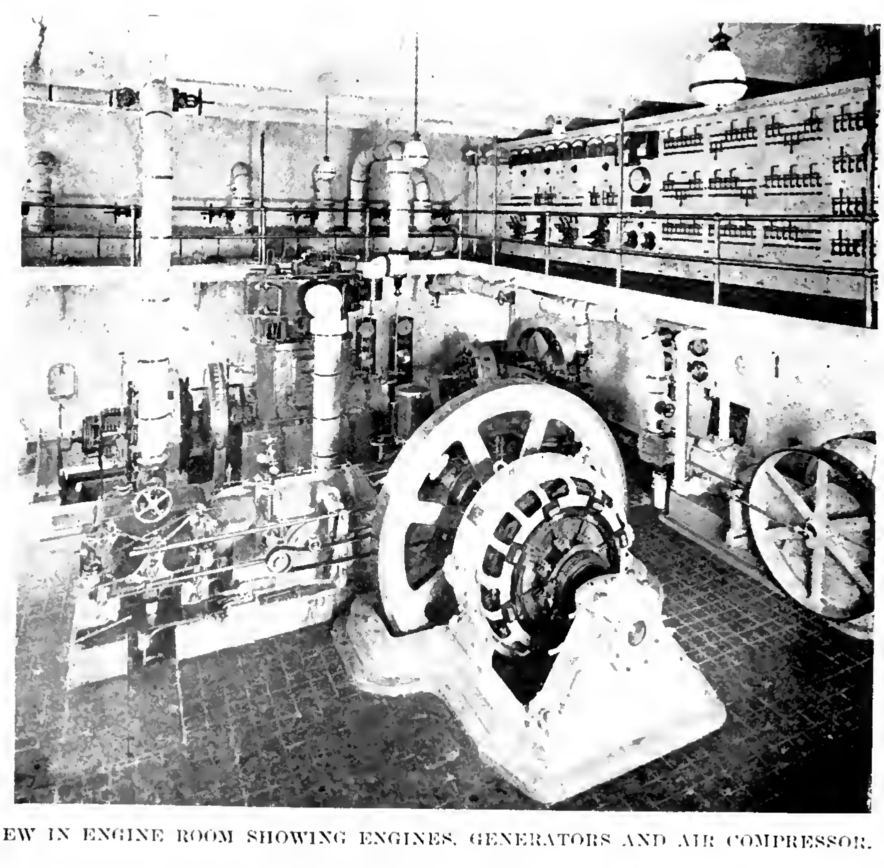
Boiler Installation

The boiler plant consists of four water-tube boilers, arranged in two batteries and having a total horse-power of 720. Each boiler is rated at 180 horse-power, and has a heating surface of 1790 sq. feet. The tubes are 4 in. in diameter and 18 ft. long, arranged in 8-sections wide, and 10-tubes high. Each boiler has one steam drum 42 in. diameter. The boilers are of standard forged steel construction and are built for a working pressure of 200 pounds, but are operated at 150 pounds per sq. inch. They are fitted with superheaters to give 100 to 120 degrees Fahr., and have chain-grate stokers each having a grate area of 35 sq. ft. The boilers and chain-grates were built and installed by the Babcock & Wilcox Co., Montreal and Toronto.

The boilers are suspended from steel girders resting on steel columns on cast iron bases. The flue dampers are operated by hand. The boilers are fitted with B. & W. type mixing valves, by which the temperature of the superheated steam may be controlled. They are also fitted with standard thermometer wells in superheat box. Auxiliary wells are installed in the steam line with steel mercury thermometers having gauges in front of the boiler giving reading of steam and superheat. Each boiler has two 2½-in. McAvity pop safety valves, one 12-in. brass cased steam gauge, one "Turnbull" high and low water alarm, two ¾-in. water gauges fitted with automatic closing valves, one 2-in. diameter stop and check valve, one 2-in. diameter stop valve, etc.

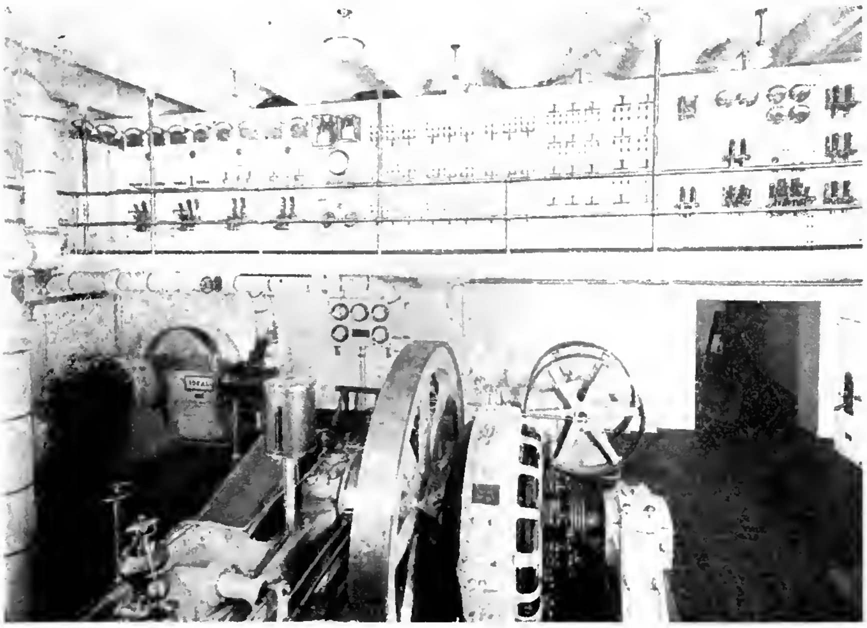
Coal is fed to the grates through hoppers in front of the boilers. Each hopper is provided with a valve for shutting off the supply of coal to the fire and thus controlling the depth of the latter. Doors are provided at the front of the hoppers for hand firing. The stokers are operated by a standard B. & W. vertical enclosed 5½-in. x 5-in. engine, and the coal is carried to the hoppers in a car running on tracks and having a capacity of 1,000 pounds. The coal bunkers are at the side of the boiler room under the sidewalk level. The coal is weighed on a "Dormant" warehouse scale having a capacity of 2,500 pounds and supplied by the Canadian Fairbanks-Morse Co.

Two duplex 7½-in. x 5-in. x 6-in. outside packed plunger pumps, fitted with pot valves, are installed for feeding the



VIEW IN ENGINE ROOM SHOWING ENGINES, GENERATORS AND AIR COMPRESSOR.

boilers. The pumps take water from the "Cochrane" heater to the boilers, and were supplied by the Smart-Turner Co., Hamilton, Ont. For emergency use there is installed a "Metropolitan" injector, single level pattern. The injector is fitted with a by-pass, so that city water can be used direct.



ANOTHER VIEW IN ENGINE ROOM SHOWING HORIZONTAL CORLISS ENGINE AND GENERATOR IN FOREGROUND.

The "Cochrane" feed-water heater is rated at 750 h.p., its exhaust inlet and outlet being 12 in. diameter. The heater is fitted with five gravity return connections from exhaust steam heating system. It has a 6-in. connection for boiler feed and a 3-in. connection for discharging from traps. A pump and receiver are installed for collecting condensate from the live steam heater and returning same to the boilers. The pump is a 6-in. x 4-in. x 7-in. duplex type of "Smart-Turner" make. The outfit is equipped with a "Waters" type of governor valve and float, and water at 250 degrees can be handled. Two "Davis" 5 in. automatic stop and check-valves are fitted in the steam headers, one for the main engines and one for the auxiliary units.

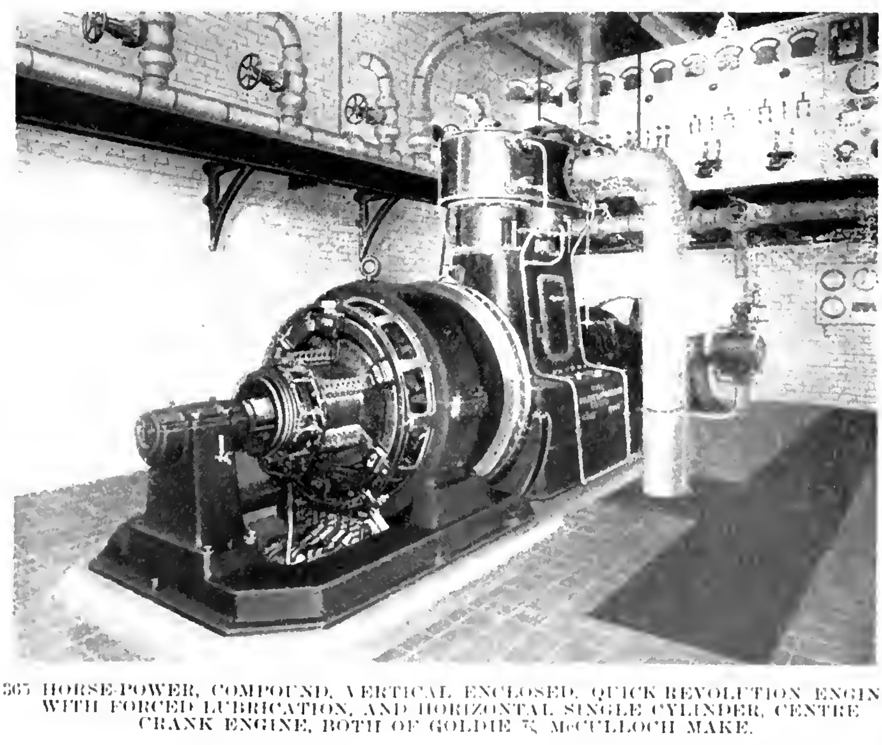
The boiler blow-down tank is located at the rear of the boilers. It is 36 in. in diameter and 48 in. deep, with a 4-in. connection to the boilers and also to the sewer. A 4-in. vapor tube is connected to the tank. This tube leads from the exhaust pipe and allows the steam or vapor to go from the tank to the heating system and also drains water from the steam-line. The exhaust steam main is 12 in. diameter and the main water-line for the heating system is 10 in. diameter.

There are a number of steam traps installed; one "Davis" trap drains the steam headers and all steam heating coils for laundry and dry kilns. A "Davis" trap is also fitted to the service water heater, and the steam connections in the chemistry and physics laboratories are fitted with similar traps. The swimming pool heater is fitted with a trap. All high-pressure traps discharge to the feed water heater, and the exhaust pipe traps discharge to the sump through the blow-off tank.

Engine Room

The engine room has a bright and attractive appearance, the area occupied being 43 feet by 40 feet, and height of ceiling 20 feet. The flooring is of red Welsh tiling, and the side walls of white tile with white enamel finish above; a large mezzanine balcony accommodates the switchboard, and quarters for the engineers lead from same. The units installed are of different types and were selected to show the students the various kinds of machines in use at the present time. The steam plant is more than large enough to develop the necessary power for the motors and lighting systems, etc., but a very favorable rate was obtained from the Toronto Hydro-Electric Commission, so power from this source is largely used. The fact that the plant is larger than absolutely necessary for the power required is accounted for by the necessity of having the various units for demonstration purposes as well as for the actual development of power for the building.

The largest unit is a high-speed compound vertical enclosed, forced lubrication-engine built by the Goldie & McCulloch Co., Galt, Ont. This engine is rated at 365 h.p., and has cylinders 16 in. and 25 in. diameter, by 10 in. stroke. The governor is of the combined throttling and cut-off type. The engine runs non-condensing and is specially designed for superheated steam. The cranks are set opposite to one another, and the reciprocating parts of the high and low pressure sides are carefully checked so that they weigh exactly the same. This arrangement practically balances the reciprocating parts and eliminates vibration at high rotative speed. The engine is direct connected on a common subbase to a 250 k.w. three-wire d.c., inter-



365 HORSE-POWER, COMPOUND, VERTICAL ENCLOSED, QUICK REVOLUTION ENGINE WITH FORCED LUBRICATION, AND HORIZONTAL SINGLE CYLINDER, CENTRE CRANK ENGINE, BOTH OF GOLDIE & McCULLOCH MAKE.

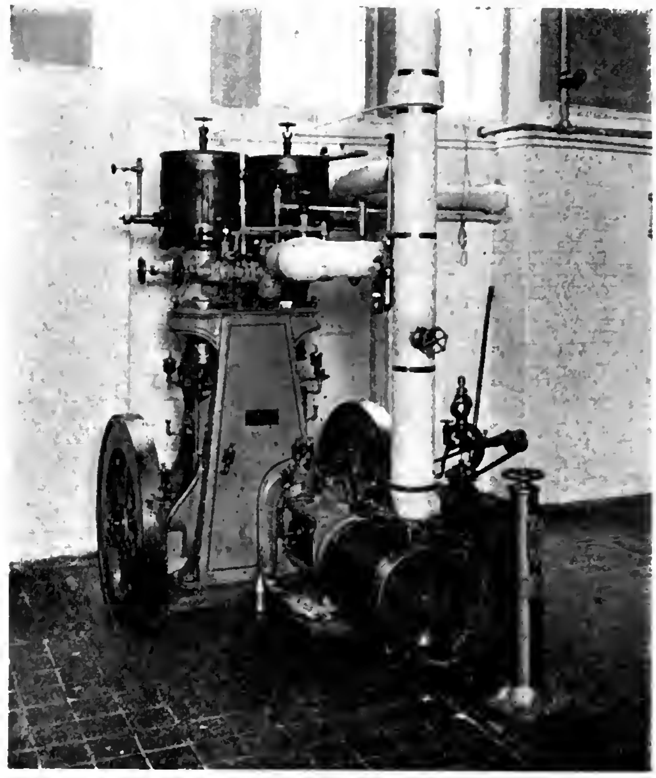
pole generator, built by the Canadian Westinghouse Co.

There is also a horizontal double eccentric Corliss engine built by the John Inglis Co., Toronto, Ont. The engine has steam dash pots, is rated at 150 horsepower, and has a cylinder 12 in. diameter by 24 in. stroke. It is direct connected to a 100 k.w., three-wire interpole d.c. generator built by the Canadian Westinghouse Co., Hamilton. The speed is 150 revolutions per minute. A smaller unit showing a type in common use consists of a single cylinder Goldie & McCulloch centre crank 10 in. x 12 in. "Ideal" engine. This runs under the same steam conditions as the other units and is rated at 75 horse-power, when running at 275 r.p.m. It is of the enclosed type with splash oil system, and is direct connected to a Canadian Westinghouse Co. 50 k.w. three-wire d.c. generator.

For converting hydro a.c. current to d.c., which is used throughout the building, a Canadian Westinghouse Co. motor generator set is installed. This unit consists of a 125 h.p. three-phase 550 volt. induction motor direct connected to a three-wire d.c., 110-230 volt, 3-wire generator with a capacity of 75 k.w., and running at 800 r.p.m. The starting mechanism for the motor generator is of Canadian Westinghouse Co. make, and is mounted on a white marble panel with an oil immersed auto-switch.

Compressed air for the shops and laboratories and for general use about the plant is supplied by an air compressor built by the Canadian Ingersoll Rand Co., Sherbrooke, Que. This compressor is a 10-in. x 10-in. x 14-in. straight line steam driven machine. It delivers 230 cubic ft. of free air per minute at 100 lbs. per sq. inch, when running at 180 r.p.m. The machine is fitted with an automatic regulator which can be adjusted to obtain any desired pressure. An interesting and somewhat unusual purpose this air compressor is put to is for the swimming pool. Air is blown up through the water in the pool, thus aerating it and driving any scum on top to the channel around the side. The air receiver is 36 in. in diameter, and 72 in. high.

An ice machine is installed in connection with the refrigerator in the Domestic Science Department, for making can ice and for chilling the water supply to the drinking fountains. The ammonia machine has a capacity of 12 tons, and was built by the Frick Co., Waynesboro, Pa. It is a vertical two-cylinder machine, and is direct connected to and driven by a single cylinder horizontal steam engine with "Merze" valve gear. Calcium chloride brine is used, being circulated through the system by a centrifugal pump supplied by the Smart-Turner Co., Hamilton, Ont. The water cooling and can ice plants are in a small room adjoining the engine room. The can ice plant has a capacity of 200 pounds at one pumping.



SINGLE-ACTING VERTICAL AMMONIA COMPRESSOR, DIRECT CONNECTED TO HORIZONTAL ENGINE.

Two Venturi meters are installed in the engine room of 3 in. and 10 in. sizes respectively. The former measures the water being used by the boilers and the 10-in. meter measures the water used in the heating system. The majority of the lubricators used in the plant were furnished by the Canadian Detroit Lubricator Co., Walkerville, Ont. The forced feed lubricator on the large Goldie & McCulloch engine was furnished by the McLeod Mfg. Co., Detroit, Mich. The covering for the high pressure pipes was supplied by the Canadian Asbestos Co., Montreal, Que., and is composed of 85 p.c. magnesia, and sectional, in two thickness. Over this is a layer of 8 lb. sheathing paper, and over that again is a covering of 8 oz. canvas. The pipe fittings are covered with 85 p. c. plastic magnesia and the flange joints with removable hinged covers to facilitate inspection. An oil separator is installed in the main exhaust pipe near the "Cochrane" heater.

A 12-in. "Swartwout" exhaust head is fitted to the exhaust stack. It is of cast iron and is fitted with a 2½ in. drain. A 12-in. "Davis" automatic com-

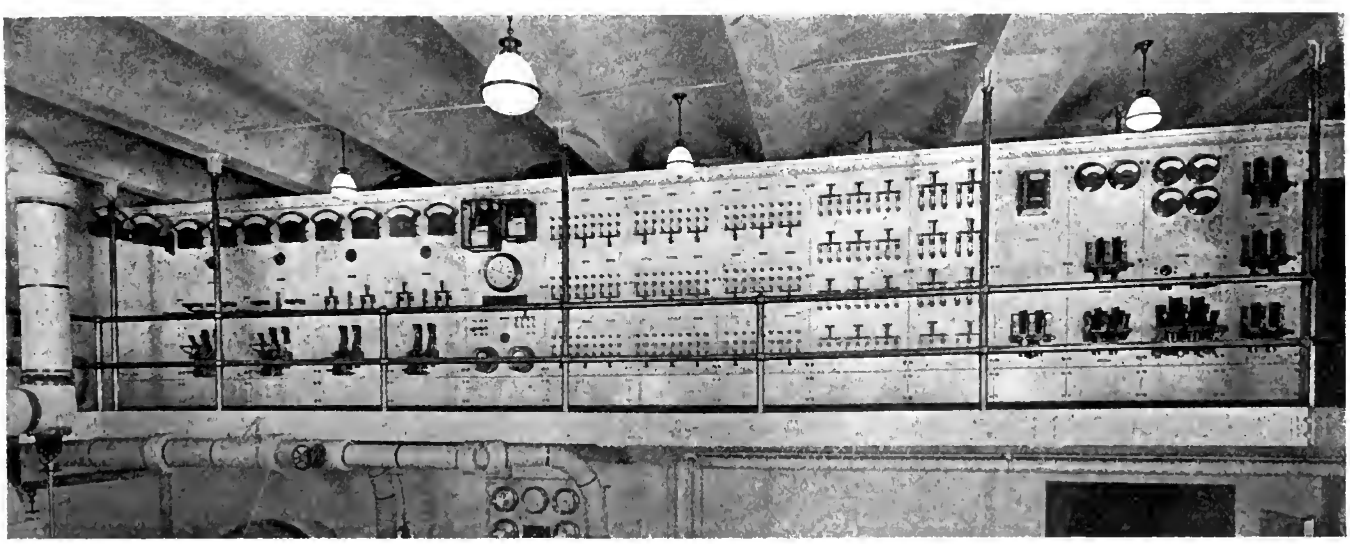
GENERAL VIEW IN PUMP ROOM.

bination back pressure and relief valve is fitted in the base of the exhaust steam stack. A "Simmance-Abdy combustion recorder is installed in the engine room. This apparatus is for testing flue gases and was supplied by the Precision Instrument Co., Detroit, Mich. The steam valves are of "Jenkins," "Chapman," and "Lunkenheimer" make. All the steam and hot water piping was supplied and erected by the General Fire Extinguisher Co., Toronto.

Switchboard

The main switchboard, which is an exceptionally fine piece of work is situated on a balcony along one side of the engine room. It was designed by the Canadian Domestic Engineering Co., Toronto, and installed by Keith's, Ltd., Toronto. The switchboard is 42 feet by 8 feet, and was designed to control 3-engine driven generators, one motor generator set and feeder circuits for light and power, both a.c. and d.c. The system is 120 volts d.c., and 3-wire, 550 volts 3-phase, 25 cycles for the a.c. service and branches.

There are 17 panels, Nos. 1 to 11 being for d.c., and 12 to 16 for a.c. service, and one totalling panel. The panels are made of white Italian marble 2 in. thick, each being built in two sections and supported on an angle iron frame work. There are two sets of bus bars, one carrying the current from the generators which are arranged with equalizer connections so that they can be run in parallel. The other set of bus bars carries the current from the motor generator set serving all the lighting and such power as may be required when the engines are not running. Double throw-switches are installed for this service.



17-PANEL MAIN SWITCHBOARD DESIGNED BY THE CANADIAN DOMESTIC ENGINEERING CO., AND INSTALLED BY KEITH'S, LTD., TORONTO.

There are four generator panels, each being equipped with I.T.E. double pole circuit breakers, a single pole knife switch for the neutral wire and a double pole single throw knife switch for the power wire. Each panel has two "Weston" ammeters and a field rheostat for controlling the voltage of the generators. The totalling panel in the centre of the board has one d.c. graphic recording "Westinghouse" meter for all the generators; one d.c. graphic recording "Westinghouse" watt meter for the motor generator set, and a clock which is connected with the clock system. There is also on this panel an integrating watt-hour meter, also "Westinghouse Columbia" type, 3-wire service for the motor generators. One rotary volt-meter switch is arranged so that the total voltage of any generator can be obtained, or voltage of either outside line and grounded neutral. There are two volt-meters mounted on a swing bracket at the end of the board. One is a single scale instrument connected to the bus bars, and the other a double scale instrument connected to the generators.

There are three light-distributing panels, each having nine triple pole, double throw knife switches. There are also two power-distributing panels. One of the latter has nine single throw triple pole switches and three double throw triple pole switches. The double throw switches control the elevators, machine shop, and some sections of the wood-working shop, so that these can be run by the motor generator or engines. The other power distribution panel has six single throw, triple pole, knife switches and two double throw, triple pole, knife switches.

There are five a.c. service panels. One panel has a three-pole, single throw disconnecting knife switch at the back of the board for controlling the a.c. service. It has also a "Thompson" polyphase meter, and one "I.T.E." circuit breaker. The next a.c. service panel is for the motor generator. It has two "Weston" polyphase watt-meters of 30 k.w. and 100 k.w. respectively, and two "I.T.E." circuit breakers. Another a.c. panel is the frequency changer panel. This has a "Weston" a.c. ammeter, and ammeter receptacles for reading currents in any phase; one "Weston" ammeter for a.c. field; one "Weston" frequency meter, and a "Weston" volt meter. This panel has also a double pole single throw switch with discharge clips and resistance: a rheostat mounting, an eight-point potential receptacle with 4-point plug, and one 3-way ammeter switch on "I.T.E." circuit breaker.

Another a.c. distribution panel has three "I.T.E." circuit breakers. The circuit breakers are used instead of switches for a.c. distribution from the switchboard. All switches are provided with enclosed cartridge fuses, and all current carrying parts are of polished copper.

Heating System

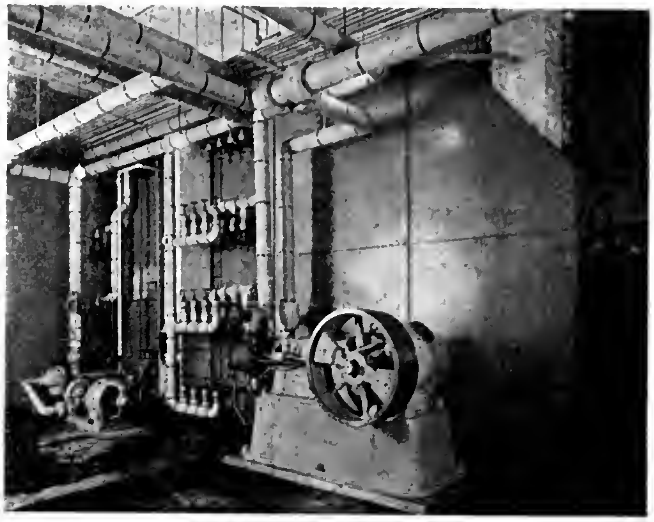
The heating system is an interesting feature of the plant, the principle adopted being hot water heating with forced circulation. The water is first warmed in large heaters and then made to circulate through the radiators by means of centrifugal pumps, afterwards being returned through the heaters with a small loss of temperature. The heaters and pumps are located in the pump room where are also the various return mains all under direct control of the operators. Exhaust steam from the engines and pumps is used in the heater, and afterward returned to the boilers through oil filters.

The exhaust steam heater is 14 ft. 8 in. long overall and 64 in. diameter inside. It is composed of a steel shell, cast iron inlet and outlet chambers, and removable tube cover chamber fitted with a 10 in. nozzle for water connection. The heater contains 1,080 one-

inch brass tubes and has a 2-in. diam. connection. There is in addition a live steam heater which can be used to automatically supplement the exhaust steam as needed. The live steam heater is of a similar construction as the other, but is rather smaller, being 14 ft. 8 in. long over all and 49 in. diameter. It contains 640 one-inch brass tubes and is tested to 200 pounds per sq. inch. The steam passes through, and in passing condenses, transmitting its heat to the water being pumped through the heating system. The heaters were supplied by the General Fire Extinguisher Co.

In this system the temperature of water circulated can be maintained either above or below boiling point, it also can be regulated or controlled at the heaters, thus making it possible to vary the temperature of water to suit climatic conditions. Water can be transmitted any required distance with uniform velocity and small temperature loss. The combined capacity of the heaters is sufficient to carry over 250,-000 feet of radiation.

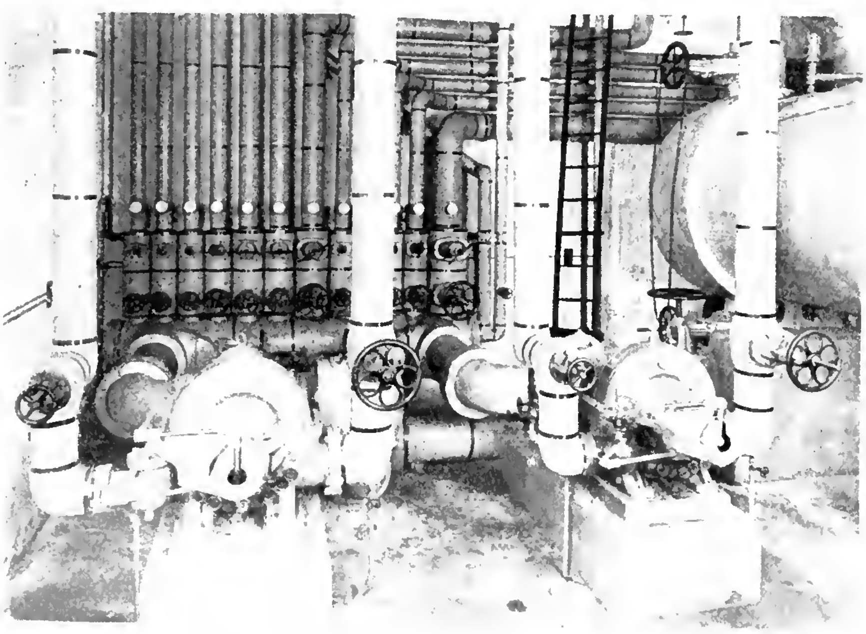
There are two pumps both of the same type for circulating the water through the building. Each pump is of the single stage centrifugal type; having a capacity of 2,100 gallons per minute against a head of 80 feet. The pumps have 10 in. inlet and outlet connections and run at 1,850 r.p.m. They have horizontal split castings giving easy access to all moving parts. Each pump is direct connected by means of a flexible coupling to a single stage, impulse steam turbine, mounted on same sub-base on concrete foundations. The pumps are provided with a 1 in. by-pass valve for operating at slow speeds, and are connected to the heating system separately, so that either unit can be operated independently as desired. The pumps and turbines are of the "De Laval" type and were supplied by the Turbine Equipment Co., Toronto. The heating system was installed by the General Fire Extinguisher Co., Toronto.



FAN ROOM, SHOWING VENTILATING EQUIPMENT.

Ventilating System

The ventilating system is of the plenum type, the building being divided into two sections, each having its own fan and air washer, etc. Approximately 180,000 cubic feet of air is supplied per minute, warmed to 70 degrees Fah., washed, purified, humidified and passed through over five miles of galvanized iron ducts. The two large fans installed in the sub-basement are of the "Keith" type, and were supplied by Sheldons, Ltd., Galt, Ont. Each fan is of double width and full housed, with 70 in. diameter wheel. There are two inlets each 72 in. diameter and the outlet is 60 in. by 90 in. The capacity is 90,000 cubic ft. of air per minute when running at 180 r.p.m. Each fan is driven by a 12-in. x 12-in. horizontal central crank engine built by Sheldons, Ltd., Galt.



FORCED HOT WATER HEATING EQUIPMENT.

The air washing and humidifying apparatus was supplied by the Carrier Air Distributing Co. of America, New York. The primary heaters of the "vento" type are arranged in two groups, each three sections high and 34 wide, each section containing 13.5 sq. ft. of radiating surface. The tempering coil is made up of two and three heating coils of four banks deep, therefore the primary heater consists of tempering and reheating coils and is made up of six banks containing a total of 16,524 sq. ft. There are also six supplementary heaters each arranged in two banks of nine 60-in. sections or 8-in. centres. The total surface per heater is 198 sq. ft. or 1,188 sq. ft. in the six supplementary heaters.

Each of the above installations is provided with a damper which automatically controls the air flowing to the primary heaters. The damper is controlled by means of a "Johnson" thermostat. The coils are heated by means of hot water from the heating system, each section having an independent connection with the hot water heater; thermometers are provided for indicating the temperature of the water in the heaters.

The air washer has 450 nozzles placed 4 ft. from the eliminators which deflect the air five times and remove superfluous moisture. A tank under the air washer contains the water supply for the air washer. An automatic float valve keeps the water in the tank at a certain level and takes care of the loss of water which is absorbed by the air. The water is pumped from the tank and up to the air washer. A humidifier is connected to the water supply pipe and is arranged so that live steam at reduced pressure can be injected into the water going to the nozzles. A diaphragm on the water supply pipe controls the steam supply, the diaphragm being controlled by a thermostat in the air chamber. A Buffalo centrifugal pump driven by a 15 h.p. C. G. E. motor running at 1,250 r.p.m. circulates the water for the air washer.

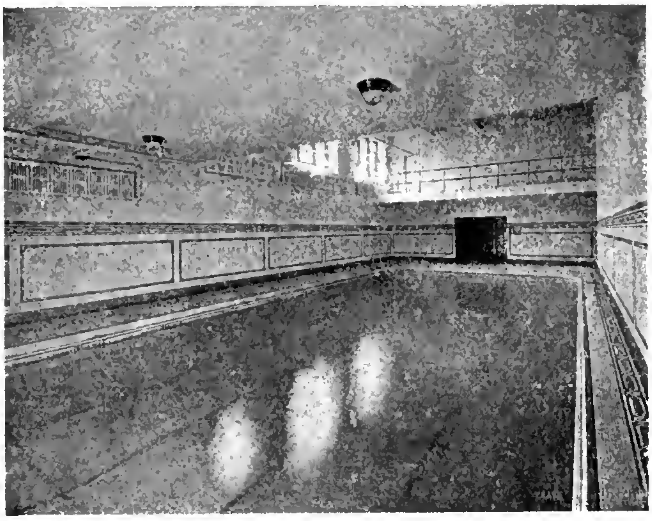
There are also installed two "Keith"

fans for exhausting the air from the toilets. One fan is located in a shaft alongside the stairway in the north side of the building and the other fan in a similar position on the south side. These fans were also supplied by Sheldons, Ltd., and are single width full housed type. Each fan has a capacity of 4,500 cubic feet per minute at 500 r.p.m., and is direct connected to a 2½ h.p. C.G.E. motor. Each motor is supplied with starting and stopping rheostats, cut-out switches, fuses and metal containing boxes. Two "Keith" type fans of Sheldons make, are installed for exhausting from the chemical laboratories. One of these is located in a pent house on the roof in a central position, while the second fan is located on top floor on the west side. Each of these fans has a capacity of 7,000 cubic feet per minute when running at 450 r.p.m., and is direct connected to a 5 h.p. C.G.E. motor. Each motor is equipped with a speed regulating controller and a cut-out starting in a metal containing box.

The draft for the forge shop is supplied by a fan in the fan rooms. This fan is full housed, and has a capacity of 2,000 cubic feet of air per minute at 400 r.p.m. This fan was supplied by the Canadian Sirocco Co., Windsor, Ont., and is driven by a 15 h.p. Canadian Westinghouse motor 230 volts d.c. The motor is controlled by a Cutler hammer rheostat. The entire heating and ventilating equipment was installed by the General Fire Extinguisher Co., Toronto. At the entrance of the large air intake in the subbasement is a rolling door for shutting off the supply of air when the system is not in use. The door is operated by a chain connected to a worm gear drive, the worm gear being driven by a 4 h.p. motor supplied by the Northwestern Mfg. Co., Milwaukee, Wis. The drive gear is located in the air intake near the rolling door.

Wiring and Lighting System

The lighting is d.c., 3-wire, 115-230 volt system, and the current is distributed through the building from six vertical ducts which have an inspection chamber on each floor. All wires are run in galvanized conduits approved by the Canadian Board of Underwriters. Four distributing panels are installed on each floor for the corridor and stairway lighting. The panels are made of black slate, and are equipped with the necessary switches, fuses, etc.



PLUNGE BATH AND SWIMMING POOL.

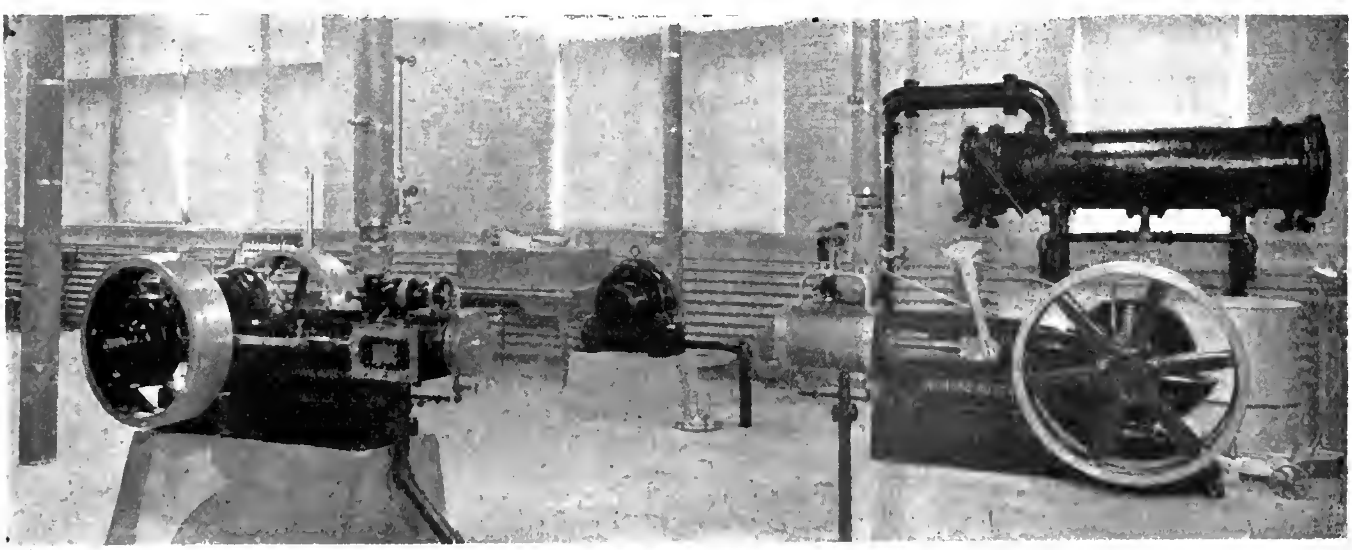
The lighting for the various rooms is distributed from the vertical ducts by means of steel encased panels on each floor. Each room is provided with a push switch, controlling the lighting there. The power for various departments is distributed in the same manner as the lighting current from power panels in the vertical ducts.

The feeders from the main switchboard are run in exposed conduit to the vertical ducts, the power and lighting feeders following the same course. Power feeders run to the machine and wood-working shops, there being a distributing switchboard in each.

The lamps in the various shops are 100 watt tungsten, with white enamelled shades. An exception to this is the machine shop, which has a number of indirect fixtures with single watt tungsten lamps. The power plant and laboratories are equipped with a direct light-system. The fixtures have special ribbed glass bowls each enclosing a 100-watt lamp. The corridor fixtures have translucent bowls each enclosing a 100-watt lamp, while red lights are installed at all the exits. The wiring was installed by Keiths, Ltd., Toronto. The fixtures in the power plant were supplied by the Tallman Brass Co., and the lamps by the Canadian Westinghouse Co., Hamilton, Ont.

Clocks, Telephones, Fire Alarm and Vacuum Cleaning Systems

The clock system was supplied by Howard & Co., Boston, Mass. There are 60 clocks installed throughout the building, all controlled from a master clock located in the assistant principal's office. The master clock has a 12-in. dial, and the movement is so constructed that it will completely wind itself from a 2-volt battery in 10 seconds or less. The secondary clocks in the boiler room, engine room, all the shops and laboratories



STEAM AND GAS ENGINE LABORATORY EQUIPPED WITH ENGINES, TURBINES, SURFACE CONDENSER, AND COMPLETE APPARATUS FOR TESTING POWER PLANT EQUIPMENT.

have 12-in. dials, and are enclosed in air-tight metal cases. All the other secondary clocks have 12-in. dials, and are enclosed in oak cases. A handsome 10-in. dial marble clock is installed in the front of the gallery in the auditorium. Current for the clock system is supplied from two storage batteries which are charged from the power circuit. The clock system was installed by Keith's, Ltd., Toronto.

An intercommunicating telephone system is installed throughout the building. There are at present over seventy stations, but these are being gradually increased as required. Nearly every room will have a telephone when the system is completed. The switchboard is located in the assistant principal's room, and a few lines are connected with the Bell Telephone Co. system. Current is obtained from a storage battery. The system was installed by Keith's, Ltd.. Toronto.

A very complete fire alarm and fire-fighting system is installed. Standpipes are installed throughout the building with a fire hose service at various points in each corridor. The standpipes are connected to the city water supply system. At various points in each corridor are glass break-boxes and bells, the latter of the vibrating type with 12-in. gongs. The bells are connected in multiple and are actuated simultaneously from any one of the fire alarm boxes. Annunciators are located in the assistant principal's room, and also in the engineer's office in the sub-basement. The battery for the system is located in the sub-basement, as is also a charging panel. The fire protection system was installed by the General Fire Extinguisher Co., Toronto, and the fire alarm system by Keith's, Ltd., Toronto.

A vacuum cleaning system is installed throughout the building. The installation is divided into two parts each being handled by a four-sweeper 6½ h.p. "Tuec" machine installed in the fan room, thus making an 8-sweeper plant in all. There are 220 valves in the building to which 50-ft. hose lengths can be attached, and the system is of such size that eight men can clean the building simultaneously without overloading the machines. The machines were supplied by the United Electric Co., Toronto.

Temperature Regulation Systems

The heating system is controlled by the "Johnson" system of temperature regulation. The temperature of each room is regulated by a thermostat which controls by means of compressed air a valve on the outlet of each radiator. The compressed air is furnished by a compressor in the engine room, and will be described later.

The ventilation is also controlled by the "Johnson" system. Roof dampers equipped with diaphragms are controlled from air operated valves located in the fan room. The roof dampers are located in the exhaust air ducts. The switches for operating these dampers are all arranged on a switch-board in the fan room, thus each damper is under the control of the engineers. The compressed air for the system is furnished by a duplex steam-driven pump located near the switch-board. There is also a motor-driven air pump used as an auxiliary. Air is pumped into tank at 30 lbs. pressure; this supplies a low-pressure tank and the system with air at 15 lbs. pressure. An automatic control is fitted and so arranged that if the steam pump fails the electric pump will take its place. The entire heat regulating system was supplied and installed by the Johnson Temperature Regulating Co., Toronto.

Swimming Tank

A well-equipped part of the plant is the swimming tank, and in connection with it, showers and dressing rooms. The plunge is 50 feet long by 25 feet wide, 6 feet deep in the centre and 5 feet and 4 feet respectively at the ends. It is lined with white glazed tile and is provided with continuous filtration. The filtration and heating plant is located in the pump room, the former having a capacity of 4,000 gallons per hour. The filter is of the pressure type and was supplied by the New York Continental Jewell Filtration Co., New York. The centrifugal pump was supplied by the Smart-Turner Co., and is driven by a 2 h.p. Canadian Westinghouse variable speed motor. Adjoining the filter is a water heater under thermostatic control. The latter is of the floating head type and is heated by live steam which passes through a reducing valve, or it can be by-passed.

The pump draws water from the lowest point in the swimming tank and delivers it to the heater. It is then filtered and returned to the tank. The system is so arranged that city water can be connected to the return pipe and then through the filter. The system is also arranged so that the engineer in engine room can tell the level of water in the tank. A "Johnson" thermostat control is installed in connection with this plant.

Steam and Gas Engine Laboratory

The equipment in this section is essentially for demonstrating the operating features of prime movers for the students. The equipment consists of two steam engines, a steam turbine and a condenser, while there is also apparatus for testing and research work. In course of time other equipment will be installed such as gas and gasoline engines, etc. There is ample space provided for further equipment.

Among the units installed is a horizontal high-speed centre-crank, 7-in. x 8-in. engine built by Leonard & Sons, London. Ont. This engine has a simple slide-valve, and the valve gear is so arranged that the valve may be adjusted to any desired travel, and any angular advance may be instantly applied to the eccentric. The engine is equipped with indicator connections to the cylinders and also to the steam pipe and steam chest. Experiments can be conducted with leaky pistons or valves and any other common derangement of a steam engine. The engine is equipped with a "Gardner" governor having a wide range of adjustment. Another unit is a "Leonard" engine of the same type and size as the one described above. This engine is equipped with an inertia shaft governor and ball valve. The governor is of course attached to the flywheel, which is bolted to a disc keyed to the crank-shaft in such a way that any governor position, also any weight of governor and spring tension, can be conveniently obtained.

There is also installed a 30 h.p. "Waite" steam turbine for experimental purposes supplied by Goldie & McCulloch, Galt, Ont. This turbine has a special Goldie & McCulloch dynamometer which has an exceptional range of application and special provision for water cooling. The experimental idea is fully carried out in this machine as well as in the other units as regards facilities for examining and adjusting all working parts.

Steam is supplied from the main boilers, the supply being so controlled with valves that any desired steam pressure can be obtained for any of the units. The exhaust steam is piped to a trench in the floor and may be discharged direct to the atmosphere or to a condenser. The condenser was made by the John Inglis Co., Toronto, and has 150 sq. ft. of cooling surface. It is provided with air pump connections. In connection with the condenser are two 60-gallon capacity measuring tanks, and two 1,200-pounds capacity portable "Fairbanks" scales. The tanks and scales are for measuring condensate to obtain amount of steam used.

The laboratory is equipped with pyrometers, calorimeters indicators, dynamometers, etc., and apparatus is being installed for testing lubricating oils, fuel, gases, etc. There will also be a collection of engine models, power plant apparatus and manufacturers' catalogues, the latter being for reference. The laboratory is also used as a lecture room and is furnished for this purpose. The piping was installed by the General Fire Extinguisher Co., Toronto.

Passenger Elevator

The passenger elevator is on the west side of the building, and serves from the basement to the top floor at a speed

of 250 ft. per minute, and with a capacity of 3,000 lbs. It runs in a fire-proof shaft, the machinery being located in the pent-house situated directly over the hatchway.

A car switch is provided with centreing device so that should the operator take his hand off the handle, the switch will immediately return to centre position and stop the car. The car is also equipped with wedge operated safety grips underneath the car platform.

Freight Elevator

The freight elevator serves from basement to top floor with a speed of 75 ft. per minute, and has a capacity of 4,000 lbs. The winding machine is of the direct connected type, and is placed in the pent house.

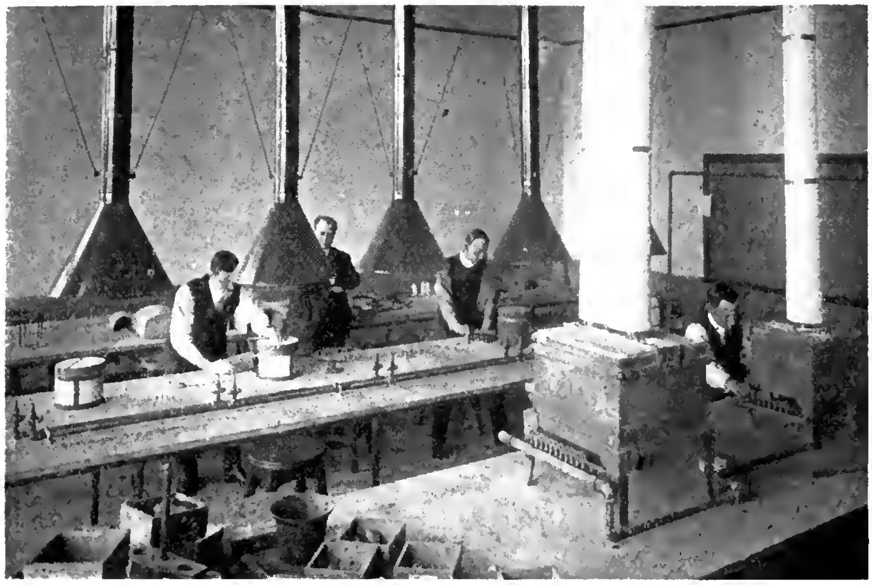
The gearing is constructed with steel worm and bronze worm wheel enclosed in heavy gear case, and running in oil to secure thorough lubrication. Other equipment consists of electric brake, automatic limit stops and automatic slack cable device. The motor is of 15 h.p. capacity, 230 volts, d.c., 4-pole, with commutating interpoles.

The operation is that of ordinary freight elevators, a hand cable passing up and down the side of hatchway. Steel guides are used for both car and counter-weight. The car is of hardwood construction, enclosed with neat hardwood sheeting on three sides with heavy wire screen on top.

Ash Hoist

The ash hoist is of the hydraulic plunger type, serving from boiler room to sidewalk. It has a capacity of 1,500 lbs., and a speed of 60 ft. per minute. The water pressure is 60 lbs. per square inch. This is used to lift ashes from the boiler room, and is provided with an iron door at the top which is opened and closed automatically by the car.

The lay-out of the power plant was prepared by the Canadian Domestic Engineering Co., Toronto, who also supervised the installation of the various units in both the power plant and gas and steam engine laboratory. The switchboard, while being designed by the Canadian Domestic Engineering Co., was supplied by the Northern Electric Co., and installed as has already been stated, by Keith's, Ltd.



METALLURGICAL LABORATORY WHERE ORES AND QUARTZ ARE ASSAYED AND PROPERTIES OF METALS STUDIED.

Art and Domestic Science

Instruction in cast, object and life drawing is provided, while the more useful forms of art such as clay modelling, pottery, stained glass work, metal work and wood carving form an important proportion of the school's activity.

The influence of knowledge on the details of everyday life is further demonstrated by the provision of suitable equipment for the education of future housekeepers in the various branches of Domestic Science.

Four kitchens, each 40 ft. x 30 ft. are furnished with individual stoves, utensils and tables for twenty-four students, while a separate supply room with refrigeration serves each kitchen. Laundry, sewing and dressmaking rooms, and a suite of rooms for housekeeping demonstration indicate the extreme thoroughness with which the question of technical education has been handled by the authorities, and if the students avail themselves to even a small extent of the opportunities for acquiring knowledge, the ultimate influence of such an institution on Canadian industrial life may well be far reaching, beneficial, and permanent, not only as a direct result of the teaching in the school itself, but through the general improvement in technical education throughout the Dominion which must undoubtedly take place as similar kindred institutions endeavor to emulate the worthy example and high standard set up by the Central Technical School, Toronto.

LABORATORY FOR QUALITATIVE CHEMISTRY. STUDENTS ARE HERE TAUGHT THE PRINCIPLES OF ANALYSIS.

For permission to prepare this article we are indebted to A. C. McKay, B.A., LL.D., Principal of the School, while Assistant Principals, W. S. Kirkland, M.A., and J. M. Warren, B.A., through their courtesy and direction contributed greatly to the pleasure of the work. Our thanks are due to the various directors of departments for special information and facilities afforded in the preparation of illustrations, etc.

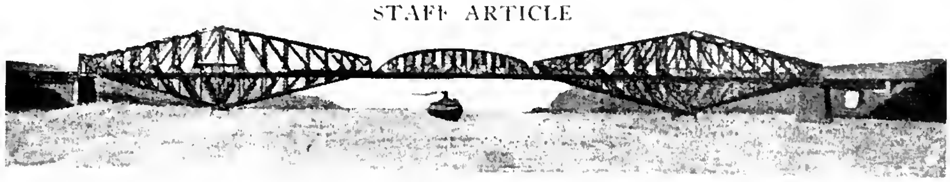
ERECTING THE NEW QUEBEC BRIDGE

STAFF ARTICLE



Public interest in the Quebec Bridge is again manifesting itself as the work of erection proceeds rapidly and successfully. The structure is now at approximately the same stage of completion as its ill-fated predecessor at the time of its collapse. The actual linking up of rails is scheduled for the fall of 1916, and the work from now on will occupy an increasingly important position in the ranks of Canada's many great national engineering feats.

DURING the past year, despite the unsettled conditions of the country, the progress of the erection of the new Quebec Bridge across the St. Lawrence River has been very satisfactory. At the close of last year the north shore anchor arm had been completed, with the exception of the upper portions of the three panels adjoining the main pier. The north portal and approach to the main structure was erected during the winter, also a certain amount of riveting.

The appearance of the structure at the commencement of operations in the spring of 1915 is shown in Fig. 1. About the middle of April the work was again started, and for the past eight months the pre-arranged programme of the contractors has been closely followed; in fact, certain sections were erected in shorter time than had been expected. The main posts, 10 feet square, which had been fabricated at the shops of the St. Lawrence Bridge Works, near Montreal, were transported by rail to the bridge site in twenty-seven separate sections, with the splice plates attached. The erection of these various sections necessitated very careful and accurate handling of the cranes and hoisting equipment. At the point where these various sections are spliced together, temporary platforms were constructed for the use of the men when riveting up the splices. This work is now practically completed. To enable the reader to have some conception of the massiveness of this structure, and the ingenuity demanded in the assembling of these many details, we would refer to Fig. 2. This shows the cap and top chord connection which forms the upper end of the main post. This piece alone weighs nearly 72 tons, and will be 310 feet above the main shoe, which rests on the concrete pier.

The work of assembling the structure proceeds on both sides simultaneously. The two north shore main posts, weighing approximately 1,000 tons each, were erected in thirty days. The main panels adjoining the centre posts were also assembled in about thirty days; the second panel on the north shore cantilever was completed in twenty-one days, with proportionately shorter periods on the successive panels.

Each section of the cantilever arm is completed as the work progresses, the rear boom of the traveller placing the bracing in position, while the side members of the forward panel are being erected by the front boom.

An interesting feature in the erection of the lower chords is the use of a steel platform called a "flying bridge." These chords have a vertical splice midway between panel supports, and it was necessary to construct this platform so as to take in one complete panel. The "flying bridge" is supported at the shore end by means of pins connected to the chords, and the outer end is held in position by means of links extending down from the upper web numbers. The platform is moved to a new position by the travelling crane.

Due to the fact that work is progressing from both sides of the river, it is essential that accurate calculations and observations be taken at stated periods of construction, to insure the perfect alignment of the structure. This is one of the chief points in connection with this huge engineering undertaking. When the north shore anchor arm was completed, the main post was

FIG. 1. NORTH ANCHOR ARM AS IT APPEARED ON NOVEMBER 30, 1914.

about fifteen inches out of plumb, due to the unbalanced weight of the uncompleted structure. At this stage of construction the lower chord had a camber or sag of several inches, while the members of the upper chord were so constructed that they were bolted in position temporarily while the cantilever arm was being constructed. As each panel of the cantilever arm was erected, its weight balanced that of the corresponding panel on the anchor arm, and the members of this panel were then permanently secured. As each succeeding section of the river arm was completed the corresponding shore arm section was secured in position. At the present stage, when the north shore structure is practically finished, the main post is still about five inches out of plumb. However, the calculations have proven so accurate that when the centre span is in position the centre post of each main truss will be practically perpendicular.

To test the accuracy of their calculations, the designers, at the completion of the cantilever arm, jacked up the shore or anchor arm to see what pressure was necessary to balance the structure, and their expectations were more than realized when they found they were within a few thousand pounds of the predetermined amount.

Another interesting feature is that of maintaining alignment of uprights and equalizing the strain during construction of the outer arms. In the triangle formed by the centre post and the main tension and compression members of the anchor arm main panel, a large horizontal brace, fitted with an adjusting screw, was used to overcome any undue stress in the various members caused by the continual changing in the shape of the panels as weight was added to the cantilever arm.

FIG. 5. NORTH SHORE TRUSS AS IT APPEARED ON NOVEMBER 7, 1915.

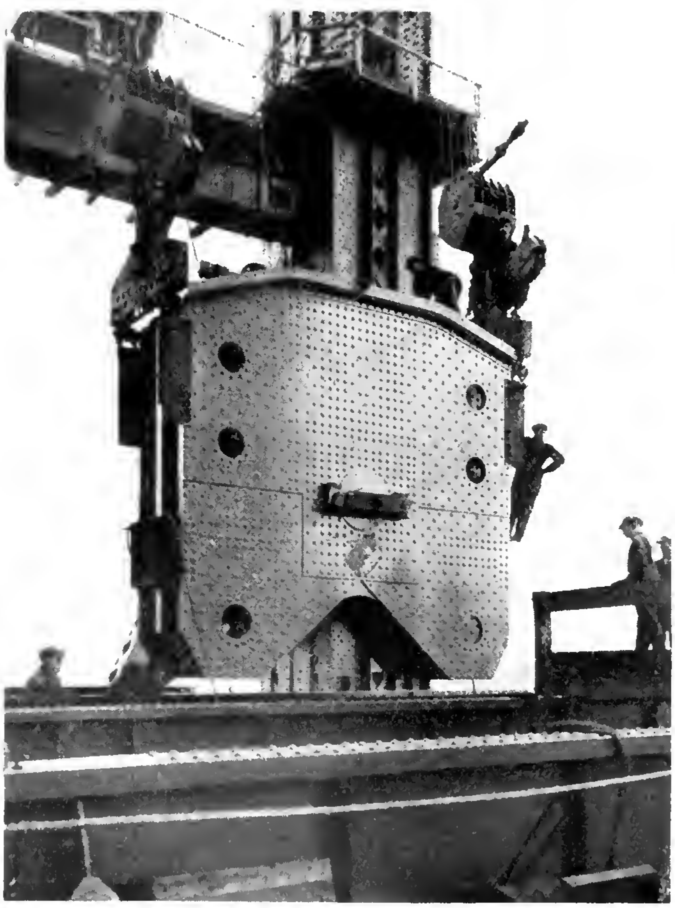


FIG. 2. MAIN POST CAP AND CHORD CONNECTION BEING HOISTED INTO PLACE.

The work on the south shore is progressing more rapidly than did that on the opposite side, as the experience gained in the erection of the north anchor arm and its falsework has greatly facilitated later construction.

On the south shore, the portal and anchor arm are finished as far as presently possible. Fig. 3 is a view of the south anchor arm as it appeared at the end of November, 1915. During the winter months little can be accomplished and work on the structure will be suspended until the arrival of milder weather next spring.

At the close of November, 1915, actual construction work on the north shore end was completed, with the exception of some riveting and other detail features. Since the middle of November workmen have been busy removing the falsework from beneath the anchor arm, and are also removing the traveler, which will be taken to the site where the centre span will be constructed.

The photograph reproduced in Fig. 4 shows an excellent view of the existing structure as it extends out over the waters of the St. Lawrence River, like the arm of some giant sentinel.

The view shown in Fig. 5 was taken from the south side of the river early in November, as the work on the north was just being completed.

At present about 150 men are employed at the works completing the fabricated material for next year's work. This part of the work is expected to be finished early in the spring. Some time in April operations will commence on the cantilever arm of the north shore truss; at the same time work will begin on the assembling of the centre span. This suspended portion, which will be 640 feet long and 88 feet wide, centre to centre of side trusses, will be 110 feet high at the centre, and will weigh approximately 6,000 tons. It will be erected at Sillery—about three miles below the bridge—on six specially-constructed pontoons, with falsework supported on concrete piers. Each pontoon will be 185 feet long, 32 feet wide and 12 feet deep, with steel frames and stiffening trusses, wooden sheeting and flooring.

It is anticipated that this section will

be ready when the south truss has been completed. The finished span will then be floated up the river and anchored in position beneath the bridge. The span will then be raised to its final position, a distance of 140 feet, by means of 2,000-ton jacks placed at each corner, and specially-designed hangers suspended from each of the cantilever arms. If the schedule of operations of next year's work can be carried out as successfully as the past year's programme, the feat of placing the suspended span in position will take place some time in October, and the bridge will be ready for the passage of trains in November, 1916. However, the regular traffic across the river will not take place until the spring of 1917. During the winter of '16 and '17 a great amount of detail work will be completed, such as the laying of walks, painting, etc.

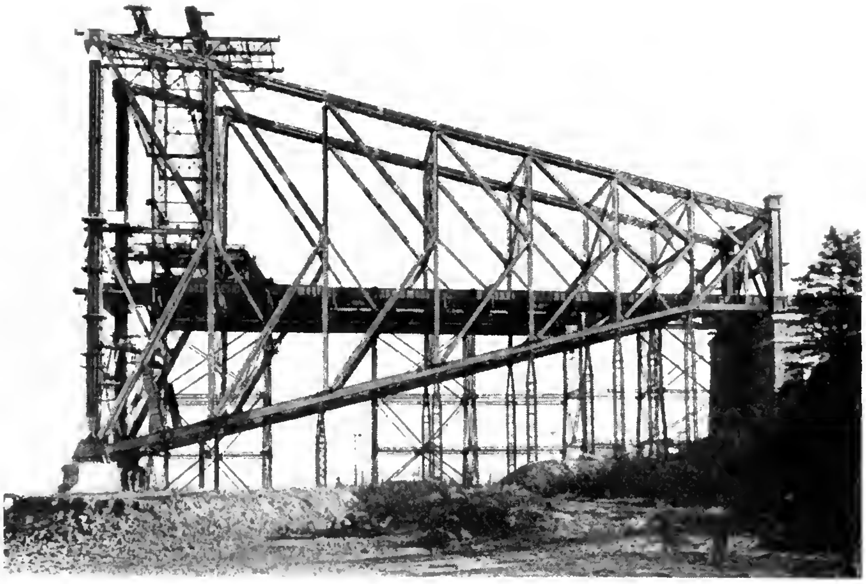

FIG. 3. SOUTH SHORE ANCHOR AS IT APPEARED ON NOVEMBER 11TH, 1915.

At the close of this season's work 45,000 tons of steel have been placed in position, and when the completed structure has been finally erected the total weight resting on the main piers will be about 65,000 tons, 55,000 tons being fabricated material.

Owing to the climatic conditions, and the wide range of temperature between midsummer and midwinter, which is from 100 to 120 degrees F, about 30 inches must be allowed for expansion and contraction in the total length of the bridge.

It is difficult to appreciate the magnitude of this undertaking from a brief description of the work being done. One requires to see the various component parts in course of construction and observe the manner in which the many problems of erection are being successfully overcome.

The designing, construction and erection of this bridge form one of the great engineering feats of modern times, and the official opening of this wonderful structure will mark the completion of the last link in the unbroken rail-to-rail highway, which will then extend from ocean to ocean.

A noteworthy feature of the work is the immunity from accident during erection. From the nature of the undertaking, a steady percentage of minor casualties is to be expected, but the number of fatalities has been surprisingly low. The efforts of the company to provide comfortable and attractive camp life for the men have met with all the success deserved, and such conditions have doubtless exerted a restraining influence on the workmen in exercising more than ordinary care in performing their duties.

CANADA'S IRON AND STEEL RESOURCES

Retrospective and Relative to the Munitions Demand

By HON. COL. THOMAS CANTLEY*

Steel prices covering every description of commodity into which the material enters have advanced to a prodigious extent, and we are certain that the limit has not nearly been reached. More than usual interest, as a result, is being taken in the question of Canada's resources, both as regards ore areas developed and available and plant equipment installed.

THE steel industry of Canada is represented by plants in three of the Eastern provinces—viz., Nova Scotia, Quebec and Ontario. Those of the first and last mentioned provinces are the most important, supplying over 99 per cent. of the total production. Probably the first effort in iron smelting in Canada was made in the Province of Quebec. During the early decades of the last century we find that various small enterprises were started in all three provinces—charcoal being used as fuel and local ores smelted. The amount of metal produced, however, was very small.

Nova Scotia

The Londonderry district in Nova Scotia was the first to assume commercial importance, and quite modern furnaces and plant were laid down about the middle of the last century. Iron was made here about the same date, and a rolling mill installed in 1860. It is of interest to note that the pig iron made at Londonderry had quite a good reputation, and was in demand. It is said that owing to its superior quality the British War Office, upon the recommendation of Sir William Fairburn and others, used it for the manufacture of ordnance in those days, and imported it into England for that purpose.

About 1875 there was further development in this district, with important additions to plant, coke pig iron being then made for the first time in Canada in a commercial way.

In a paper written on the iron and steel industry in 1885, Londonderry is referred to as the "site of the most important iron works in the Dominion." Up to 1887 it has produced over 200,000 tons of pig iron smelted from local ore—42,000 tons bar iron and forgings, and 40,000 tons of nail plate, wheels and castings. Operations at Londonderry have since been carried on intermittently—the last pig iron being made in 1908, and steel in 1912.

Further east in Nova Scotia, at New Glasgow, the first steel was made on a commercial basis in 1883, when two 20-ton acid-lined open-hearth furnaces were put in operation. Imported pig was used. Four years later the basic open-hearth process was adopted, thus making it possible to use local pig iron. Since this date all steel made in Nova Scotia has been exclusively basic open-hearth.

The first iron made in the Pictou district was by the General Mining Association, then operating collieries at Albion Mines in 1826, when they smelted local ores, using native flux with Beehive coke made from Pictou coal. Owing to the refractory nature of the ore used, the venture was not a success, and operations were discontinued. In Cape Breton the first pig iron and steel was made in 1899, and from this date on this has been the most important steel district in the province.

Quebec

From old records we learn of activity of the early French settlers in the Province of Quebec. How in 1737 the right of mining and smelting iron ore in the district of St. Maurice, near Three Rivers, was granted to a company by Louis XIV. From that date until a year or so ago mining and dredging of bog ore and smelting has been carried on around this district almost continuously on a small scale.

Attempts to smelt iron on a commercial scale were made at Moise in 1867, at St. Urban in 1873, at Hull in 1887 and 1872, but none with commercial success.

At Radnor and Drummondville, furnaces have been operated continuously from 1887 to 1912, using local ore, with locally-made charcoal as fuel. An average of about 8,000 tons per annum was made.

At the date of writing there are no blast furnaces in operation, and the only steel produced is in small open-hearth furnaces and electric furnaces, making castings, or the crucible method, making special steels, the tonnage involved being relatively small.

Ontario

An iron furnace was erected in Leeds County about 1800 and a second in Normandale a few years later. These initial efforts proved failures, but in 1832

*President and General Manager Nova Scotia Steel and Coal Co.

work was resumed by the other operators, and was carried on until 1847. The Marmora furnace, established in 1820, was unprofitably operated at intervals until 1875. A furnace was erected at Madoc ,and operated for eight or nine years; also at Houghton in 1854, and Burnt River, Haliburton County.

All these enterprises proved to be failures commercially, and we find in 1892 the Province of Ontario was without a single blast furnace. Two years later, in 1894, furnaces were put in operation at Hamilton by a company which now forms part of the Steel Company of Canada. These furnaces have been operated continuously since, and the growth for the following decade was rapid.

So much for history. The industry as it exists to-day may be conveniently considered as divided into two groups—one in Nova Scotia, the other in Ontario. This, both because the plants in both these districts form a natural unit, geographically and metallurgically.

Nova Scotia

In Nova Scotia the Nova Scotia Steel & Coal Co. and the Dominion Steel Corporation operate under almost identical conditions—they use ore and coal from the same beds and generally have the same metallurgical problems to overcome.

Ontario

The Ontario district may be subdivided into that of the Niagara Peninsula and the Lake Superior groups. All the important companies operate in the whole area, however, under very similar metallurgical conditions.

Niagara Peninsula

The important companies operating on the Niagara Peninsula are:

The Steel Company of Canada.

Canada Iron Corporation—Furnaces at Midland.

Canada Furnace Company—Furnaces at Port Colborne.

Standard Iron Company—Furnaces at Deseronto.

Lake Superior District

In the Lake Superior district:

The Algoma Steel Corporation—Furnaces at Sault Ste. Marie.

The Atikokan Iron Co.—Furnaces at Port Arthur.

We will now consider the different districts more in detail.

Nova Scotia

All its steel is made from Wabana, Newfoundland, ore smelted with retort oven coke, made locally from Cape Breton coal, local flux being used. The blast furnaces are seven in number, with a capacity of 1,930 tons per day. Open-hearth furnaces, including mixers, number eighteen, and also two 15-ton Bessemer converters.

Nova Scotia Output for 1913

Coke made, 713,000 tons, all from N. S. coal.

Iron ore imported, 940,000 tons, chiefly from Wabana.

Iron ore exported, 13,000 tons.

Pig iron made, 438,000 tons.

Limestone quarried, 514,000 tons.

Steel ingots made, 435,000 tons.

Nails made, 175,000 tons.

Steel billets made, 20,000 tons.

Rails made, 320,000 tons.

Merchant mill product, 19,000 tons.

The Atikokan Iron Company has a furnace in this district with a capacity of 100 tons per day, which has been idle since 1911.

The ores smelted in this district are partly native (Helen and Magpie Mines), but the greater part is imported from the American Lake Superior ore field. The fuel used is partly locally-made charcoal, but chiefly imported coke

HON. COL. THOMAS CANTLEY,
President and General Manager, Nova Scotia Steel & Coal Co., New Glasgow, N.S.

Steel billets for market, wire rods, merchant bar, wire and nail products, and forgings, 180,000 tons.

Lake Superior District

In the Lake Superior district there are four blast furnaces with a capacity of 1,050 tons per day, five steel furnaces, and two Bessemer converters. During 1913 this district produced the following material:

Algoma Steel Company

Pig iron made, 308,000 tons.

Coke made from American coal, 411,-000 tons.

Steel ingots made, 438,000 tons.

from Illinois or Pennsylvania. Recently 110 Koppers coke ovens have been built at the Sault for the purpose of coking imported coal at the furnace and saving the breakages inevitably obtained in transportation of coke. In 1913, some 600,000 tons of coal was imported for this purpose and 419,000 tons coke made.

Niagara Peninsula District

In this district there are seven blast furnaces with a daily capacity of 900 tons. The greater part of the ore and all of the fuel is imported for these furnaces, although a couple of the smaller companies use a certain tonnage of

local ores. Seven open-hearth furnaces provide the steel-making capacity of about 350,000 tons per year.

The Steel Company of Canada report having made 180,000 tons of pig iron, 157,000 tons of steel ingots, and 192,000 tons of finished merchant bar steel in 1913. The following statistics will be of interest:

Coke.—Coke made in Canada by the following companies:

On page 626 is given a table of particulars of steel furnaces and rolling mills.

Coke.—The Nova Scotia district is in the centre of Cape Breton coal field, and supplied itself with coke, and is thus self-supporting.

The Ontario district obtains all its fuel supply from the United States, either directly in the form of coal or as coke. The coke imported and used in furnaces in 1913 amounted to 706,888 tons.

Iron Ore.—The iron ore production of Canada in 1913 was 307,000 tons. Since then the production in the Province of Nova Scotia and New Brunswick has ceased. Production in Ontario in 1913 was 195,000 tons; in 1914, 244,000 tons. Of the latter amount, 184,000 tons was shipped to Canadian furnaces and 60,000 exported to the United States. Of the 195,000 tons mined in 1913 in Ontario, Helen and Magpie Mines shipped 22,000 tons, Moose Mountain 3,300 tons, Belmont Mines, Hastings Co., shipping to Port Colborne furnaces.

Imports of ore in 1913 from Wabana (Newfoundland) into Cape Breton were 940,000 long tons. Imported into Ontario from the United States 1,072,156 tons.

Flux.—The total limestone used amounted to 630,000 tons, of which 346,000 tons were imported. Previous to 1896, pig iron was made entirely from Canadian ores. Since that date, however, increased quantities of imported ore have been used, as well as imported fuel and flux, and in 1914 about 94 per cent. of the ore used, 50 per cent. of the coke and 56 per cent. of the limestone was imported.

Blast Furnaces

There are 22 blast furnaces in 12 separate plants owned by mine companies, with a total theoretical capacity of 1,500,000 tons. In 1913 five of these furnaces were idle. It is improbable that a greater tonnage than 1,350,000 tons can be obtained in 1915. The following table shows the production of pig iron by grades for 1913—Basic, 558,524; Bessemer, 227,662; Foundry, 225,231; all other, 3,701. Total, 1,015,118.

Blast Furnace Plants

1915. Company.	Address	Location of Plant	Blast Furnaces and Tonnage

Steel.—There are four plants with installation of 30 furnaces and four Bessemer converters, having a total capacity of 1,250,000 tons a year. It is improbable that this amount can be exceeded during the coming year by more than 100,000 tons, and it should be borne in mind that 300,000 tons of this capacity is Bessemer steel which is not accepted in the manufacture of munitions. In addition, there are eight or nine steel casting plants, operating either small open-hearth furnaces or converters. The tonnage derived from this source in 1913 was 39,217 tons, when the total production of steel amounted to 1,168,993 tons made by nine companies.

Nickel Copper Smelters

Electric Smelting.—In the above estimates we have not made any allowance for such additional tonnage as might be obtained by electric smelting. The tonnage of steel derived from this source in 1913 was under 5,000 tons, not including the tonnage obtained on ferro-alloys, which amounted to 8,000 tons off. The problem of electric-made steel is a large one. Melting scrap in a relatively inexpensive steel furnace where electric power is cheap is very attractive. This no one doubts. The difficulties that may be encountered in securing any great tonnage in this way, while problematical, are bound to be enormous, and it is unlikely that our figures will have to be changed materially because of the tonnage derived in this way.

Rolling Mills.—The blooming mill capacity of this country will probably handicap the production of war munitions as much as the shortage in steel ingot capacity.

The table on page 626 shows the production of finished rolled products:

In glancing over the statistics of the industry in view of the present crisis in the affairs of Canada and the Empire, for our present purpose it will be noticed that the industry was of a comparatively slow growth. Very little was done before 1880. There was no cogging mill in the country till 1883.

*Idle during 1914.

The first great impetus was given by the iron and steel tariff of 1887, brought down by Sir Charles Tupper, that far-

seeing and progressive Canadian, the indomitable fighter, and the Dominion's greatest constructive statesman, who, in the fullness of his days, has so recently rejoined his chief and the other fathers of Confederation. To him full credit should be given for having the faith and the necessary vision to create conditions which led to the foundation being laid upon which our present achievements rest.

With the subsequent changes in import duties there was little further development until the second stage of development commenced at the close of the last century, brought about by the action of the Government in putting in force a graduated system of bounties.

This resulted in large iron and steel enterprises being undertaken both in Nova Scotia and in Ontario, to which we have already referred, with the result that in the latest normal year for which we have complete statistics the production of pig iron was 1,128,967 tons and steel 1,168,993 tons.

It is a melancholy reflection that even in such a banner year as 1913 the iron and steel production of Canada was little more than half the total requirements for the same period.

During 1914, owing to the world-wide depression, which was perhaps even more keenly felt by the iron trade of Canada than of any other country, the output fell off considerably.

Shortly after the outbreak of war, when the British War Office began to look about them for supplies of large types of ammunition, they turned first to the United States, when, thanks to the initiative, energy and courage of the Minister of Militia, General Sir Sam Hughes, Canada was invited to aid in the supply of munitions.

That we were able to do so was due entirely to the fact that in the previous years manufacturers in the older provinces by the sea, where the pioneering work in the iron and steel trade of Canada had been done, were in a position to supply the steel and make the forgings; other manufacturers were able to supply the various component parts. These establishments and other engineering shops the Shell Committee co-ordinated, and thus supplied to the War Office the first order entrusted to them of 200,000 shrapnel shells.

The development of the steel trade of Canada, which made the supplying of these shells possible, later resulted in placing in Canada, between October, 1914, and June 10th of the present year, munition orders alone to the amount of more than $160,000,000 and has provided employment for thousands of workmen, not only in the iron and steel industry, but workers in other metals, and a large army of mechanics, who, so far as can be seen, would otherwise have been without employment.

During the nine months of the present year there has been shipped to Great Britain from Canadian ports more than 4,229,000 shells—about 25 per cent. of which were fixed ammunition. Here perhaps it may be of interest to state that Scotia, who first of the Canadian steel companies undertook to supply shell steel and shrapnel shell forgings, made at their New Glasgow plant in the twelve months ended October 31st last, a total of 2,145,525 shell forgings, more than 20 per cent. of which were of the largest size high explosive shells yet made in Canada.

This munitions work has provided employment for a very large number of workpeople in various walks in life, outside of the iron, steel and closely allied industries. For instance, over 1,000,000 ammunition boxes have been supplied, calling for more than 10,000,000 feet of lumber, while wooden cases for other munition exports have in addition called for more than 25,000,000 feet.

The grain crop of Canada—the largest she has ever harvested—is now slowly filtering into transportation channels for shipment to Britain. Other agricultural products are also being turned into cash, but during the past spring and summer, while the crops were growing, Canadian exports increased in volume at a rate never before experienced in the history of the country, and largely as a result of the embarkation of this country in the supplying of munitions, due primarily and possibly only, because Canada had built up a steel industry, relatively small, it is true, but sufficient for the moment, and this because some Canadian statesmen and the pioneers of the industry had builded better than they knew. The Dominion will during the next fifteen months probably export to Great Britain munitions aggregating in value not less than two hundred and possibly three hundred millions of dollars, fully eighty per cent. of which will be wholly the product of Canadian labor—coal miners, iron and steel workers, machinists, and others working in the engineering shops of the Dominion.

We have spoken of the volume of this munition work as being between $200,000 and $300,000,000. This is a wide variation. The uncertainty in regard to the amount resolves itself into a question of Canada being able to obtain either from her domestic furnaces or elsewhere sufficient steel for shell forging, for there is no doubt that the engineering shops of Canada can overtake the assembling and finishing of shells of the value of more than $300,000,000 if the steel can be secured.

Steel Ingot Production

The year 1913 marked the greatest production of steel ingots by Canada in that country's history, when the total output of all the furnaces in the Dominion was 1,048,538 tons, while during the year 1914 the output dropped to 775,000.

Little has been added to the steel production capacity of the Dominion since the close of 1913, and it is doubtful if Canada during 1915 will even by straining all its resources produce 1,100,000 tons.

Assuming new equipment is added, as it probably will be, to a moderate extent, we may, therefore, look for under the most favorable conditions a total output of not more than, say, 1,250,000 tons of steel ingots.

Turning now to the United States, an extraordinary situation at present prevails. Never in the history of that country has the demand been so great. Difficulty in securing steel of every description has developed rapidly during the past few weeks, and there are at present many signs of excitement in the iron and steel trade.

During the month of October last the United States production of pig iron for the first time on record exceeded 3,000,000 tons (i.e., 3,125,491), exceeding that of September of this year by more than 95,000 tons, and being almost double that of the corresponding month of 1914, when the daily output was 51,000 tons.

The amazing consideration is that, while the United States to-day is producing pig iron at the unprecedented rate of 37,500,000 tons a year, prices are advancing daily. The advance in prices in the first week of November was 50 cents a ton on coke iron and $1 a ton on charcoal iron, while basic iron has during the year advanced from $12.50 to $15.80 a ton.

Demand For And Price of Steel

So far as steel is concerned, the demand and increase in price is even greater than in the case of pig iron. Indeed, the situation is unique as regards price of finished steel, and at present it is difficult to find a seller who can make deliveries.

Eastern and Western mills are alike congested with business, and in but a few cases it is possible to find mills having any open capacity.

Plate mills are filled up with car, locomotive and shipbuilding tonnage. The railways, which were almost entirely absent from the market for many months past, have recently given out orders for a large quantity of rails, while about 300,000 tons, it is understood, have been booked for export within the coming two months to Russia.

During October the American railways also bought more than 27,000 cars, and probably more than 10,000 have been booked for export to the Russian Government.

As regards steel plates, the increase in price and difficulty is even greater, and the suggestive fact is that, notwithstanding these great advances in price, it has failed to shut off demand in the least, and in most lines it is not now a question of price, but where to find a mill that will undertake to guarantee deliveries. While the situation as regards structural steel is grave, it is in forging billets that the situation is most acute.

Steel bars in November, 1914, sold in Pittsburg at $1.10, while in November of the present year the price was $1.50, or a 36 per cent. advance; while in forging billets the difference was much greater, the figures being $25 and $42 respectively, or an advance of 68 per cent. Indeed, high carbon steel sold in large quantities at previously unheard-of prices, even during the closing days of October, orders aggregating more than 60,000 tons of high carbon forging. Billets were reported as placed at prices as high as $56 per ton, Pittsburg. Further, it is stated that the British and Allied requirements for high carbon shell steel alone—which are now becoming insistent —will total up the enormous figures of 20,000,000 tons.

It is, therefore, clearly evident that Canada and the United States will, during the coming year, face a steel famine unprecedented in the history of this continent.

The outcome will be as interesting as it will be far-reaching, and it will probably interfere more or less effectively with some of the profits so easily shown on paper as capable of being earned by munition plants yet unbuilt and dependent upon actual iron and steel producers for their raw material.

It should also provide a moral to the country at large to build up what is one of the most fundamental national assets—a strong, well-rounded and self-dependent iron and steel industry.

This article was prepared in the first instance for presentation before the Montreal Metallurgical Society, and the name of its author is sufficient guarantee not only of accuracy of detail, but of painstaking thoroughness in tracing the Canadian iron and steel industry from its inception up to date.

INDUSTRIAL ACTIVITY BECOMING GENERAL

THE Canadian Bank of Commerce has begun the publication of a monthly commercial letter, through which customers and correspondents of the bank will be regularly apprised of the condition of foreign and Canadian trade. The initial report, dated this month, treats of recent agricultural and manufacturing progress in an interesting and authoritative fashion. On the situation of trade generally the report speaks in this encouraging way:

"Industrial activity is becoming more general throughout the Dominion. Lumber mills are encouraged by the lower stocks at distributing yards on the prairies and by the increasing demands from the Eastern States.

"Paper makers and pulp mills are, generally speaking, quite active as a result of better demands from the United States. Prices are slightly higher on new contracts, and the outlook is regarded by the trade as being exceptionally bright.

"Textile plants are not only employed to a very large extent in filling orders for military purposes, but they have on their books orders for domestic requirements in quantities which denote more normal demands. Their chief trouble for the time being is in procuring raw materials and dyes.

"A scarcity of steel suitable for certain classes of ammunition and the very high level of prices for all metals are causes of some apprehension in certain lines of industry."

High Explosive Shell Manufacture

STAFF ARTICLE

As in the manufacture of 18-pdr. shrapnel and 3.3 high explosive shells, a widely diversified industrial enterprise found opportunity to exhibit inventive genius and apply it to secure high quality and quantity output, in like manner we find in the production of the larger size high explosive shells that equally satisfactory achievements is being attained.

BUILDING CONTRACTORS MAKE 4.5-IN. SHELLS

PREVIOUS to the outbreak of the war the plant here described was wholly employed on large building contracts. Realizing, however, the necessity and advisability of co-operating with the Shell Committee in the manufacture of munitions, it was decided to rearrange their carpentry shop and install the necessary equipment for the machining of 4.5 high explosive shells.

At first the shell forgings were received from outside sources, but latterly a forging department was added (a section of the large stone shop being utilized for this purpose), and now the shells are being made complete from the billet. The various operations and their purpose constitute the substance of the data that follows:

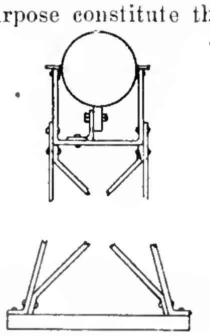

FIG. 2. SECTION OF BILLET CONVEYOR.

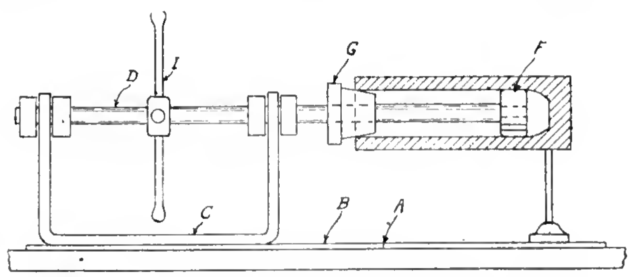

FIG. 3. GAUGE FOR SHELL WALL THICKNESS.

Receiving the Billets

The billets from which the forgings are made are received in carload lots from the steel foundry where the steel is made and cast into ingots preparatory to being cut into billets of the required dimensions.

Each billet has stamped on it the number of the heat or melt from which it was made, also the carbon content is plainly marked. The billets are carefully sorted, according to heat numbers, so that test pieces from two shells of each heat may be selected for test, according to specifications. As a carload may contain quite a few heat numbers, the work of separating and arranging the billets frequently assumes considerable dimensions, as any carelessness or neglect leads to complications at a later stage, which give considerable trouble.

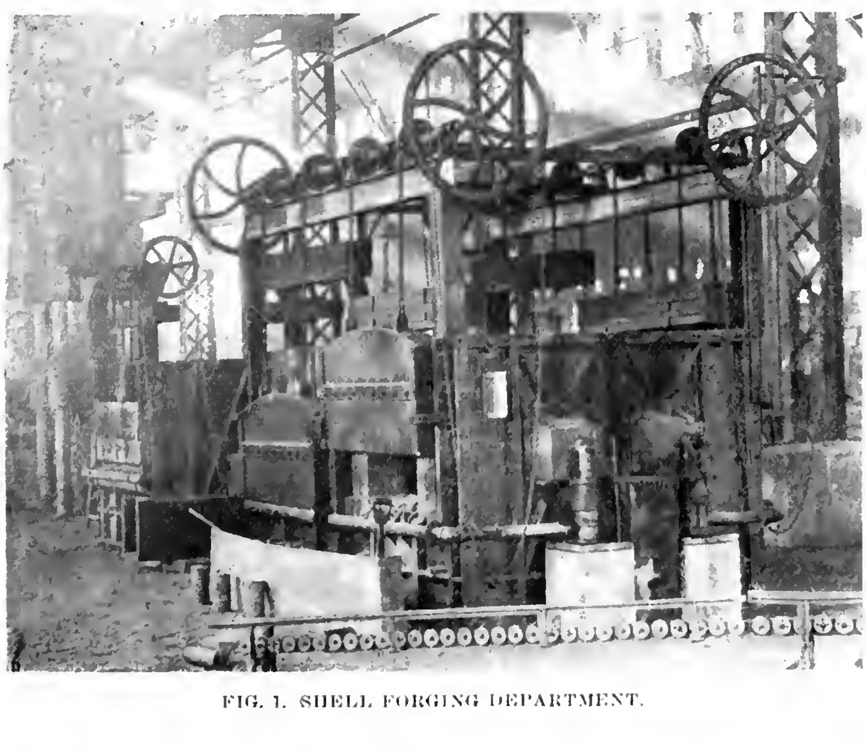

FIG. 1. SHELL FORGING DEPARTMENT.

To facilitate the handling of these billets from the car to the shop floor, the carrier shown in the foreground of Fig. 1 is used; this can be placed to transfer the blanks to any desired position. These carriers were supplied by the Canadian Matthews Gravity Carrier

Co., of Toronto; a section of this device is shown in Fig. 2.

Forging Department

When the billets have been examined and placed in piles, they are ready to be heated for forging. The forge department shown in Fig. 1 contains two double and two single oil burning furnaces, made by the Mechanical Engineering Co., and one 350-ton and one 200-ton hydraulic presses installed by the Southwark Foundry and Machine Co., of Philadelphia. These presses are operated by two hydraulic pumps, in conjunction with an accumulator. One of these, a direct-driven pump, was supplied by Dean Bros., of Indianapolis, and the other, a belt-driven pump, was installed by the Deane Steam Pump Co., of Holyoke.

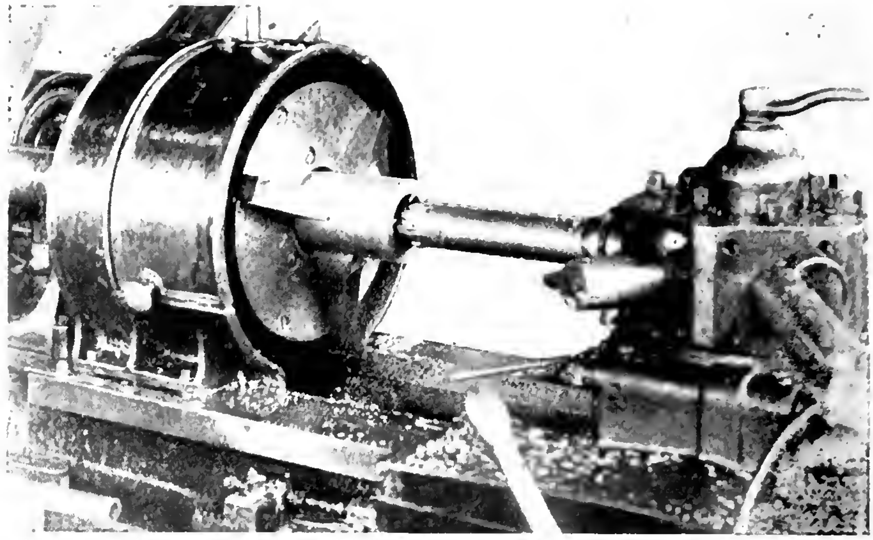

FIG. 5. CLOSE VIEW OF INSIDE BORE MACHINING OPERATION.

Heating the Blanks

Each furnace chamber contains a charge of about 60 billets, which requires a couple of hours to heat. When the blanks have been heated to about 2,200° F., they are ready for forging. The door of the furnace is then opened and an operator removes one of the hot billets with suitable tongs, which are suspended by a chain from a small trolley car which travels on an overhead rail from the front of the furnaces to the presses.

Drawing the Shell

The billet is placed on a metal-covered table, where two men with scrapers remove the scale. This scale must be thoroughly removed to insure clean shells and prevent wear to the punch and die. When the blank is quite free from scale, it is placed in the die (which has previously been swabbed with graphite and oil), a small quantity of coal dust thrown on the top, and the ram forced downward, which causes the punch to enter the billet, and as the punch proceeds downwards, the metal flows (in a solid state) upwards around the punch. When the punch has completed its work, the ram is raised to its upper position. As the ram goes up, a cross bar below the die, connected to the ram by two chains, comes in contact with the knock-out, which forces the finished shell from the die. The shell is then removed and placed in piles, care being still taken that billets of different heat numbers do not become mixed.

Allowing for all ordinary changes and repairs, an average output is maintained of 40 an hour on the large press and 35 an hour on the smaller press during the twenty-four hours.

While the charge of billets from one furnace is being forged the blanks in the other furnace are being heated.

When the plans of installation were being considered it was decided to place the furnaces in the position shown, as this arrangement prevents the heat of the fires from striking the press operators when the furnace doors are opened.

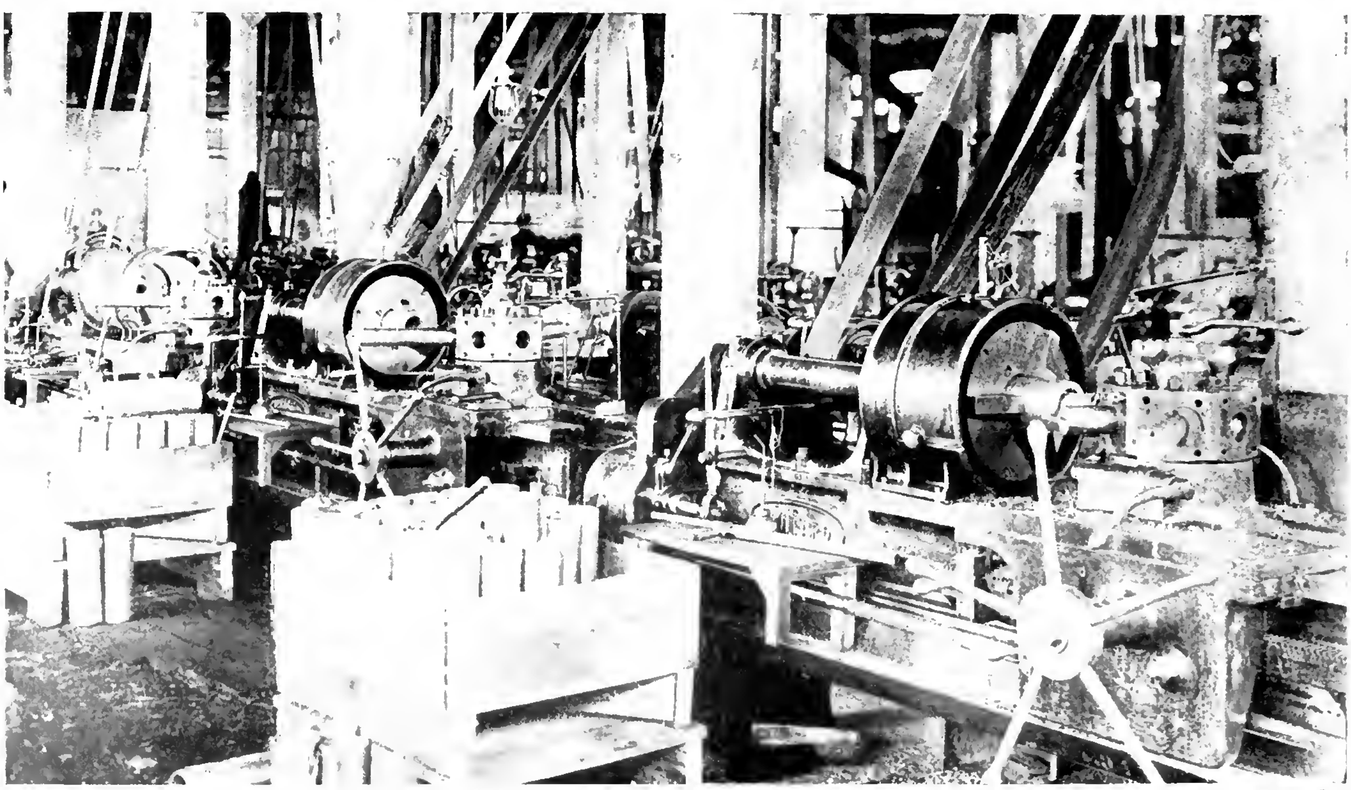

FIG. 4. GROUP OF "SINGLE PURPOSE" LATHES MACHINING INSIDE OF SHELLS.

Rough Shell Inspection

After the shells have cooled, they are inspected for defects and gauged for length and concentricity of internal and external diameters.

The gauging device in use is shown in Fig. 3. The U-shaped piece C is secured

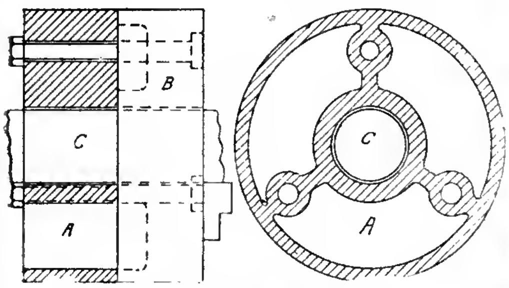

FIG. 6. CHUCK EXTENSION PIECE FOR INSIDE BORE MACHINING.

to the plate B on the bench. On the shaft D is a three-point fixed collar F and a movable collar G, tapered to enter the mouth of the shell. When the shell has been placed on the shaft it is revolved by means of the handle I, and the length of the gauge is such that useless shells are very readily detected.

Cutting Off and Centering

The first machining operation is cutting off the open end and facing the base to the required length. This is accomplished on three Hall cutting-off machines, the output of each machine being between 110-115 in ten hours.

To centre the base, the shell is placed on a mandrel held in the spindle of a small lathe and the centering drill forced in from the tailstock spindle. Owing to eccentricity of the wall thickness it is sometimes found that this centre would not allow the outside diameter to finish to the desired dimensions. When this trouble arises the centre is drawn over and a special boring operation is performed to rough out the inside.

Rough turning the outside diameter is done in four Lodge & Shipley 22-in. engine lathes, the open end being forced on a short tapered arbor, with inserted cast steel hardened pieces, serrated on the edges to drive the shell, while the base is supported by the tailstock centre. One roughing cut is taken over the entire length, and each machine has an output of about 110 shells in ten hours, lubricant used on machining operations being Economic water oil and Justrite cutting compound. This removal of stock from the rough shell allows the forging strains to readjust themselves and re-

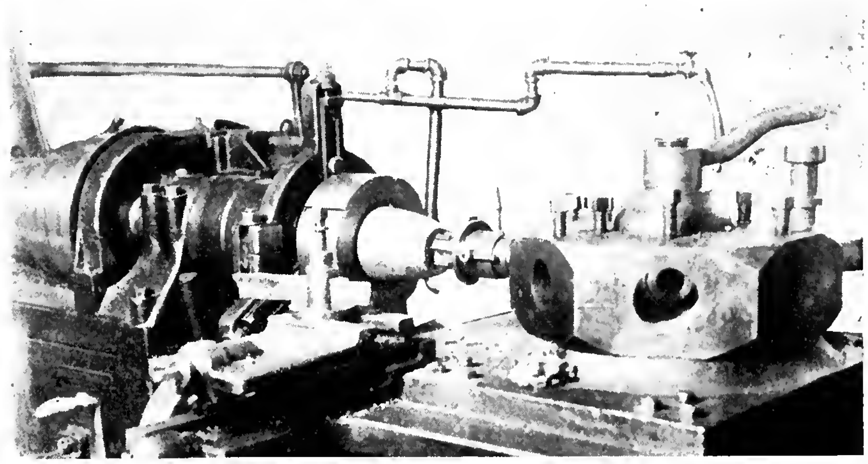

FIG. 8. BORING, RECESSING, FACING AND THREADING SHELL NOSE.

duce the possibility of subsequent warping.

Machining Inside Bore

The machining on the inside bore is accomplished on seven Bullard single

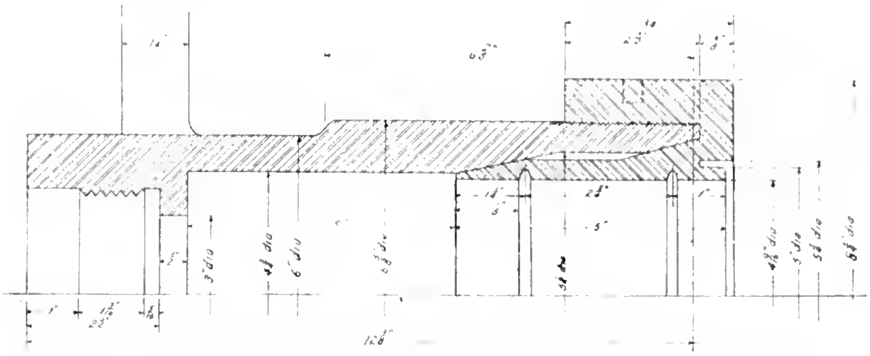

FIG. 9. POT CHUCK USED WHEN BORING, RECESSING, FACING AND THREADING SHELL NOSES.

purpose projectile lathes, a group of which are shown in Fig. 4. These machines are driven by 6-inch Balata belting. A closer view of the operation is seen in Fig. 5. To avoid the use of a steady head and retain rigidity during the machining of the bore, an extension piece was placed at the back of the chuck and secured to the face plate.

A sketch of this is shown in Fig. 6. The piece A, which is cored out to eliminate weight, is bolted to the chuck as shown, and also to the face plate on the lathe; it is then bored out a free fit for the rough turned shell.

The cycle of operations is shown in Fig. 7; roughing ing the bore and roughing out mouth of shell; roughing out base contour and finishing open end; finishing bore and base contour. An average production of 70 to 75 shells a day of ten hours is maintained on each machine.

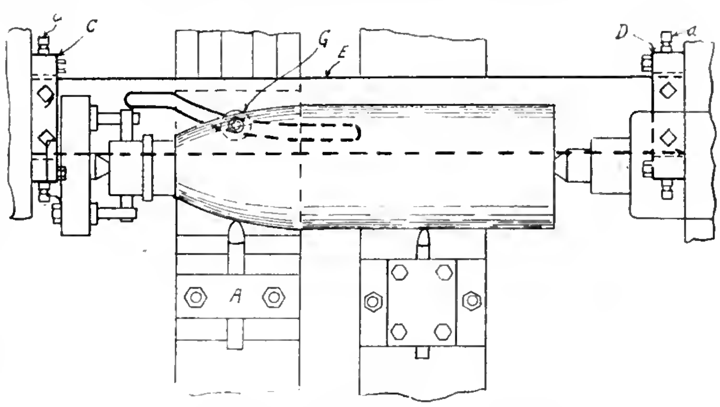

FIG. 11. PROFILE FORMING ATTACHMENT.

Forming the Nose

When the shells have been finished on the inside, they are taken to the nosing department, where the open ends are placed in holes in the face of a furnace and heated to a temperature of about 1,600° F. There are two of these furnaces, one constructed by the Peter Lyall & Sons Construction Co., and one installed by the Strong, Carlisle & Hammond Co. In the heating of the shells for nosing, much depends upon the skill and experience of the man in charge of the fire, as the shell must be heated to a certain distance from the open end to obtain the best results; a careless or inexperienced heater may be the cause of an undue quantity of rejected shells. Heating too far down the shell will allow the metal at the lower end of the profile to yield under the pressure, and the opening at the nose may not be small enough. On the other hand, when the amount heated is short of that required, the pressure upon the die when shaping the shell may become so great as to result in a cracked or damaged die.

When the shell blanks have been heated in the required manner, they are placed in a hydraulic press and the mouth of the shell formed to the shape desired. The forming die is made of cast steel, hardened, and enclosed by a water jacket, which prevents the die from being over-heated. The two presses working on this operation were supplied by W. R. Perrin, of Toronto, who also supplied the pump and accumulator. The daily output of this department is over 600 shells in ten hours.

Threading Inside Nose

Four lathes are operating on boring, threading and finishing the nose; two C. M. C. 20-inch engine lathes and two Edwin Harrington, Son & Co. 18-inch gap lathes. All these lathes are fitted with special turrets, designed and constructed in the shop. They are very rigid, showing no vibration during operations. On the two last-mentioned lathes these turrets can be placed on the saddle without interfering with the present cross slide tool support.

The sequence of machining on this operation is boring, recessing, facing and threading; the latter being done with Murchey collapsible taps. The chuck used on this operation is shown in Fig. 9 and is self-explanatory. Output on each machine is about 150 shells in ten hours.

Inside Nose Contour

Contrary to the general method of forming the inside nose contour during the above operation, this is done on an old Jones & Lamson turret machine, where the inside profile is formed at the rate of 30 an hour. This operation is to clean up and remove any inequalities (caused by the formation of the nose in the hydraulic press) and to insure perfect concentricity with the rest of the bore. This is necessary to insure the shell being in perfect balance.

Finish Turn and Profile

A special driving plug is now screwed into the threaded nose and the shell placed between centres to have the outside diameter and nose profile finished.

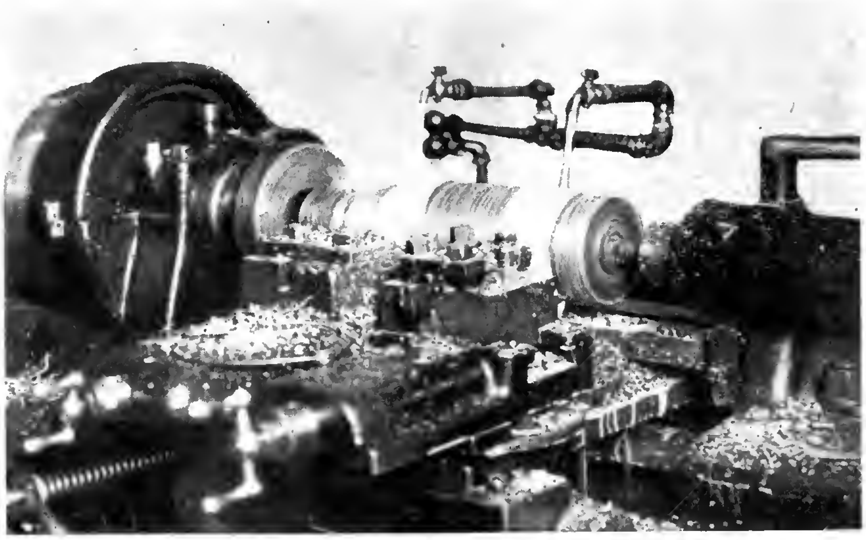

FIG. 10. "WALCOTT" LATHE, FINISH TURNING AND PROFILING SHELL BODIES.

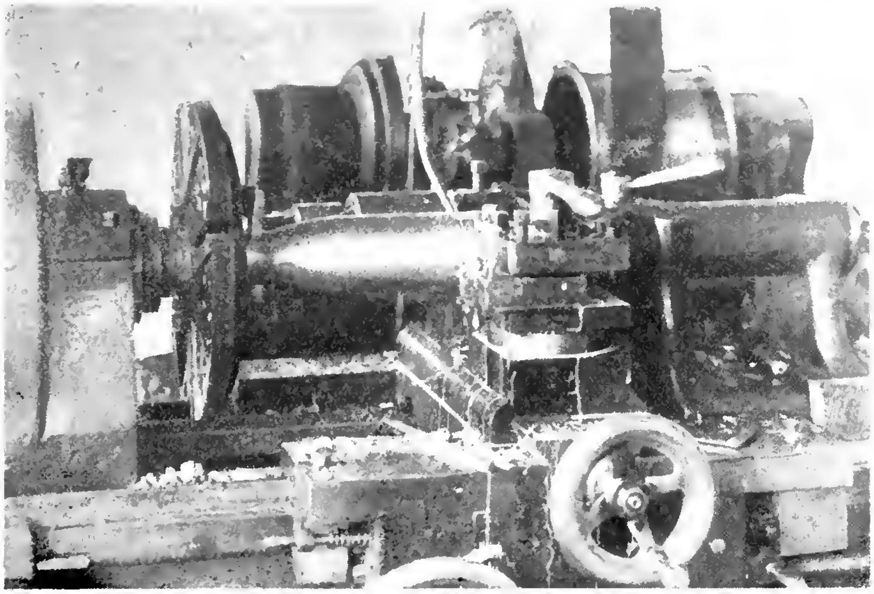

FIG. 12. GROOVING AND WAVING FOR COPPER BAND.

Four 20-in. engine lathes are used for this operation—two Greaves Klusman and two Walcott; a view of the latter in operation is shown in Fig. 10, with two tools working, one on the parallel portion and the other on the contour. This method of using two tools increased the output from 85 to 125 shells in ten hours.

Fig. 11 shows a sketch of the profile forming device (in heavy lines) as applied on these lathes. The movement of the cutting tool A is controlled by the roller G in the cam slot, cut in the bar E, which is secured to the brackets C and D, fastened to the headstock and tailstock respectively; adjustment of the cam plate is easily and quickly obtained by means of the set screws (a).

At this stage the shells are examined and weighed and usually found to be slightly overweight. This excess stock is faced off the base; the approximate amount to be removed being about 1-64 of an inch per ounce excess.

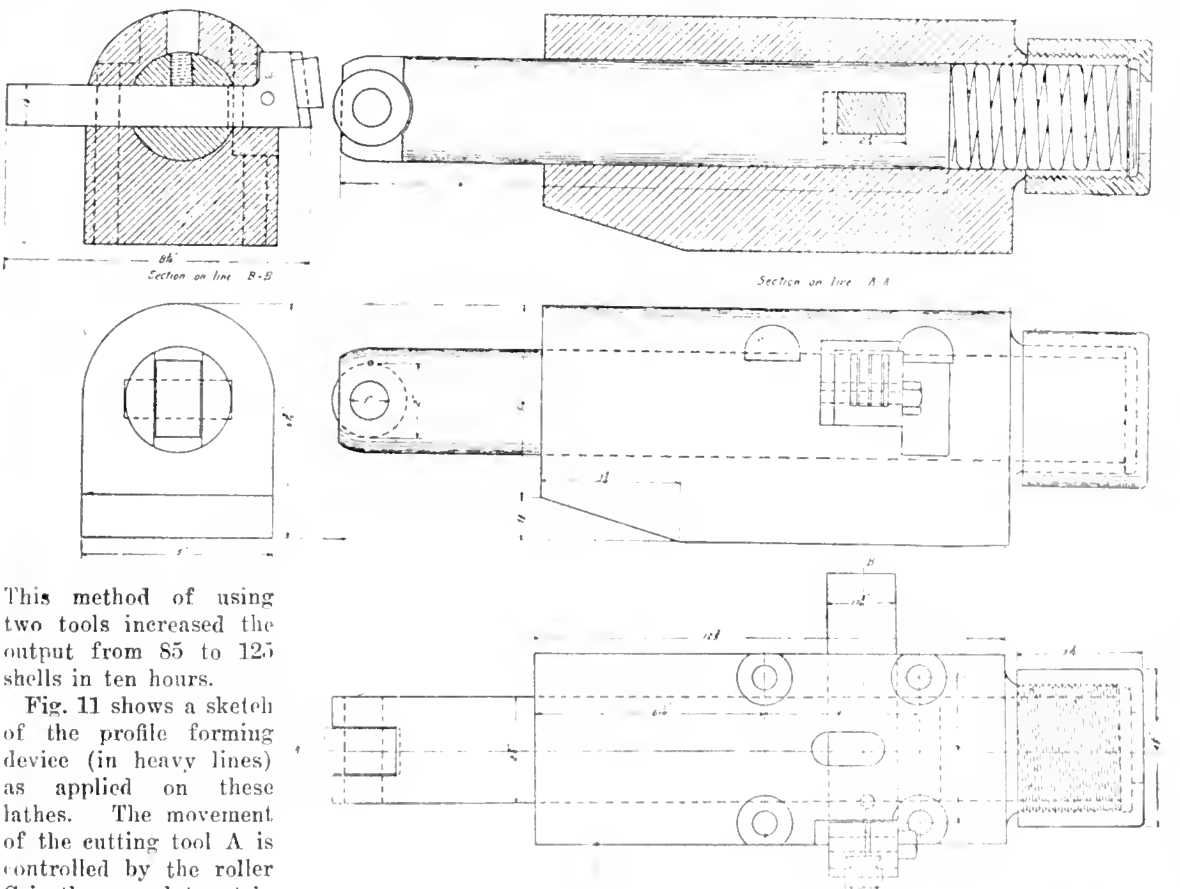

FIG. 13. DIAGRAMMATIC REPRESENTATION OF WAVING DEVICE.

Groove and Wave

The grooving and waving to receive the copper band is performed on two 20-inch engine lathes, manufactured by the Norwood Engineering Co., of Florence, Mass. These lathes are fitted with special waving attachment, designed by the shell shop superintendent and constructed in the shop. The output on this operation is 125 shells in ten hours from each machine. The construction of the waving device can be more clearly understood by referring to Fig. 13.

These waving ribs are then notched in three places with a cold chisel to allow the escape of air when the copper band is being pressed on. The ribs are triangular-shaped, so that in the closing of the copper band, under compression, the pointed ribs will cut their way into the copper freely. Close adherence to specifications, both in forming the groove and pressing on of the band is essential, as very careful inspection is given to this detail.

Recessing the Base

Three Bullard single purpose machines are used for cutting out the recess to receive the base plate. A view of this operation is shown in Fig. 14. This view with the chuck guard thrown back gives a better idea of the chuck extension shown in Fig. 6.

Two methods of inserting this base plate are now being used—screwing and riveting: the latter at present being more generally adopted. Each machine is recessing about 150 shells in ten hours.

The base plates are finished in two Greaves Klusman 20-inch engine lathes.

Riveting in Base Plates

Fig. 15 is a view of the operation where the base plates are riveted in and faced off. Two C. M. C. 18-inch engine lathes, fitted with special chucks, are used on this operation. While the cutting tool is facing off the base plate from the rear (the lathe running backwards),

the Independent Pneumatic riveter is operating on the opposite side of the disc. One man on each machine faces off and rivets 150 in ten hours.

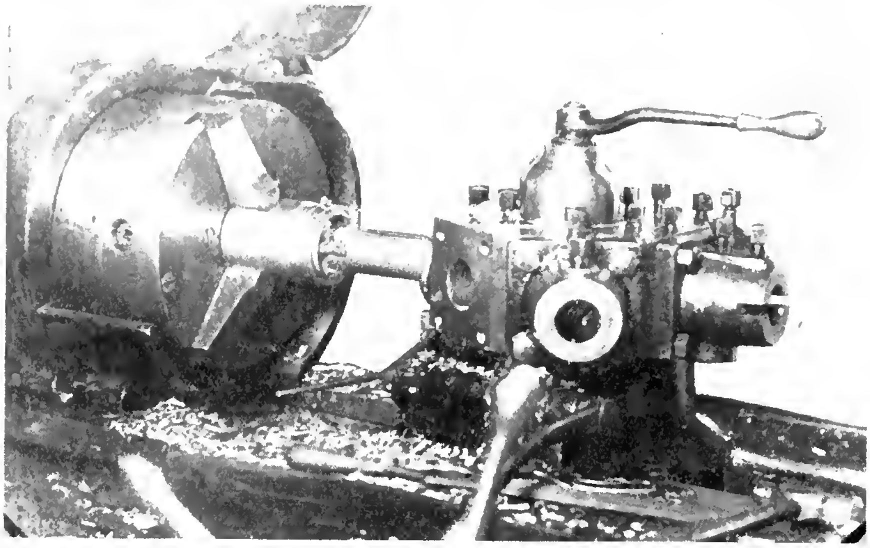

FIG. 14. SINGLE PURPOSE LATHE RECESSING SHELL BASES.

Purpose of Base Plate

The uninitiated may wonder why the metal at the base of the shell is first taken out and a plug inserted in the space, for no apparent reason. However, in the general construction of high explosive shells this feature is one of the most important. During the process of casting the ingot and forging the shell there are always possibilities of the formation of pipes and flaws. When the gun is discharged the propelling gases exert such a pressure on the base of the shell that any defects at this point might allow these gases to penetrate the metal and ignite the explosives contained in the shell, causing a premature bursting of the shell, and possibly destroy the gun and injure the crew.

For this reason a disc of close grained forged steel is inserted in the base of all high explosive shells of the smaller sizes.

Fitting and Machining Brass Socket

The brass or steel sockets—which come to the shop in a semi-finished state are now screwed firmly into the nose of the shell. This is accomplished by chucking the shell in an old lathe, and by means of a special jig the bush or socket is forced home. The jig is threaded on the outside to fit the bore of the bush. Through the middle of the jig is a slot which contains a tapered key, and back of this slot is a square to fit a suitable wrench.

To put the bush in, the jig is screwed into the socket and a threaded collar comes in contact with the bush. This collar is backed up by the tapered plug, which prevents the collar from turning. When the socket has been screwed firmly into place, a sharp tap on the small end of the locking pin releases the device and the jig is easily removed.

The sockets are finished turned (to conform with contour of nose) on an old engine lathe, fitted with a special head on the saddle, carrying a form cutter.

Pressing and Machining Copper Band

After the small hole (for the screw that secures the time fuse) has been drilled and tapped, the shells are taken to the banding machine, where the copper bands are pressed on. This is performed on a Lymburner hydraulic press receiving power from a pump of the same make.

FIG. 16. PAINTING SHELL BODIES.

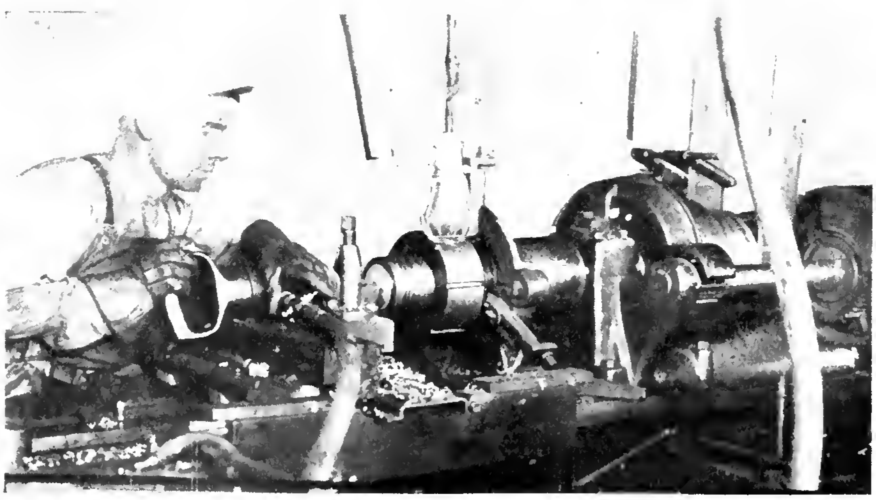

FIG. 15. RIVETING-IN SHELL BASE PLATES.

The copper bands are now finish turned to the desired form on a Jenckes band turning lathe, fitted with a special chuck, operated by compressed air. The cycle of operations are the placing of shells in the chuck; locating with a stop gauge; closing chuck; removing stop; turning band; removing burrs with hand scraper; releasing chuck; removing shell and gauging the band. An average output of from 90 to 100 per hour is maintained. On test, a production of two finished bands a minute has been done on this machine. The finished dimensions and profile of the copper band must

conform to the specifications as closely as possible.

Varnishing the Interior

The shells are now heated for about half-hour to a temperature of 250° F. in two special gas furnaces constructed by the P. Lyall & Sons Construction Co.

When sufficiently heated, the shells are transferred to a bench, where the internal surface is sprayed with varnish by using a sprayer made by the Paasche Air Brush Co. After varnishing, the shells are placed in an electric oven for about an hour to thoroughly dry and harden.

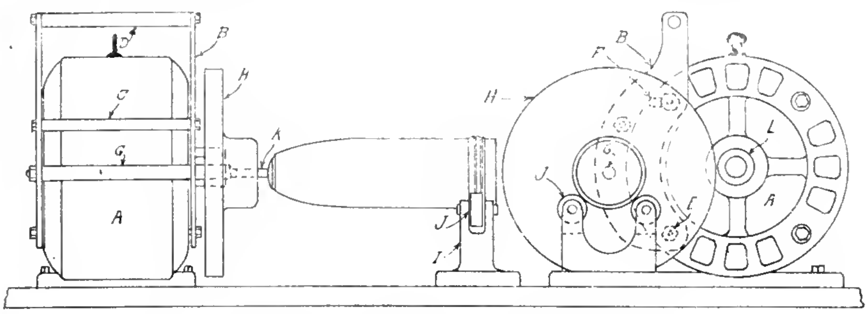

FIG. 17. DETAIL OF SHELL PAINTING DEVICE.

Each shell is now closely examined by Government inspectors, when all doubtful shells are set aside, and if these cannot be corrected to meet the specifications, the shells are rejected. The factory inspectors have become so thorough in their work that very few of the shells submitted to the Government examiners are rejected.

It might be well to state that the varnishing of the shell interior is a very important detail, and a smooth, clean, dry surface, free from cracks, flaws and other imperfections, is necessary, as the action of the explosive charge is very destructive to exposed metal.

Interesting Painting Device

A very interesting and productive revice is used in this plant for painting the outside of the finished shells. This arrangement is shown in Figs. 16 and 17. The power is derived from a ½-h.p. Thompson motor. On either side of the motor A are the plates B, held together by the stay rods C and D. This frame work is hinged at the stud E. On the shaft G is secured the wooden disc H and the chuck shown, which carries the driving pin K, squared on the end to fit the hole in the plug.

The bracket I is secured to the bench in such a position that the rolls J support the shell at the copper band, allowing access to all parts of the shell to be painted.

The shell is placed on the device with pin K in position and the frame B forced over with the left hand, bringing the discs H and L in contact, thus revolving the shell. The slot F prevents the frame from falling away from the motor.

Crating and Loading

When the paint has thoroughly dried, the shells are again inspected and crated, two in a box, in readiness for shipment. This last operation being performed on the second floor, the arrangement shown in Fig. 18 was constructed to facilitate handling of the crates from the shop to the car.

In line with the top of a bench A an opening was made in the brick wall and the shoot C supported as shown. The piece D, which is hinged at the base of the shoot, is supported by the brace E in such a position that the velocity of the case is reduced as it is received into the car. The piece D can be dropped clear of the track when the car is loaded. The present output is a carload of about 4,000 shells a week.

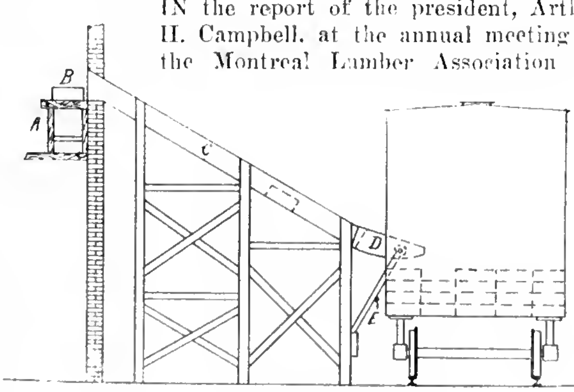

FIG. 18. SHIPPING THE SHELLS.

PORT OF MONTREAL LUMBER EXPORTS

IN the report of the president, Arthur H. Campbell, at the annual meeting of the Montreal Lumber Association recently, reference was made to the fact that, in spite of the very high ocean freight rates on lumber as a result of the scarcity of ocean tonnage brought about by the war, the exports from the port of Montreal will probably be found when the figures for the season are finally compiled, to have been quite as large as last year's. The demand has been chiefly for lumber such as spruce, and hard woods for the manufacture of cases and crates for war purposes.

The president referred at length to a large number of important matters in connection with railway transportation, chief among them being the proposed advance in railway rates on lumber in the territory east of Port Arthur, the last hearing in connection with which was held by the Board of Railway Commissioners on 30th June, no decision, however, having yet been rendered by the Commission. The association had strenuously opposed any increase in the railway freight rates on lumber.

CANADIAN ECONOMIC AND DEVELOPMENT COMMISSION

THE Economic and Development Commission, which has been in session in Ottawa during the past week, has adjourned to meet again in Ottawa the latter part of January, when it is expected that a very considerable mass of information bearing on its work will have been collected. The Commission is desirous of securing information on all matters within the wide scope of its inquiries, and invites communications from all authorities or experts dealing with such subjects as:

The collection and publication of accurate and reliable statistics relative to the agricultural production of the Dominion;

The inauguration of some comprehensive plan whereby farmers may obtain more readily and less expensively than at present long and short credits for the carrying on of farm operations and the further development of their resources;

The application of the principle of Government control to public markets, stock yards and other like utilities;

The whole question of co-operation in connection with the production, marketing and consumption, and the advisability of securing simple and uniform legislation providing for the establishing and management of co-operative societies;

The question of settling the vacant lands of Canada, and the future policy respecting immigration and colonization in this connection.

The Commission invites the hearty co-operation of the Canadian public in the work which it has in hand. Any person desirous of presenting written statements or appearing personally before the Commission will be accorded every reasonable opportunity of so doing. Communications should be addressed to the Secretary, 22 Victoria street, Ottawa.

Low Level Pumping Station, Montreal City Waterworks

Staff Article

The origin and development of this plant, which supplies the greater portion of Canada's metropolis with water for domestic and other purposes, is not only interesting, but serves to indicate in an impressive manner the constant and periodical growth of waterworks pumping equipment in a large city. The evolution of modern types of machines is clearly indicated.

THE main, or as it is usually termed, "Low Level" pumping station of the City of Montreal water works department, is probably one of the finest examples in this country, of the gradual modernization of an equipment that, while originally of ample capacity for the purpose for which it was designed, was forced to keep pace with the unprecedentedly rapid growth of our largest city.

The water supply was originally drawn from the St. Lawrence river, at a point 5½ miles above the plant and some distance above the Lachine Rapids, through an open canal which gave a head of about 20 feet at the present location, where a dam and hydraulic development furnished sufficient water-power to pump enough water for the Montreal of the fifties and early sixties.

In 1868 when the limits of the water power had been reached, the first steam installation was made, as an auxiliary to the hydro-power station, and an addition of 10,000,000 gallons to the daily capacity was deemed ample for years to come.

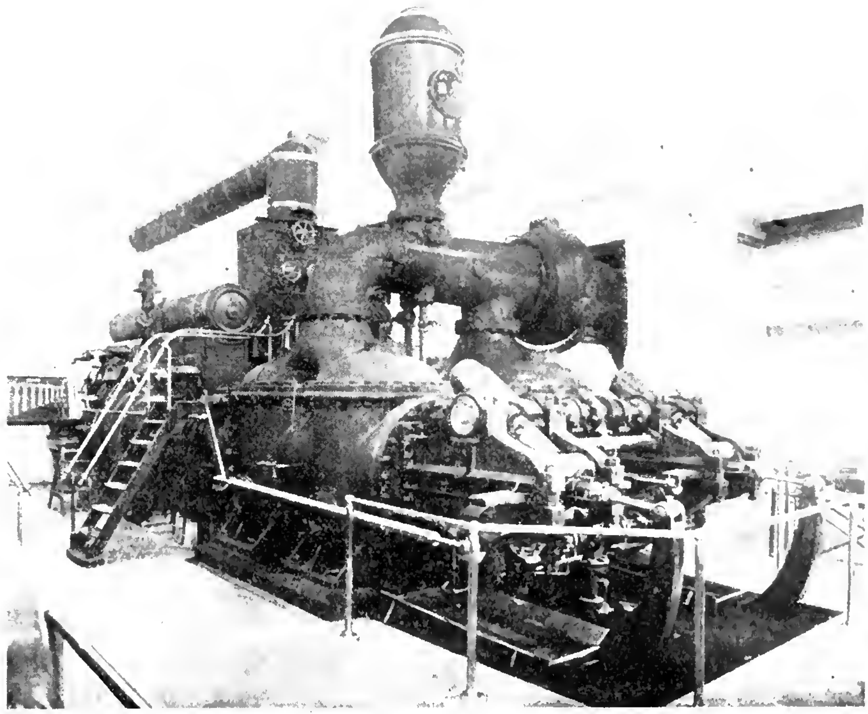

FIG. 2. WORTHINGTON DUPLEX HIGH DUTY STEAM PUMP.

In the eighties began the real growth of Montreal which was so much more rapid than anticipated, that from 1893 the authorities found themselves called upon to furnish water each year to from 20,000 to as many as 45,000 additional new inhabitants; a condition that had been almost impossible to foresee, until at present the municipal service is capable of furnishing a population of 750,000 souls.

FIG. 1. LOW LEVEL PUMPING STATION, MONTREAL CITY WATER WORKS.

Looking at Fig. 1, there will be seen at the extreme right, the end of the old hydraulic plant, which is soon to be demolished to make room for the new projected hydro-electric station, when the old canal had been widened, deepened and concreted. The next building to the left contains the first auxiliary steam units, and the other buildings contain the additional equipment which to-day constitute one of the most complete and economically operated pumping plants on the continent.

Pumping Equipment

The plant from the very nature of its growth exhibits in itself a most interesting history of the development of pumping machinery during the past 50 years.

No. 1 pump, which is not shown in our illustrations is still in active service, and No. 2, which is seen in Fig. 2, is a pump furnished by the Worthington Pump Co. to supply water for general purposes at the Columbian Exhibition

in 1893. This pump with a capacity of 8 million gallons per day was at that time the last word in economy and efficiency, and brought to its builders the Grand Prize in competition with the whole world.

It is most interesting to turn to Fig. 3, a photograph of a De Laval turbine driven centrifugal pump of 30,000,000 gallons capacity, which has just been installed. This unit is driven by a multi-stage De Laval steam turbine which develops 1,800 horse power when running at 3,600 revs. per min. The power from the turbine is transmitted to the pump by double helical gears which revolve the pump at 600 r.p.m. The steam turbine exhausts into a Wheeler condenser, which maintains a vacuum of 29 inches. The condensate is pumped by hot well pump through an auxiliary heater in condenser head to an open type Cochrane heater, which reheats the condensate to a temperature of 210 degrees Fahr., by means of low pressure steam taken from low pressure stage of turbine.

After leaving the heater, the water is passed through a Cochrane type V notch recording meter to the feed pump, which returns water at steam temperature to the boilers. The hot well pump is also driven by steam taken from low pressure stage of turbine.

In the background of Fig. 3 may be seen the "Columbian" pump, and the progress in pump design, during the past 30 years could not be better illustrated.

Fig. 4 illustrates the intermediate stage of pump design, being a "McDougall" centrifugal pump, direct connected to a "Browett-Lindley" high-speed triple-expansion engine, and of this type, there are four pumps in plant.

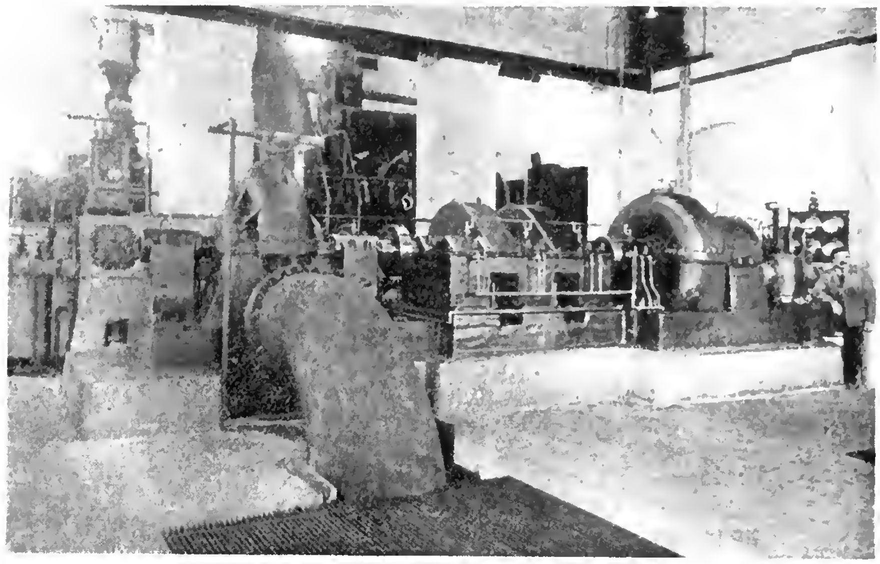

FIG. 3. SINGLE STAGE, 30-IN. DE LAVAL TURBINE PUMP DIRECT CONNECTED TO DE LAVAL MULTI-STAGE, 1800 H.P. IMPULSE STEAM TURBINE.

The total pumping capacity of the present equipment, pumping against a head of 210 feet to the lower level reservoir above McGill University is as follows.

1	Worthington	10	million gals. per 24 hours
2	Worthington (Columbian)	8	" " " " "
3	Jno. McDougall Caledonia Iron Works	12	" " " " "

Boilers

The boiler room like the pumping station shows the same evidence of expansion and modernization. The original pumps were designed to operate at 110 pounds steam pressure, and the boilers that served these pumps were operated at this pressure. With the newer pumping machinery came engines requiring higher pressures, and with the exception of six old boilers that are used for the two oldest pumps, steam pressure is carried at 150 pounds, with 100 degrees of superheat.

The principal units in operation are, 6 Heine; 3 Caldwell; 3 Robb-Mumford; 2 Howden; 1 Canada Foundry; 4 Wicks, three of the last mentioned are of vertical type and all the others are horizontal water tube boilers. The most recent equipment consists of the three vertical Wicks, 350 h.p. boilers; and last but not least is the 500 h.p. horizontal Wicks, shown in the foreground of Fig. 5, which is a view of the north side of the boiler house.

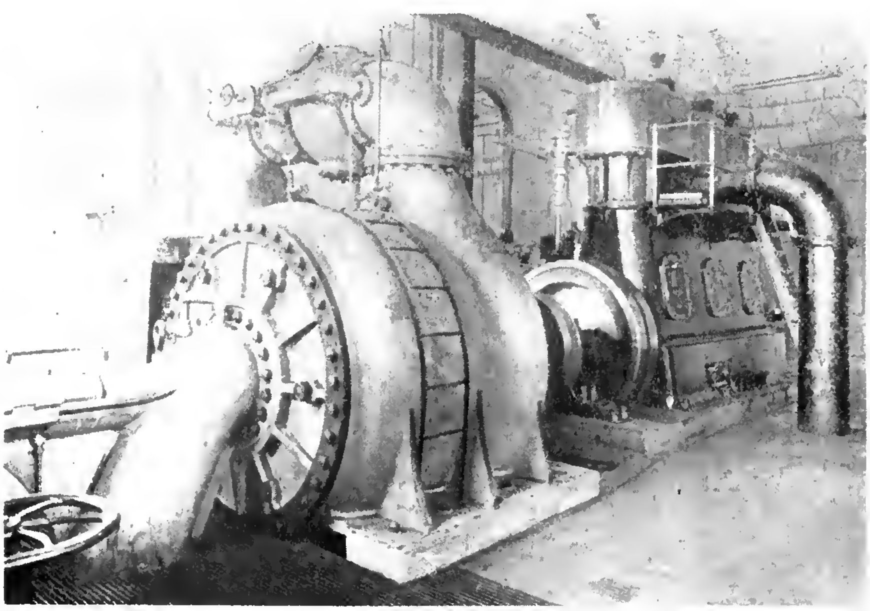

FIG. 4. THREE-STAGE, 20-IN. McDOUGALL TURBINE PUMP DIRECT CONNECTED TO 750 H.P. BROWETT-LINDLEY VERTICAL TRIPLE EXPANSION, QUICK REVOLUTION ENGINE.

Fuel and Combustion

Bituminous coal was the fuel used for many years, but owing to smoke for which the plant was formerly somewhat notorious it was decided to use small anthracite "Bird's Eye" coal mixed with 15 per cent. bituminous slack.

Forced draught is used, with special grates, and the results have entirely justified the change. The estimated saving by using the cheaper grades of coal is about $40,000 annually, and with the exception of a few minutes, when cleaning fires, there is never more smoke than is shown in Fig. 1.

Every car of coal, when delivered at the plant, is sampled, and tested at the water department laboratory by the

chemist in charge with a Per Se mechanical agitator to determine condition as to size and dust, and is also analyzed for efficiency, or the number of British Thermal Units contained per pound of coal.

Each smoke flue is connected by means of ⅛ inch brass tubing to a room behind the boiler house where gas samples can be conveniently drawn from any boiler flue and analyzed. This practice is of great value in determining the state of efficiency at which the plant is being operated.

The forced draught equipment consists of undergrate blowers. Some of the boilers are equipped with steam jet blowers and special grates supplied by the Cotton Furnace Corporation, Newark, N.J.; three units with a similar system installed by J. W. Lamoureux of Montreal, while the last 500 h.p. Wicks' unit is equipped with a Coppus Turbo Blower and special grates supplied by H. L. Peiler & Co. The Coppus blower is seen in the right-hand foreground of Fig. 5.

All the forced draught is automatically controlled by Mason No. 4 damper regulators, operating special cone-seated balanced valves, which give extremely close and accurate regulation and were furnished specially for this service by H. L. Pelier & Co.

Auxiliaries

As all the pumping engines are run condensing, there is very little exhaust steam available for heating the feed water. The only exhaust available for this purpose at atmospheric pressure is from the engine of a high-speed electric light set of 40 horse-power, also from the exhaust of the boiler feed pumps, only one of which is in operation at a time. To overcome this difficulty and utilize any available heat losses, two closed feed water heaters are connected to the exhaust line of Nos. 3 and 4 pumping engines between the engine and the condenser. The exhaust steam is under a vacuum of 28 inches at this point, but the feed water heaters absorb sufficient heat from this exhaust steam to raise the temperature of the feed water to from 90 to 100 degrees F. or practically to within 10 degrees of the temperature of the exhaust steam at the relative vacuum.

The cold water from the mains is pumped through these two heaters to a third smaller unit in which all the available atmospheric exhaust is condensed, yielding a final temperature of from 160 to 190 degrees according to the load. The heaters used in this case are of the Reilly multicoil type, and were supplied by H. L. Peiler & Co.

This is said to be the only case in Canada where exhaust steam at a high vacuum is used for this purpose, and the estimated economy is about $12,000 per annum.

The two feed pumps are of the duplex type made by the Deane Pump Company of Holyoke, and were supplied by the

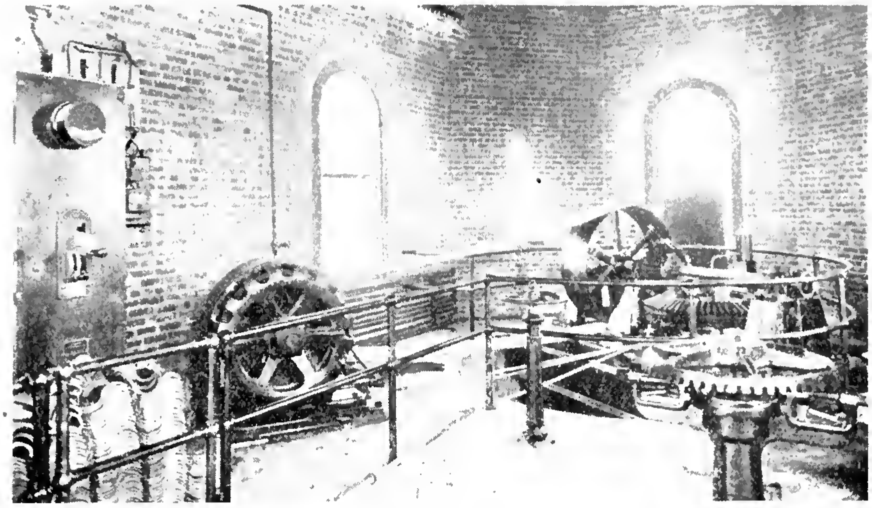

FIG. 6. LOW LIFT McDOUGALL SUBMERGED CENTRIFUGAL PUMP, BELT-DRIVEN FROM A 75 H.P. WESTINGHOUSE INDUCTION MOTOR.

FIG. 5. NORTH SIDE OF BOILER ROOM SHOWING COAL AND ASH HANDLING EQUIPMENT.

John McDougall, Caledonian Ironworks, Montreal, and Ross & Greig, Montreal.

All high pressure drips such as those from the steam separator, the steam mains at each end of the plant and from the steam jackets of the cylinders of Nos. 1, 2 and 4 pumps, are drained by Bundy traps discharging to a closed receiver in the boiler room from which they return automatically and under pressure through a No. 124 Bundy return trap direct to the boilers.

As No. 1 and No. 2 pumps are designed for low pressure, this is reduced from 150 lbs. to 110 lbs. by a Mason standard reducing valve.

The boilers are equipped with automatic feed control of the Berry & Williams type and the feed pumps are controlled by Mason pump pressure regulators.

Emergency Station

In case of any unforeseen accident, whereby the supply from the river should be cut off, an emergency conduit from the Lachine Canal has been installed. The fall from the canal to the plant is sufficient to supply the pumps, but it was deemed advisable to install machinery to raise the water to a height of about 6 feet.

Two similar units with a capacity of 40,000,000 gallons per day have been installed for this purpose. One of these is shown in Fig. 6. These are of the low lift submerged centrifugal type and were installed by Jno. McDougall, Caledonia Iron Works.

About six years ago, the control of the technical branch of the water works department was placed entirely in the hands of the Engineer-Superintendent, and marked changes were made in the whole operation of the plant.

The entire credit of the modernization of the pumping and boiler equipment is due to Mr. T. W. Lesage, the present superintendent, who has been ably supported by Chief Engineer E. F. Valiquet and Second Engineer J. Maconomy. It is a noteworthy case of the complete rehabilitation of a plant that was formerly a by-word for inefficiency, and which to-day ranks as one of the most efficient steam plants on the continent.

To Treat Zinc Ore.—The zinc industry in British Columbia will receive a big impetus in the establishment at the Trail smelter of a large plant for treating zinc ore, to be operated by the Canadian Consolidated Mining and Smelting Co. The plant is expected to be completed by January 1. It will cost in the neighborhood of $1,000,000. The owners are mostly C. P. R. directors.

CANADA'S DEBT INCREASING

THE net debt of the Dominion has now passed the half-billion mark, being at the end of November $501,668,167, an increase of nearly ten millions during the month. This does not include the new Canadian hundred million-dollar War Loan, which will bring the net debt over six-hundred millions. This will be almost double the public debt at the commencement of the war, and will involve an annual interest charge of nearly thirty million dollars.

At the opening of the war, Canada's public debt stood at $331,873,814. The increase, therefore, not counting the new internal loan, has been, since the war began, $169,794,353. Of this, $127,265,431 is attributable to war expenditures, every cent of which has had to be borrowed. This leaves $42,528,922 to be accounted for by other borrowings.

Next Four Months 60 Millions More

War expenditure for the year ending March 31, 1915, was $60,750,476. For the first eight months of the present fiscal year it totalled $66,514,955. For the next four months, owing to the ever-increasing number of Canada's fighting men, and the necessity of providing them with extra winter clothing, another sixty millions will be added. The expenditure for November alone exceeded thirteen million dollars. At the end of the fiscal year, therefore, Canada's total war expenditure will have reached 190 million dollars.

For the fiscal year following, the Minister of Finance estimates that the expenditure will be $250,000,000, or $1,000 per man. Thus, if the war lasts until March 31, 1917, Canada's war expenditure will have totalled 410 millions, bringing the public debt, without taking into account the probable necessity of borrowing for domestic purposes, up to 800 million dollars, or $100 per head of population. The interest charges on this alone will be nearly forty million dollars annually, or three times the interest charge on the public debt before the war, and almost half the proceeds of the customs revenues of the Dominion during normal years.

Must Retrench

An annual expenditure for pensions of at least ten million dollars will bring the additional amount which Canada will have to pay from revenues every year as a result of the war up to at least fifty million dollars. At present Canada's total revenues are inadequate to meet her ordinary and capital expenditure without heavy additional taxation and borrowings. It is clear, therefore, that with an additional inevitable increase in that expenditure of fifty millions, retrenchment in other directions will have to be assiduously practised if the country is to be saved from a further addition to the enormous debt which she will carry, even should she be permitted to withdraw her armies from the field in the time mentioned above.

This year's domestic deficit will be less than it was last year, according to present indications. During the last fiscal year it totaled something over fifty millions. As compared with the first eight months of last year there is an apparent gross betterment during the first eight months of the present year of twenty-seven millions, made up of an increase of fourteen millions in total revenue and a decrease of thirteen millions in expenditure. In connection with the increase in revenues, customs accounts for about 8 millions, post-office receipts for about 3¼ millions and public works, including the State Railways, for about 3½ millions, there being a decrease in excise and miscellaneous receipts.

Merchants Replenishing Stocks

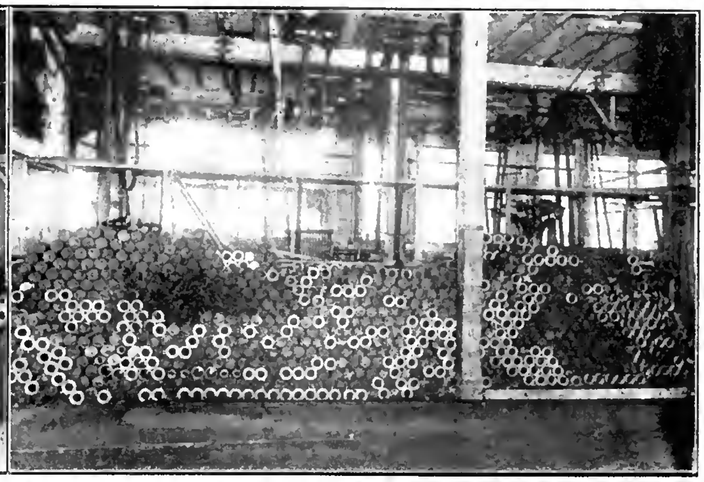
As an indication, for instance, that merchants are now compelled to replenish their depleted stores even in the face of a customs duty, which in October last averaged 36 per cent. on all dutiable goods imported. customs revenue for November increased by five millions over that for last November, or by over 100 per cent. How much of this represents duties collected on raw materials for war orders upon which a drawback will later be accorded when the finished product is exported, is not known.

The Government railways appear to be doing a gratifying amount of business this season, there being an increase in receipts for November as compared with November, 1914, of $1,800,000. The traffic carried this year on the National Transcontinental from Winnipeg to the head of the lakes, operated for the first time by the State, may account for a considerable portion of this increase.

Retrenchment Slight

The decrease in expenditures recorded for the eight months is accounted for by a retrenchment of ten millions in consolidated or ordinary expenditure and of three millions in capital expenditure as compared with the same period of the preceding year.

The turning over of a large part of militia expenditure to war appropriation accounts for six millions of the decrease in ordinary expenditure. Since the total expenditure for 1914-1915 (exclusive of war) amounted to 184 millions, an actual retrenchment of seven millions must be considered insignificant in view of the present world-wide financial situation.



New Machines and Appliances Evolved by Canadian Firms

Selected and Compiled

Not the least gratifying industrial feature of the past year has been the success attending the efforts of many of our shell makers to supply both their own and the needs of others at home and abroad in the matter of special machines and fixtures to accelerate and procure high quality munitions production. Many of these machines possess a permanent value and will therefore remain in service for years to come, practical mementoes of these times.

ALTHOUGH prior to the war most manufacturers were of opinion that machine tool builders had produced all of the various types of machines that were considered economically possible, it remained, in many instances, for firms with no pretensions as machine tool builders to fill not only their own demand but of others also, for tools of diverse requirements. As each requirement of the industry became known, it was quickly and efficiently sized up, so the necessary machines made their appearance, and the list of these which are briefly described below indicate more than anything else, the completeness of the grasp which our metal working plants have acquired of the entire work of projectile manufacture.

Cutting-off Machines

John H. Hall & Sons.—Their cutting-off machines have been redesigned and new models brought out which are adaptable to shrapnel and high-explosive shell work. The bed of the machine is heavily constructed and to it is bolted the headstock. The spindle is of serviceable dimensions and rests in ample bearings, the whole being entirely enclosed by a cast iron cover. The cut-off slide is provided with two tools, working in opposite directions, provided with power feed. Longitudinal travel to the tool slide is obtained by means of a screw and star-wheel conveniently placed at the end of the machine. These machines are driven by a pinion and spur gear, the power being received on wide-faced belt pulley.

Hamilton Gear & Machine Co.—A cutting-off machine designed and built by the Hamilton Gear & Machine Co. consists of a main bed casting upon which is mounted an annular chuck with automatic jaws, which grips the shell body leaving both ends exposed. The shell is placed in the chuck from the back, and is located by a stop rod, positioning from the inside base of the shell. Two tool-slides are provided, one on each side of the chuck, the slide at the back carrying a tool which removes excess metal from the shell base, while the front slide carries a cutting-off tool which trims the shell to correct length. The chuck is driven by means of a spur gear and pinion, the latter being keyed to the drive shaft placed at the back of the machine. A clutch pulley, operated by a hand lever, drives the shaft, ample belt power being provided for the heavy work required of it.

Single-Purpose Lathes

Canadian Fairbanks-Morse Mfg. Co.—Are building a manufacturing lathe of limited capacity(designed to meet the demand for a plain heavy standard lathe, which can be easily handled by non-skilled labor. The steel gearing is cut from the solid, and the headstock bearings are fitted with brass bushings and ring oilers. The lathe is regularly furnished with a solid spindle, having nose bored for No. 5 "Morse" taper centre. The carriage has power longitudinal feed only. Automatic stops control this obtained by means of a shifting lever in the gear box. The feed is positively driven by gears from the spindle, all gears suitably covered. The tool box is of the European type, of ample proportions, and has hand cross-feed only. Two speeds only are furnished by the 6-in. wide cone steps, which are of 11 and 14 inches diameter respectively. The bed is 7 feet long, very rigid, and allows 21 inches between centres. A maximum swing of 16 inches diameter is available over the bed, and 10 inches over the carriage. When desired, this lathe can be furnished with various attachments for different operations.

John T. Hepburn.—A plain lathe designed to insure speed and accuracy with unskilled labor. The bed is of rigid construction, with flat ways. The spindle is driven through a single belt pulley 13½ in. dia. x 8 in. face, with friction cone clutch. The carriage is simple in design and carries a solid tool box slotted to receive the tools. The carriage has power traverse, and is also provided with a double lever for moving by hand.

Heavy Duty Duplex Lathe

Canadian Linderman Co.—Two heavy hollow spindles triple geared on the nose avoiding torsion strains. No. 5 socket and face plate for chuck or special tools: two milling machine type carriages on heavy dovetail ways, provided with cross-slide or other special equipment for profiling, reaming, boring, drilling, facing, recessing, etc. This tool was brought out for 3.3, 4.5, and 6 in. high explosive shells by the Linderman Machine Co. for their United States and Canadian shops where they have forty-five in operation doing practically all operations on high explosive shells, except waving and threading milling, and as sixty per cent. of the operations require only one man to handle two shells, this machine has already fully demonstrated its ability as a cost reduction machine.

Expanding Chuck

R. McDougall Co.—An excellent type of expanding chuck is made with a hand-wheel fitted to a rod which extends through the hollow lathe spindle. Two sets of three jaws expand and tighten against the shell, which is pushed on the chuck until the end of the lathe, which acts as a stop, is in contact with the bottom of the shell. The jaws are caused to expand by two tapered lengths of the central spindle of the chuck. A stiff spiral spring, which acts as a means of adjustment, is placed between the two tapered portions. Thus as the small pair of jaws are designed to seize just before the larger, this spring allows the tapered portion of the spindle to continue to tighten the larger jaws. Flat steel springs withdraw the jaws from the work when the hand-wheel is turned.

Waving and Undercutting Attachment

John Bertram & Sons Co.—A fixture which may be attached to any style of lathe has been designed and built by the John Bertram & Sons Co. The shell is held in the chuck, to the face of which is attached a triple-face cam. The tool holders are bolted to the ways of the lathe, the front holder supporting the waving tools and the rear holder the left and right-hand undercutting tools Fastened to the lathe saddle are the two cam brackets. At the beginning of the operation the saddle is moved towards the headstock and causes the cam on the brackets to force in gradually both the front and back tool holders. The front holder is held up against the cam on the chuck by means of a spring. The cam imparts an oscillating motion and gives a wave to the ribs. At the same time the undercutting tools which slide in diagonal guides are forced in by two cams on the rear bracket, giving the desired angle to the undercut. A stop in the centre of the fixture regulates the depth of cut for all the tools.

Nosing Presses

Brown-Boggs Co.—A standard geared straight side press has been adapted for nosing light shrapnel shells. The shell is placed on the bed plate of the press, a support being provided to hold the shells in the correct position. A heavy nosing die is attached to the end of the ram; suitable ways or slides being provided in the sides of the press in which the die slides. This machine is also equipped with a four-point instantaneous clutch. Apart from being designed for the economical production of shells, it will also give good results as a general purpose press.

Canadian Locomotive Co.—The banding press made by this company can be equipped for the nosing of shells. All that is necessary to change the press over into a nosing press is to insert a steel plug in the centre of the machine. This plug is provided with a shank, which extends down and rests on top of the piston, from whence it gets its motion. A fixture is mounted on the centre of the machine, into which the nosing die is fixed. The shell is placed on the plug and is moved upward, the nose coming in contact with the die, which forms it to the desired shape.

Thread Milling Machine

Holden-Morgan Co.—A machine designed for the purpose of milling the thread in the base and nose of high explosive shells is proving very efficient, since it eliminates the risk of having the threads stripped. A casing, containing a hollow revolving spindle is supported on the left side of the machine bed. The inside end of the spindle is cone-shaped to take the nose, the spindle being self-centering. Power is supplied to the spindle through a worm driven by means of a pulley direct driven from shafting overhead. The outside centre of the spindle is threaded and a clamp provided to close over the thread when the spindle is required to travel horizontally. The milling cutter is held in a head which has no lateral motion. The shell is placed in the spindle from the left-hand side and secured. The milling cutter is inserted in the nose as far as the recess, and the cross-slide moved up to a graduated stop, which gives the required depth of thread. The spindle containing the shell is then made to revolve slowly, and at the same time travel horizontally outward or away from the cutter. The spindle makes one revolution, at the end of which an automatic stop is thrown out. The threads are now cut and the shell removed.

Banding Presses

Canadian Fairbanks-Morse Mfg. Co.—A powerful hydraulic press for pressing the copper bands on shells is manufactured by this concern. The frame ring is heavily constructed, being made of steel and supported on a substantial base. The six pressure cylinders and plungers are of an ample size, the diameter of the cylinders being 9 inches. The shell is placed in the centre of the press, and the plungers with the attached die-blocks are brought up to the copper band, squeezing it into place under a pressure of 750 lbs. per square inch. Oil, which is used to transmit the pressure, is supplied by a high-pressure power pump. The entire control is by means of a small hand valve; a safety valve also being provided to prevent accidents.

Canadian Locomotive Co.—The pneumatic press which this firm has placed on the market is different in many respects from other apparatus mentioned. The press consists of a heavy bed plate, supported on three suitable legs, and beneath which is placed a large air cylinder. Slides are provided for the jaws, the faces of which are slightly corrugated horizontally. A toggle motion transmitted to the jaws from the pneumatic piston causes them to converge as the piston ascends, while gravity causes the piston to descend as soon as the air is released. This is done automatically by relief valve. The diameter of the piston on this press is 28 in., and the air pressure used is 100 lbs.

Chapman Double Ball Bearing Co.—A feature of the Chapman hydraulic banding press is that it may be used in any other capacity since the machine is a standard "Perrin," four-post vertical press. The banding attachment is supported on suitable legs secured to the lower or vertical table. The device consists of a circular plate with a hole of suitable size in the centre, to accommodate the shell. Eight segmental jaws are arranged to slide in suitable grooves on the upper side of the plate, their outer ends forming part of a cone, while the inner ends are curved to fit around the copper band. Suspended from the upper table of the press, is a hollow casting containing a hardened steel ring with a conical bore, into which the attachment is forced by the upward movement of the lower table. This action causes the segments to converge on the band and press it home in the groove. A total pressure of 50 tons on the ram is ample power for 18 pdr. shells.

Jenckes Machine Co.—In connection with the manufacture of shrapnel and howitzer shells a banding press has been designed and put on the market by this firm for the purpose of pressing the copper band into place in the grooved recess on the shell body. The machine consists of a base or stand which is a heavy substantial grey iron casting, with a raised portion on which a ring rotates. This raised portion is slotted for six steel plungers, which are machined to bear on wedge-shaped recesses in the ring. The inner dies which actually press the copper band are machined as one piece, and afterwards cut in six sections, these being loosely pinned to the plungers to keep them in their relative positions. The plungers are all returned after the movement of the ring by means of the springs shown. The main lever and the toggle lever are steel castings.

The whole arrangement is operated by means of a 12-in. air hoist cylinder, controlled by a four-way valve, which permits quick and positive action. The air hoist cylinder is riveted to the main base

in such a way that the cylinder carries the motion of the lever without any tendency to cram.

Lymburner, Ltd.—A hydraulic press designed to operate at a maximum pressure of 1,500 lbs. per square inch, has been put on the market by this firm. The press is heavily constructed throughout, being supported on a solid cylindrical base. The circular frame which is of cast steel, encloses six cylinders on the inner ends of which are hardened steel die-blocks or segments. Oil, supplied by a pressure pump, is used for operating the press. This oil passes through 3/8 in. pipes, and enters a space between the stationary pistons and the movable cylinders. As the pressure rises it is transmitted through the cylinder and die blocks to the copper band. Coil springs are provided which force the cylinders back after the pressure has been released.

Band Turning

Jenckes Machine Tool Co.—The bed of the lathe, is a heavily ribbed flat top casting supported on legs of a standard type. The spindle is a substantial hollow steel casting, finished all over, and is driven through a 22 in. by 8 in. clutch pulley. The clutch is of hard maple, cone type, and is operated by a compresed air piston, controlled by a valve. The chuck is also operated by compressed air and is of the draw-in type. The tool slide base is heavy and immovably clamped to the lathe bed. The front or roughing tool is fed in by a screw and hand wheel to a dead stop, leaving a light cut for the finishing tool. The latter is mounted to the rear and above the work, being so adjusted that it can pass down behind the shell and in passing shave the band to size. The feed is by lever operating a pinion an d rack. The tools on this machine can be removed for regrinding and be replaced with precision.

Lymburner, Ltd. — The Lymburner band turning attachment which produces excellent results in finishing copper bands, consists of a rigidly constructed frame, which is secured to the ways of the lathe in use, in the required position. A single point roughing tool is fed by means of a hand wheel, in a direction parallel to the shell. At the same time as this tool is roughing the band, a slide holding the forming tool is advancing towards the work, being fed by means of the same hand lever and spindle as the roughing tool. When the roughing is finished, the forming tool enters and shapes the band. An upright slide, at the back of the device holds the finishing tool, which is forced down by means of a rack and pinion operated by a hand lever. This tool shaves the copper band to the correct size.

Mechanical Plug Wrench

Holden-Morgan Co.—A machine of entirely new design, for screwing home the plugs in the base of shells has been developed by the Holden-Morgan Co. The bed of the machine is a hollow iron casting supporting two spindle bearings and a table for the vise. A large spur gear is keyed to the end of the spindle and is driven by a pinion on a clutch shaft placed at the side of the bed. The chuck on the spindle is made to take the square end of the base plug. The plug is entered in the base recess, and the shell then placed in the vise with the square end of the plug in the chuck. A foot lever draws the spindle and chuck back at the same time forcing the shell towards the chuck. The clutch at the side is then thrown in, the spindle revolves, screwing the plug into the shell base. A spring forces the spindle towards the shell, following up as the plug enters. When the plug is driven home, the tension is thrown back to the clutch which slips. The friction device on the clutch is adjustable and can be set to any desired tension. The machine as a whole is of simple design and construction, and contains very few parts that can get out of order.

Shell Marking Machines

Brown-Boggs Co.—The mechanical device employed in marking the base of shells, in the machine here described varies somewhat in principle from the majority of marking machine being so arranged that the pressure is exerted on each individual letter and figure successively. The bed of the machine is similar in form to that of a lathe, on one end of which is supported a driving spindle with the revolving pressure chuck. On the opposite end of the machine is the saddle with a clamping device for holding the shell. The operation is very simple. First, the marking collar, in the base of which are inserted the desired letters, is placed over the end of the shell and secured by a thumbscrew. The shell is then clamped in the saddle, and is moved up to the pressure chuck by means of a handwheel. As the chuck revolves two inserted rollers in the face force each successive letter and figure into the base, the depth of the impression being increased or decreased as desired by moving the work carriage to or from the pressure chuck.

Shell Marking Machines

Holden-Morgan Co.—A compact and accurate machine for marking shells consists of a main base casting with two heavy uprights and a cross-piece, between which the shell is supported on rollers. A marking wheel with inserted letters and figures is held in a hollow bracket placed between the two uprights; one end of the bracket being pivoted. In operation the shell is placed on the rollers, and the bracket with the inserted marking wheel is forced down by means of a screw which is threaded through a central boss on the cross-piece. An oscillating or rocking movement is imparted to the marking wheel by means of a pinion and gear with the necessary crank attachments. As the marking wheel is forced on to the shell it also causes the shell to roll backward and forward on the rollers till the necessary impressions are made. When the shell is marked the screw is released and the bracket forced away from the work by means of a heavy spring. Power is supplied to the pinion by means of a belt and pulley.

Painting Machines

Canadian Fairbanks-Morse Mfg. Co.—The following painting machine consists of an upright standard secured to the base by stays and which carries the revolving table and operating mechanism. The table contains six sockets driven by means of a motor secured to the base casting. The belt from the motor is carried over two guide pulleys to a horizontal wheel. Attached to this wheel is a sprocket wheel connected by chain drive to a similar wheel on one of the spindles of the rotating sockets. On this spindle is a smaller sprocket, connected by an endless chain to a similar wheel on each of the other spindles. By this arrangement all the spindles revolve at the same speed, i.e., about 250 r.p.m. The shells are now placed in the sockets, nose down and revolve independent of the table. Stands for the paint cans are provided, so that two men can work at one time. The machine is portable, and so can be taken to the work without difficulty.

Canadian Locomotive Co.—An interesting type of painting machine is made in the shape of a huge drum, on the top of which is mounted a circular table resting on five rollers, three of which are made of laminated leather and impart a revolving motion to the table. Mounted around the outer edge of the table of the machine are sixty hinged bolts. The brass sockets, which are screwed into the shell nose, are then slipped over the bolts, nose down. A bracket to carry the paint can is slipped over the central stationary spindle of the machine, and can be moved around to any desired position. The operator swings the shell inward, upon the hinged bolts. This causes the bevelled surface of the brass casting in the shell nose to come in contact with the large central revolving disc. The shell is thus rotated and the paint applied with the greatest ease. Steam coils are placed in the centre of the machine, which permits the shells to be dried very quickly.

Marine Terminal of the G.T.P. Rly. at Prince Rupert, B.C.

Staff Article

The construction and installation of a floating drydock, together with a shipbuilding and ship repairing plant at the Western Terminal of the Grand Trunk Pacific Railroad, constitute an engineering achievement of no mean magnitude. Aside, however, from the latter feature, the establishment of such a combination plant is indicative of the far-seeing policy pursued and developed by the railroad management relative to its Pacific Coast shipping.

THE primary consideration in the development of this drydock undertaking was the isolated geographical position of the town of Prince Rupert from the nearest supply base, some 600 miles.

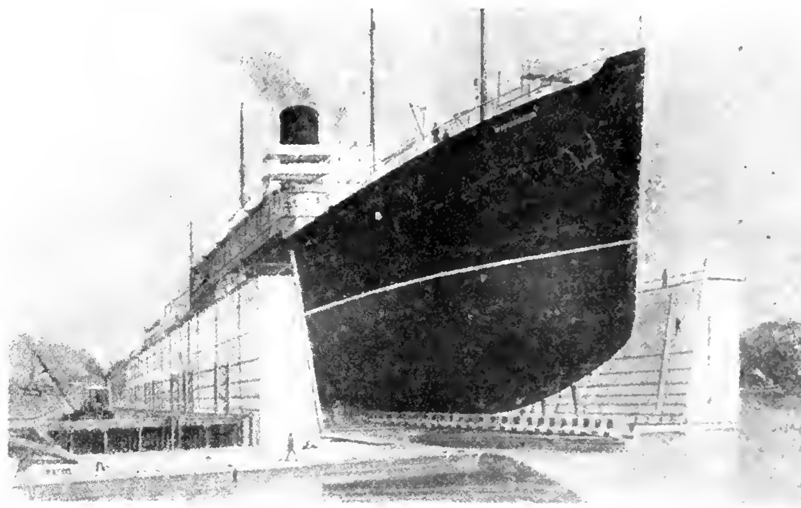
To facilitate the erection of the complete plant, the structures first built were utilized in constructing the remaining buildings and docks. The first work to be completed was the pier and launching platform, followed by the erection of the power house and the installation of the necessary equipment. After the completion of the engineering and administration buildings, the final work of constructing the 20,000-ton pontoon floating dry dock was successfully accomplished, and the operating machinery erected in position.

A general view of the shipbuilding plant and dry dock, and the latter with a large vessel aboard are shown on this page, and serve to indicate the plant capacity.

The opening of the new dock is an event of much importance, not only to the town of Prince Rupert, but to the many shipping interests in British Columbia and adjoining territory.

Floating Dry Dock

The entire dry dock, with a total lifting capacity of 20,000 tons, is composed of three distinct and separate, but interchangeable units. The centre unit of six pontoons, with an overall length of 269 feet, is capable of raising and supporting a vessel of 10,000 tons; while each end section, of three pontoons, and a length of 164 feet, will carry a weight of 5,000 tons. These pontoons are united by steel side walls or wings, 38 feet high, 15 feet wide at the bottom and 10 feet wide at the top.



THE NEW FLOATING DRYDOCK WITH A LARGE VESSEL ABOARD.

The structure as a whole is secured to the pier by the engagement of clamps on the dock with a vertical truss, secured to the pile platform in such a way that it is free to rise and fall with the tide (which in the spring is often 25 feet), and when being raised or lowered with a vessel aboard.

When it is desired to use the dock in separate sections, the forward three pontoons can be detached and moved around the corner of the pier and located alongside the platform. To use the remaining portion as two separate docks, the middle section of six pontoons is detached from the rear section and moved forward the length of the front section, and secured in position. The sliding clamps are so arranged that whether the

VIEW OF G.T.P. MARINE TERMINAL, PRINCE RUPERT, B.C., SHOWING HARBOR, FLOATING DRYDOCK AND WORKSHOPS.

dock is used as separate units or complete, the attachments on the pier will coincide with those on the floating dock.

Each pontoon is of timber construction, 130 feet by 44 feet by 15 feet deep, with a crown of 3 inches at the centre, and having 15 trusses spaced on 3-foot centres. A water-tight bulkhead, 12 inches thick, runs below the keel blocks of each section, and partial bulkheads on each side are used to strengthen the structure. The entire dock is made water-tight by caulking with white pine wedges, and protected from toredo and other marine worms by a coating of tar and gravel, poisoned with arsenic. Over this are two layers of hair felt, similarly treated, and covered with creosoted lumber secured with galvanized nails.

Pumping Machinery

The operation of lowering and elevating the dock is accomplished by twenty-four 12-inch centrifugal pumps, one in each end of each pontoon. The pumps on each side of the three sections are connected by a vertical shaft and gearing with a horizontal shaft to a motor placed on the top of the pontoon wall. Two 200 h.p. motors are used on the centre section, and the pumps on the end sections are operated by four 100 h.p. motors, one on the wall of each section.

The motors are alternating current, 3-phase, 25-cycle, 550-volt, with wound rotors and slip rings for variable speed control. The armature operates at about 500 revolutions per minute, and drives the pumps through reducing gearing at 275 r.p.m.

Workshops and Their Equipment

All buildings are of steel frame construction, with roof and floors of reinforced concrete; the walls of the power plant are also of reinforced concrete, those of the other buildings being, in addition, covered with wood. The entire equipment is of the most modern type, and machinery installed is capable of handling the heaviest and largest repairs that may be required upon any vessel operating on the Pacific Coast.

In laying out the general plan for the present site, the possibility of future shipbuilding developments was carefully considered, and, while the construction of steel vessels will not materialize for some time to come, it was nevertheless deemed advisable to construct buildings of a permanent nature.

The broadside system of launching has been provided for.

Pier Derrick

An interesting feature in connection with this terminal is the pier derrick shown here. This crane has a hoisting capacity of 50 tons, and is capable of taking care of the removal or installation of the heaviest pieces of machinery from or to the hold of vessels in Northern Pacific waters. It is also used for the unloading of material from vessels lying at the dock to cars upon the pier. Drydock and plant features are given in brief as follows:—

Type of dock—Floating.

Built by Grand Trunk Pacific Railway Co.

Location—Prince Rupert, B.C.

Estimated cost—$2,500,000.

Capacity of dock—Two sections of 5,000 tons each, 1 section of 10,000 tons; total, 20,000 tons.

Drydock Dimensions

Overall length on dock keel, 604 ft.

50-TON PIER DERRICK.

Clear width, 100 ft. between walls.

Width overall, 130 ft.

Number of lifting pontoons, 12 only.

Length of each, 130 ft.

Width of each, 44 ft.

Depth of each, 15 ft.

Buildings

Iron and brass foundry, 75 x 150 ft.

Machine shop, 75 x 150 ft.

Boiler and blacksmith shop, 75 x 150 ft.

Shipbuilding shed, 160 x 300 ft.

Power house, 104 x 148 ft.

Side launch platform, 440 x 80 ft.

Chimney on power house, 175 ft. high, 11 ft. diam.

General

Quantity of lumber in 12 pontoons, 4,000,000 ft.

Quantity of galvanized fastenings in pontoons, 400 tns.

Weight of each pontoon, 490 tns.

Lifting capacity of each pontoon, 1,700 tns.

Quantity of bolts and spikes, 360 tns.

Quantity of steel in wings of dock, 2,400 tns.

Number of rivets used in dock, 500,000.

Number of 12-in. centrifugal pumps, 24.

Capacity of each per minute, 5,000 gallons.

Time required for pumping entire dock, 1½ hours.

Quantity of paint used on wings, 13,000 gals.

Quantity of fireproof roofing used, 130,000 sq. ft.

Quantity of lumber in wharf, 3,000,000 ft.

Quantity of piling in wharf, 268,000 lin. ft.

Quantity of filling, 303,000 yards.

Area of yard, 20 acres.

Length of ship that can be docked, exclusive of overhang at bow or stern, 600 ft.

Width of ship which can be docked, 95 ft.

Maximum draft of ship that can be docked, 30 ft.

The power house contains two 1,000 k.w. turbo-generators and a large air compressor. A system of underground electrical conduits has been installed throughout the shipyard, as well as compressed air lines. The boiler room equipment will consist of six 400 horse-power water tube boilers, having automatic chain grate type stokers, such as are known to give satisfaction with Pacific Coast coal.

The ship-shed is provided with two 10-ton travelling cranes, and vessels can be constructed in this building under cover. The engineers who designed the dock and were in charge of construction are Messrs. Frank E. Kirby and Wm. T. Donnelly, of New York, J. H. Hillsbury, of Prince Rupert, acting as their local representative on the work. Chas. H. Crowell is general manager and superintendent of the dry dock.

LAKE FREIGHTERS SOLD FOR OCEAN SERVICE

TWO lake freighters of the type very much in demand have changed ownership. Both are steel vessels, which have been in the Great Lakes trade for several years. They are the steamers G. R. Crowe, of the St. Lawrence & Chicago Navigation Co., and the Algonquin, of

the Port Colborne & St. Lawrence Steamship Co.

The steamer Crowe, which has been sold to an English syndicate, will be converted into an oil tank steamer for Atlantic coastwise and Gulf of Mexico service. The work of remodelling the Crowe will be done at Midland, where she will winter. The sale price of the Crowe was not divulged. Lake ships are in great demand just now for the overseas trade, and it is announced that the Crowe brought a good profit to her late owners.

The G. R. Crowe was built in Dundee, Scotland, eight years ago for the St. Lawrence & Chicago Navigation Co., and is a steel steamer, 331 feet long, with a 43-foot beam, and a moulded depth of 26 feet.

The Algonquin is well known in Toronto harbor, and was one of the first steel steamers to be brought to Canada. She was built by R. Napier & Sons, Glasgow, Scotland, in 1888, for Thomas Marks & Co., of Port Arthur. The Algonquin, which latterly has been sailing under the flag of the Port Colborne & St. Lawrence Steamship Co., has been purchased by A. B. Mackay, of Hamilton, who recently negotiated the sale of the steamer Turret Chief to a British syndicate.

It is understood that the Algonquin will be remodelled for overseas service during the winter. She is a sister ship to the Rosedale, and has plied with uninterrupted success on the Great Lakes since her arrival from across the ocean.

LACHINE CANAL 1915 SEASON

FINAL figures regarding the Lachine Canal navigation season of 1915, show that 41,352,876 bushels of grain were brought down as against 67,343,952 bushels in 1914, a decrease of 25,991,076 bushels. Of all the grains, only corn showed an increase, the 702,736 bushels brought down this season being 592,803 bushels more than in 1914. Wheat showed the greatest decrease, the 30,443,678 bushels received being 19,445,565 bushels under last year's total. The other figures for this year, with the decrease in each case, are as follows: Oats, 8,499,035 bushels, decrease 3,690,542; barley, 1,276,810 bushels, decrease 2,937,673; rye, 23,135 bushels, decrease 250,087, and flaxseed, 407,482 bushels, decrease 260,012.

The total number of vessels which used the canal were 590, as against 615 last year, a decrease of 25; but their combined net tonnage this year amounted to 249,050, an increase of 19,795 tons. The total number of trips was 7,820, which was 1,229 trips less than in 1914. As a result, the total combined tonnage for these 7,820 trips only amounted to 4,110,579, or 879,393 tons less than in 1914. The total tonnage of grain and miscellaneous cargoes carried was 964,916 tons under the 1914 figures, the total for this year being 3,265,294. There were 63,294 passengers carried through the canal and down the rapids, as against 90,989 in 1914.

The statistics for the year also show the following balances of advantage for 1914: Let passes issued last year, 5,764, this year, 4,820; lockmasters' tickets up, 1,334 and 1,018; lockmasters' tickets down, 3,014 and 2,560; permits to pleasure craft, 312 and 187; coal, 1,138,738 and 1,070,138 tons, a decrease of 68,600 tons to harbor, canal basin and up the canal; trips made light for return cargoes, 3,418 in 1914 and 2,942 in 1915, a decrease of 476. Deducting the number of trips made light from the total number of trips made, the result shows that only on 4,878 occasions did vessels carry cargoes, as against 5,631 times in 1914.

Building Materials Carried

In building materials, lumber brought down from Ottawa for United States ports unexpectedly showed a considerable increase, 19,107,600 feet board measure, or 46,214 tons having come down this year. Also there were 41 rafts of 5,000 lineal feet each, making a total of 205,000 lineal feet, or 4,100 tons, which passed through to the harbor during the season. There were 48,297 tons of sand up from the harbor to the canal basin, a decrease of 17,416 tons, and 44,866 tons down, a decrease of 23,778. This makes a total decrease of sand carried as compared with 1914 of 41,194 tons.

There was an increase of 1,019 cords of pulpwood up to Canadian ports, the total amount being 23,759 cords; and a decrease of 5,459 cords to American ports, that total for the season being 137,951 cords. This makes a total decrease of 4,440 cords. No pulp went to Canadian ports at all this year, as compared with 1,600 tons in 1914; also 26,137 tons went to American ports this year as compared with 36,012 tons last year, making a total decrease of 11,475 tons.

The comparative figures for "up or westbound" traffic and "down or eastbound" traffic are as follows:—Number of trips, up, 3,864; down, 3,956; tonnage of vessels reported, up, 2,008,474; down, 2,102,105 net tons; cargo tonnage, up, 799,203; down, 2,466,091 net tons; number of passengers carried, up, 15,846; down, 47,448.

Seagoing Tonnage

The following figures indicate that though there was a falling off in the total tonnage passing through the canal, the American tonnage increased:—Canadian steamships, 178 in 1915, and 190 in 1914; American steamships, 46 of 52,651 net tons, as compared with 27 steamships of 26,270 net tons in 1914, Canadian barges, scows, etc., 215 in 1915, and 255 in 1914; American barges, 6, as against 9 in 1914; American canal boats, 145 of 14,683 net tons in 1915, and 134 of 13,206 net tons in 1914. Of the Canadian steamships reported, some 50 vessels with a tonnage of 58,702 operated in coastal and overseas trade during the season. Of the American steam vessels reported, 18 vessels, having a total net tonnage of 25,241, passed out for American ports in consequence of the law forbidding railways to own steamships.

Because of the million sacks of flour in the gift to the Imperial Government from the Dominion in 1914, this year's total for flour passing through the canal is 123,273 sacks, being 1,040,985 sacks under last year. The comparative figures for 1914 and 1915 respectively for produce carried through the canal are as follows: Eggs 14,909, and 14,465 cases, a decrease of 444; butter, 6,544, and 4,984 packages, a decrease of 1,560; cheese, 194,834, and 221,212 boxes, an increase of 26,378; apples, 30,448, and 25,131 barrels, a decrease of 5,317.

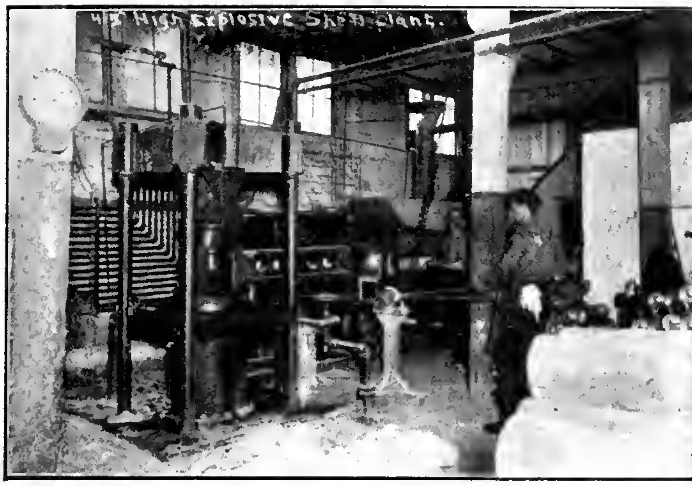
The first vessel down in the spring was the W. H. Dwyer, which was entered on the canal books on April 23, with 73,636 bushels of wheat, and the last boat through the canal was the Wylie M. Egan, with coal.

G. T. P. STEAMSHIPS

ACCORDING to information received at Grand Trunk Pacific headquarters in Montreal, the G. T. P. steamships operating in the North Pacific Coast waters have covered over eighty thousand miles during the season of 1915. This is considered one of the most remarkable records in the coastwise trade.

Running between Prince Rupert and Seattle the steamship "Prince Rupert," between June 8 and November 4, steamed 40,717 miles, almost twice the distance round the world. Her sister ship the "Prince George," covered 40,840 miles. The average distance run per day by these vessels was 395.86 miles, and the average speed per hour 16.49 knots. In order to keep their schedules, these steamships often steamed over 18 knots, reeling off better than 400 miles in a day. The steamships were timed to arrive at Seattle at 6.30 a.m. and 4 p.m., respectively—equal to any railway schedule.

Travel between North Pacific coast points remains fairly good and service is to be maintained between the Transcontinental trains of the company at Prince Rupert and the cities of Victoria, Vancouver and Seattle throughout the winter.



Typical Tools and Devices from Canadian Shell Shops

Selected and Compiled

The advent of shell making was signalized by a country-wide activity in designing and constructing the necessary tooling outfits for adapting existing plants to the new work. Great variety of thought has been evidenced in the production of special fixtures and operating devices, the all around excellence of which has contributed greatly to the success of our efforts.

IN visiting and describing the many plants engaged in projectile manufacture, numerous appliances are observed which, while of most immediate value to their present users, have more than a passing interest to machinists in general. A number of these are outlined herein and form a creditable record of initiative and resource.

Cutting Off Billets

Montreal Locomotive Co.—Planers were at one time used to cut the bars into billet lengths, but this method has now been discontinued. A very much similar arrangement is, however, employed on two large "Niles-Bement-Pond" millers. Clamping devices rigidly secured to the table hold 32 bars at one setting and eight large Disston cold saws cut off the billets. The travels of the table is completed in about two hourse, and when it has gone about half way, men at the rear remove the billets and set up another set of bars in their place, so that when the table has completed its travel the cutting arbor is raised and the table returned to commence cutting at the other end. The later cut billets are then removed and are replaced by bars, the cutting-off process being thereby almost continuous.

Facing Off Bases

John Bertram & Sons Co.—After the ragged open ends of the forgings are cut off, the bases are next squared up. This may be accomplished in a vertical boring mill by the use of a special fixture. The fixture is made of cast iron, being cylindrical in shape, with a heavy flange on the bottom, by which it is bolted to the table. On the outside of the cylinder is a series of lugs between which the forgings are clamped. In order to insure uniform thickness of the bases, the forgings are placed over, and rest upon studs of standard height, which are placed in the flange centrally between the lugs. The tool is fixed, being previously set to a gauge block. This fixture is capable of holding twenty forgings.

Canadian Fairbanks-Morse Mfg. Co.—A large 4-spindle "Ingersoll" milling machine is utilized to its full capacity, for machining the shell bases. The shells are held in fixtures, placed at each end of the table. These hold 28 shells in four groups of seven shells each, and are so arranged that the cutter heads come into action on their own group of shells simultaneously; the vertical heads projecting in advance of the side heads. The operation is practically continuous since while one group of shells is being machined the operator is employed at the opposite end emptying and reloading the other fixture.

C.P.R. Angus Shops.—The back ends of the forging may also be milled off on a vertical milling machine. A fixture, which accommodates these forgings is secured to the table. The forgings are pushed into the fixture, open ends first, until they come against a stop, and are then clamped securely by set screws. The table is moved into a stop, and then traversed by power, causing a solid milling cutter, 2½ in. in diameter, to pass over the face of the shell. It requires about two minutes to complete one base and the operation is practically continuous, as finished shells can be removed, and rough ones put in place while the machine is running.

Canadian Locomotive Co.—A "Newton" rod miller equipped with two special fixtures extending the entire length of the table is found to give continuous service for the work. After the ragged ends are cut off, the shells are placed in the fixtures; one clamp or strap, the inside of which is formed to fit the outside diameter of the shell, serving to hold two shells. Two cutters are used, each being eight inches in diameter, by 10 inches face, and having inserted teeth. As the finished shells pass under the head they are removed and rough blanks placed in the fixtures, while the machine is still in operation. When the table arrives at the end of its travel, the heads are slightly raised, and the table quickly run back to commence another cutting stroke.

Montreal Locomotive Co.—In facing off the bases of 4.5 shells a planer fitted up in the following manner is being used to advantage. A heavy forging having a series of V's or notches cut in it, is clamped to the planer bed. The shells are placed in the V's, three shells to each, and are gauged for length by having the shell noses "butt" against a bar fastened to the inside edge of the forging. They are then securely clamped by a heavy bar extending along the top. In machining the bases the side-head with vertical feed is used.

Centering Jigs

Canadian Ingersoll Rand Co.—For turning in the Lo-swing lathe with a mandrel, a centre must be formed on the back end of the shells, and this is done in a little drill press. A jig having an upright arbor, over which the shell is

placed, is secured to the drill table, and a hinged strap is placed over the top of the jig. A small drill, 5-32 inches in diameter, is run through the pilot hole, care being taken not to have this hole too deep because the back end of the shell when finished must have no marks on it. For this reason the drill is equipped with a stop. The hinged strap is then swung open and the shell and jig are shifted over under the second spindle of the drill press. A tool which forms the centre is carried in this second spindle.

Toronto Structural Steel Works.—An interesting design of centering jig which is rather simple in construction is giving excellent service. It consists of an upright arbor fastened to a block which slides in vees formed on the table of the drill press. A bushing, shaped to conform to the rough bore of the forging, near the base, slides on the arbor and is maintained in position near the top by means of a spring; the spring resting upon a shoulder formed by the lower part of the arbor. There is also provided another bushing, which is made a sliding fit for the lower part of the arbor, and is also held in its highest position by means of spring. This bushing is made with a suitable taper so as to rest half way into the open end of the forging. When the rough forging is placed over the arbor, it centres itself on the two bushings, which compresses the springs till the weight of the forging is taken by two stop pins. When the arbor is in its outer position in the vees, ample room is provided, clear of the spindle for placing and removing the shells. Centering is done by a combination drill and centre

Drill Jig for Shrapnel Noses

Alfred Herbert, Ltd.—A jig used in conjunction with a ball bearing drill press for drilling and tapping the small holes in the noses of the larger shrapnel shells, consists of a casting bored to receive a sleeve in which the shell is clamped. At the right hand end a small bracket and locating plug locate the nose. The jig is semi-automatic in its action. When the operator pulls a handle towards him the locking bolt is withdrawn, and on pushing it back the sleeve carrying the shell rotates until the bolt drops in again. This jig is exceedingly rapid in action and the whole arrangement very compact.

Expanding Mandrels

Canadian Ingersoll Rand Co.—An interesting type of mandrel used on an engine lathe, is one which is operated by air. A hollow arbor has a tapered shank to fit the lathe spindle, which is also supported and keyed to a casting fitted to the spindle nose. A plug screwed into the end of the arbor acts as a locating stop. Two sets of jaws are operated by means of a hollow sleeve and shaft similar to that used on the mandrel previously described. These sets of jaws are operated by a small air cylinder placed on the end of the lathe. When the air is turned on the piston is forced back in conjunction with the shaft and sleeve. The tapered portions on the end of these engage with the tapered jaws forcing them out against the wall of the shell. A retaining spring of suitable strength holds the jaws together and causes them to fall away from the work upon the return of the piston to its original position.

Canadian Locomotive Co.—The distinctive feature about the following type of arbor is its simplicity in design. The body, which is made of steel is turned to three diameters, being bored at the larger end to fit the lathe spindle, and counter bored, tapered and threaded to fit the rod which operates the jaws. The second diameter is turned so that the forging will slip over easily. To the smaller diameter is fitted a milled jaw which acts as a stop and locator. Three slots are milled near the inner end of the second diameter, and corresponding jaws made to fit. These jaws are operated as previously stated by means of a central rod which passes through the lathe spindle. When this is screwed in by means of a handwheel keyed to the outer end the tapered portion forces out the expanding jaws. When the rod is withdrawn a spring fitted to grooves turned in the thin jaws, causes the jaws to contract, leaving the forging free to be removed.

Chapman Double Ball Bearing Co.—In rough turning the shell body a specially designed mandrel for this class of work gives excellent service. The hollow arbor has three shoes at the front and three at the back which grip the forging at the base and nose respectively. A hollow sleeve, tapered on one end to engage with the rear set of shoes extends the full length of the hollow spindle of the headstock. A shaft which is mounted in the sleeve and tapered on the end to engage with the front set of shoes, extends throughout the length of the hollow sleeve, projecting past the end of the sleeve. The sleeve and shaft have left and right hand threads respectively cut on these outer ends, each with a handwheel threaded to suit, by means of which the shoes are tightened or released. A chuck, fitted to the lathe spindle, has a floating ring which is tightened on the nose of the shell and drives same.

Jenckes Machine Co.—When a boring mill is used for rough turning the outside diameters of shells a specially constructed arbor is required. One used on a "Bullard" mill is made with a heavy base by which it is bolted, centrally to the table. The body of the arbor is bored, and a small pilot or rod, tapered on the end to engage with a set of shoes, is made to fit. The shell is placed over the arbor and by means of an eccentric, placed at right angles to the pilot, the latter is forced up, causing the shoes to expand and grip the inside base of the shell. The nose of the shell is gripped by means of chucking arrangement similar to that used on a universal chuck, the jaws gripping the shell from the inside.

J. A. Moffat.—An expanding mandrel used in turning shells where the bore is parallel, is made as follows: A sleeve is turned to about .010 in. smaller than the bore of the shell, and a tapered hole, threaded at the smaller end is bored along its entire length to fit a tapered plug. The sleeve is split in the centre, thus allowing it to expand when the plug is screwed in. A round steel spring holds the two pieces of the sleeve together. The outer end of the plug is centred and has a square milled on it which fits a driver on the face plate. The threaded end is made, a standard pitch thread, which prevents the plug from pulling out when the sleeve expands.

Lymburner, Ltd.—Another type of mandrel has a flange which is secured to the face plate or chuck. A sliding collar or sleeve slips over the outside of the casting, and when this sleeve is advanced by means of a lever, three internal tapered slots act upon corresponding dogs. This action forces a hardened steel bushing forward and pulls the central rod backward. Tapered grooves formed on the bushing and end of the rod, force steel dogs, arranged in groups of three, outward, causing them to grip the shell. In releasing the shell, the sliding collar is moved back, and a spring acting on the bush and steel collar causes a relative movement between the bush and shaft, thus allowing the dogs to release their hold.

E. T. Spidy.—Since long holes are not always perfectly straight, a mandrel to average up the hole has been designed. It consists of a body threaded to suit the machine spindle, and bored out parallel. A spindle is fitted closely to this bore, which has a cotter fitted at the lathe spindle end. Corresponding slots are milled in the body to allow for the travel of the cotter. On the outside of the body two steel sleeves are fitted, then split in three sections, these being held together by a retaining spring. A solid sleeve placed between these, acts as a spacing block and transmits power applied by the centre spindle, through a nut and end bushing. By this method all the tapered faces act in unison, but

do not tighten up till both split sleeves are engaged with the hole.

Nose Bevelling Cutter

Toronto Structural Steel Works. — A tool for shaping the mouth of 4.5 shells preparatory to nosing was designed to be used in connection with a radial drill. It consists of a sturdy bar, a suitable tapered shank being turned on one end to fit the drill spindle. The other end is provided with a substantial pilot turned to fit easily in the bore of the shell. This allows the full power of the machine to be applied without causing excessive chatter. A slot is milled in the body of the bar to suit the cutter, which is of the flat double-edged type, bevelled to the correct angle. This is securely held by means of a tapered key. This key is left sufficiently long to project beyond the cutter, thus enabling it to act as a suitable stop.

Combination Reamer

Canadian Buffalo Forge.—A reamer for finishing the inside body, reaming the counterbore and roughing the fuse plug seat is used in a 20-in. drill press. The reamer is about 13⅞ in. long over all and has a taper shank for fitting into the drill press spindle. At the end of the shank the reamer widens out, and has slots for four fly cutters. These cutters are ⅜ in. square and have a bevelled cutting face for forming the fuse plug seat. The cutters are held securely in position by a ring with a set-screw for each. Under the set of cutters is a reamer for finishing the counterbore in the nose preparatory to being threaded. At the other end of the spindle, the exact distance away, is another reaming cutter for finishing the bore of the shell. The cutters are secured to the spindle by dowel pins. In operation, the bottom cutter starts at the top of the hole, and travels down with power feed, followed by the cutter above. When both have nearly finished their work, the four small cutters above begin the form of the fuse plug seat. This combination makes a very accurate and efficient tool.

Grooving, Undercutting and Waving

John Bertram & Sons Co.—Cutting the groove and wave is done on an ordinary engine lathe fitted up with a special fixture. One end of the shell forging is held in a chuck which has a cam attached to its face, while the other end is supported in a cup centre. The tool holders are secured to the lathe bed and the brackets, holding the feed cams to the saddle. The grooving and waving tool is held in the front holder, and the undercutting tools, left and right hand are held in the back holder. In operation the saddles move forward and cause the cam on the brackets to force in gradually both front and back tool holders. The front holder is held up against the cam ring on the chuck by means of a spring. As the cam revolves with the chuck it imparts a reciprocating motion to the tool which thus forms waves on the ribs. At the same time the back tool holders are forced in to undercut the sides, by the two cams, in a diagonal direction, obtained by the holders running on diagonal guides. A stop regulates the depth of all tools.

Canadian Locomotive Co.—These operations are performed on a C. M. C. lathe in the following manner: A tool post fitted to the back of the cross-slide holds a roughing tool which when fed in cuts the groove, roughing to width. This is withdrawn and a turret tool holder mounted on the front of the slide is brought into operation. The right and left hand undercutting tools, which operate in slides of the correct angle, are fed in by means of a cam shaft to the end of which is attached a hand lever. The cam is so designed that the tools cut to the finished depth and width just as the highest point of the cam is reached. The tools are now withdrawn and the turret swung around permitting a roller to register against a three-point face cam, attached to the face plate. By pressure of the roller against the cam plate, the necessary oscillating movement is communicated to the waving tool, which when fed into the finished depth, cleans up the bottom of the groove, and at the same time cuts the wave ribs.

Lachine Mfg. Co.—A device for undercutting the sides of the driving-band groove consists of a flat plate provided with two grooves machined to the proper angle, and in which slide two tool carriers. These have a number of rack teeth cut on their adjacent sides to engage with a pinion which when oscillated by a suitable lever, brings either tool in operation as desired. The tool carriers are made a close sliding fit in the grooves and are retained in position by suitable keeper plates fastened to the main castings. Adjusting stops are also provided at the outer end of each carrier to regulate the depth of cut.

A. B. See Elevator Co.—A special fixture used on a McDougall lathe shows a considerable amount of ingenuity in design. The main casting which comprises a roller steady rest and tool posts is bolted to the lathe carriage. The shell is driven from the nose end by means of a chuck, and is supported near the base by the steady rest, leaving sufficient room for the operation of the tools. The first operation after setting up is grooving, the tools for this purpose being held in the front tool post. A combination tool post at the back holds the knurling and undercutting tools. When the knurl is in position the undercutting is performed by two tools which are operated in slides planed to the correct angle.

Toronto Structural Steel Works.—An ordinary engine lathe equipped with a well designed combination turret tool box and the familiar cam ring on the chuck gives good service for these operations. The shell base is supported in a cup center and is driven by a plug centre in the nose end. The grooving tool is of novel design, being formed in two parts and is fed in to the required depth and moved to each side to form the desired undercut. A relieved portion in front of the tool allows for a sufficient amount of material to be formed into the waved ribs. A toggle arangement is secured to the end of the tailstock, by means of which a bar is caused to compress two springs which force the carriage against the cam ring on the chuck, thus imparting the desired reciprocating motion to the tool. A roller on the side of the carriage makes contact with the cam.

Thread Milling Attachment

Marsh and Henthorn—The converting of a universal grinder into a thread milling machine, demonstrates what may be done in the way of adapting standard machines to special work. All that is necessary is to mount a special head on the work spindle embodying a large bearing, which when bored and split makes a combination chuck and bearing. The necessary travel is given to the head by means of a fourteen pitch master screw, working in a nut of the same pitch. The arbor which carries the milling cutter is supported in the wheel stand.

Grinding Shell Bodies

Hamilton Gear & Machine Co.—The special holding arangement designed for use on a Ford-Smith grinder differs somewhat from that in other shops. The shell is mounted on centres, and is driven by gripping the nose end of the rough shell about where the shoulder is to be finished. This method of driving relieves the chuck of all strain due to the pressure of the grinding wheel. The live centre offers a firm support for the shell and conveys the grinding vibration directly into the frame of the machine. The reduction of noise due to this method is remarkable.

A. B. See Elevator Co.—The external grinding of shells is being accomplished by means of an old lathe fitted up with a taper attachment. A suitable casting is secured to the cross-slide, carrying the arbor and grinding wheel which is belt-driven from an overhead shaft. Brackets are fastened to the back of the lathe to

which is bolted a plate, with a cam attached, and shaped to suit the contour of the nose. A roller is held in contact with the cam by means of a spring on the cross-feed spindle.

J. H. Moore.—To make sure that all shell bases are of uniform size and finish there has been designed and built the machine herein described. It is what might be termed a special purpose grinder, being built for this work only. The work chuck is of the three-jaw universal type, allowing the shell to be quickly and accurately adjusted in position. The shell is gripped around the body just above the driving band, leaving the base end exposed. The grinding wheel is mounted between driving flanges on a spindle carried by a grinder head, which is arranged to slide crosswise on the carriage. This machine grinds two surfaces, as in addition to facing the base end of the shell, the wheel is used to grind the outside diameter of the base, thus necessitating a longitudinal motion by means of hand wheel and rack on the front of the machine.

Profiling Attachments

Canadian Fairbanks-Morse Mfg. Co.—After nosing, the shell is rough turned to profile with a flat forming tool. Following this it is chucked by the base, nose down, in a universal chuck secured to a drill press spindle. It is then forced down into a fixture which has three pairs of guiding rollers and also a flat forming tool for finish scraping the nose to shape. One pair of rollers is fastened on a gate, which opens to allow the shell to enter and leave the fixture. The action of this method is identically that of a huge pencil sharpener.

Hamilton Gear & Machine Co.—The profiling attachment here used varies somewhat from the usual arrangement. The templet is mounted on a rigid bar, which is securely fastened to the tailstock instead of the headstock, as in some cases, or the lathe bed in others. The adoption of this principle overcomes the necessity for locating the shell accurately in the chuck in relation to the templet, and also enables full advantage to be taken of the allowable variation in the overall length of the shell, so that when a shell comes through which is a little long, it is not necessary to remove any more metal than is necessary to come below the high limit; whereas when the profile copy is fixed rigidly to headstock or lathe bed, the tool will cut to the same point every time, unless the shell be adjusted in the chuck, which takes time, and is not so easily controlled as the method described.

Toronto Structural Steel Works.—An interesting attachment for use in profiling may be described as follows: A supporting bar is fixed to two blocks which are clamped over the front vees of the lathe bed at suitable points. A roller is mounted in a bracket fastened to the side of the cross-slide. By means of two powerful springs attached to the lathe carriage, the cross-slide is pulled forward keeping the roller in contact with the profile bar which is mounted on the supporting bar.

Drill Press.—A method of using the drill press for profiling is in connection with a hollow mill with inserted cutter. The cast iron body is provided with a taper shank to fit the drill spindle, and is bored out concentric with the shank, to the finished shape of the shell. The outside diameter is made considerably eccentric, the heavy side being cut away to allow the blade to be secured in the proper position. It is held in place by a clamping plate, which is formed with a heel, thus providing suitable support for the adjusting screws. This tool is used only for the finishing cut or scrape.

Driving Device

Toronto Structural Steel Works.—A driving device used in connection with a profiling attachment previously described, combines a driving plate and a method of locating each shell in relation to the profile copy. A cast iron arbor which is threaded to fit the lathe spindle is turned to a suitable diameter to receive an indexing plate, holding a spring plunger. The nose of the arbor has a left hand thread 2.6 in. diameter, which fits the driving plate; a spot being recessed on the back of this to receive the plunger. The point of the arbor is turned down and a hardened steel cap, threaded to fit the shell nose is provided. The shell is screwed on to the end of the arbor till it tightens against the edge of the driving plate, the left hand thread automatically locking the parts together. After the shell is machined, the plunger is removed from the driving plate, which is then slackened off by means of a wrench. When the shell is screwed off the arbor the driving plate is turned back to its original position, and locked by the plunger.

Copper Band Turning

John Bertram & Sons Co.—A simple method of machining the driving band is by means of two tool holders secured to the front and back of the cross-slide. A bracket is secured to the side of each tool box, which holds an adjustable set screw, which acts as a stop. The roughing tool is held in the back holder, and is fed in by hand by means of the cross feed handle, till the stop is reached. The feed handle is then reversed, causing the roughing tool to back out and the finishing tool held in the front holder to enter and complete the cut.

Canadian Ingersoll Rand Co.—Engine lathes equipped with suitable fixtures are extensively used in turning the copper bands. The shell is held in a chuck and located by a stop on the cross-slide. The roughing tool is held in an ordinary tool post and fed in to a stop, which determines the depth of the roughing cut. The finishing tool is held in a special fixture secured to the back of the cross-slide. The tool works in a vertical slide on the back of which is a rack. A pinion, operated by a hand lever, engages with the rack thus allowing the tool to be moved down across the back of the shell, shaving the band to size.

Socket Tightening

Chapman Double Ball Bearing Co. —After the shells are filled they are ready for receiving the sockets, and for this purpose a specially designed ball-bearing driver and a large single-ended tap wrench is used. The plug, or driver, consists of a squared shank, and a straight, threaded portion, of the same diameter and pitch as the inside threaded part of the sockets. Upon the upper part of the thread are two steel nuts fitted with grooves on their adjacent sides to form a ball-bearing raceway. The bottom nut seats against the socket, and is jammed by the upper nut on account of the much greater friction in the thread bearing than in the ball bearing. For the same reason the backing of the wrench instantly releases the plug from the socket from which it can be then unscrewed by hand.

Massey Harris Co.—The use of a drill press instead of a hand wrench for driving home the brass socket in the nose of shrapnel shells effects a double saving in the fact that a workman can maintain a higher rate of output; and secondly, the tool employed can be used to reduce the amount of work necessary on subsequent operations. In this case the shell is held in a hinged vise bolted to the table of an ordinary vertical drill press. A hollow mill is fitted to the spindle and when fed down on top of the socket, inserted teeth dig into the metal and take hold firmly. Continued pressure on the feed lever screws the socket home, the point of tightening being indicated by the teeth beginning to cut the edge of the socket. The cutter teeth are so designed that they do the work of a roughing tool, for machining the outside edge of the socket.

Socket Removing

Brown Boggs Co.—It is often necessary to remove the fuse socket, after the final weight test, in order to insert shot and bring the shell up to the desired weight. To remove the socket after it is finished requires careful handling, but the difficulty has been overcome by the

use of the following tool. It consists of a plug threaded right hand to fit the fuse socket. The shank of this plug is threaded left-handed and a nut made to fit. To remove the shell, the plug is first screwed into the socket and then the left handed nut screwed down until it comes in contact with the nose of the socket. Continued pressure causes the socket, plug and nut to unscrew as a unit.

Painting Devices

Vickers, Ltd.—In the painting of shells an ordinary air motor is being used for revolving the jig. Four plates are placed on top of cylindrical pieces secured to the top of the bench. These plates have a stem or shaft passing down through the bench. Attached to the bottom of each shaft is a gear which meshes with intermediate gears. To the central gear is attached the air motor shaft which is supported in an upright position. The shells are placed on top of the revolving plates and are driven by means of a square lug engaging with the square hole in the shell plug.

General.—The following device is giving good results in several shops, although the output is not as large as with multiple painting machines. A cast iron base is secured to the bench and has a ball groove machined on top. A hole is drilled through the centre of the base, and a shaft which is made to fit, is fastened into a head. A ball groove of the same dimensions as that in the base is machined on the bottom of the head, and a cup-shaped recess, with a square boss projecting upwards, is formed on top. Balls of suitable size are placed in the ball-race. The shell is placed in the head, nose down so that the square boss engages with the hole in the plug. The device is revolved by means of a grooved pulley placed on the shaft, beneath the bench, and driven from any convenient source of power.

Pump Drive

Canadian Westinghouse Co.—A simple and effective method of producing a continuous flow of cutting compound used in turning shell forgings includes the use of the back gear hub. The lathe spindle is direct driven by the belt at a constant speed, leaving the remaining steps of the cone unused, and the back gears idle. One of the cone steps not in use is cross belted to the back gear hub from which another belt drives a small centrifugal pump located at the bottom of the machine. By this method the supply of compound can be varied by belting from a larger or smaller step of the cone.

Special Chucks

Brown-Boggs Co. — The following chuck was designed to be used in connection with a Jones & Lamson lathe for rough turning nose and boring operations. The body of the chuck is flanged and bolted to the face plate. Fitted to the tapered bore of the body are three collet jaws, which are held together by means of two coil springs. A rod extends through the lathe spindle and to its inner end is attached a grooved casting which engages with a square lug on each of the three jaws. The outer end of the rod is threaded and carries a hand wheel. By this arrangement the jaws are drawn in, the tapered faces causing them to compress, and securely hold the inserted shell.

C. P. R. Angus Shops. — A simple chuck used in boring operations on shrapnel shells consists of a casting fitted to the lathe spindle. This casting is bored out to receive the shell after which it is split to a suitable distance back. Two studs are screwed into one-half of the casting and nuts on the other end of the studs cause the two sections of the split casting to close in, firmly gripping the shell.

Canadian Locomotive Co.—An excellent type of split collet chuck, for use in connection with a boring mill, is constructed with a heavy flange by which it is bolted to the table. The upright portion of the casting is bored to a sufficient depth, this bore being tapered at the mouth for a considerable distance back. A split sleeve, which is bored to suit the shell forgings, is turned to correspond with the tapered hole in the main casting. The bottom end of the sleeve is turned down, and threaded to suit a heavy nut, and passes down through the base. A recess is provided in the base of the casting in which this nut operates. When the nut is tightened against the top of the recess, it acts similarly to a jack-screw, the tendency being to pull down the sleeve, causing it to contract by the action of the two tapered faces.

C. P. R. Angus Shops.—For holding shells while grooving and waving, the following simple chuck is being used, and is giving satisfaction. The body is fitted to the spindle nose, and is bored out to fit a tapered split sleeve which holds the shell. The outside diameter of the chuck body is threaded at the end and a large nut fitted to it; the latter being recessed and threaded for slightly less than its entire length and the remainder bored to permit the shell to be slipped through. The shoulder which is thus left in the nuts bears against the outside face of the sleeve, and continued pressure on the nut forces the sleeve in, causing it to contract on the shell body.

General.—The chuck here described is one which has been designed for use in finishing the brass sockets. Fitted to the lathe spindle nose is a cylindrical casting, bored to a suitable size and depth, the mouth of which is tapered for a considerable distance back. A tapered split sleeve which is bored slightly larger than the shell is made to fit the bore in the casting or chuck body. The sleeve is compressed, when it is forced in, by means of a geared nut fitted to a threaded recess in the wall of the body, and which engages with a slot cut on the outside of the jaws. The nut is turned by means of a key and pinion, the teeth of which mesh with the teeth cut on the outside of the nut.

TORONTO WORKS DEPARTMENT EXPENDITURE

THE annual report of Toronto Works Commissioner indicates that municipal expenditure in public works has shared in the wave of retrenchment due to the necessity for economy in all non-productive investments. A decrease of \$1,342,757 is shown in the expenditure of the department up to December 4 over that of last year. The principal item of reduction is in the sewer section, the decrease being \$1,239,830.

The main sewage disposal works are now handling an increased flow, exceeding last year's flow by 4,000,000 gallons per day. New sewers to the extent of 32.4 miles were laid.

Roadways, including pavements and sidewalks show a decrease of \$801,039, leaving this year's figure of \$2,736,963 as the largest sectional expenditure. The mileage of pavement laid amounts to 32.867, against 42.93 last year.

The largest item of increase shown is that of \$591,233 in the railways and bridges section. About 25 per cent. of the steel required for the Don and Rosedale sections of Bloor Street viaduct has been fabricated, and 54,000 cubic yards of fill have been deposited in the Bloor Street section. Various other works, including two subways and two bridges, were completed.

The civic railway continues to show a steady increase, the St. Clair and eastern divisions amounting to 16 per cent. over 1914.

The contract for the filtration plant is completed to the extent of 70 per cent., and is expected to be in operation about June 1st.

The installation of two new steam pumping units of 24,000,000 gallons' capacity each has been completed, and now await connection with the distribution system, and contracts have been placed for two electrically-driven centrifugal pumps of 20,000,000 gallons' capacity each. The water consumption to November 30th, 1915, was 16,166 million gallons, compared with 16,818 million gallons for the corresponding period of 1914.

The Origin of Shell Sizes: Their Variety and Purpose

By C. T. D.

The superiority of Germany's ammunition supply was made doubly valuable by the uniformity of her artillery equipment. The overlapping of gun sizes in the Allied forces made the provision of numerous sizes of shells necessary, thus aggravating the problem of quantity supply. The elimination of odd-size artillery will proceed as rapidly as consistent with present operations, the adoption of standard sizes being a question still very much in the future.

WITH each increase of size in the projectiles made by the numerous firms in this country, there has been corresponding interest in the guns in which they will be used. The variety of sizes or calibres called for has not been so great as in other countries, but the comparatively small difference in size, for instance 4.5 in. and 4.7 in., has frequently given rise to inquiry as to the why and wherefore.

With the preparations for large shells going on actively in our midst, interest naturally centres on them more than on shrapnel, especially as the use of the latter seems to be postponed till such time as the enemy can be gotten out of his burrows.

Classification of Shells

For comparative purposes, shells are conveniently classified as heavy, medium and light, and a list of the more familiar British sizes with such particulars as are available is given.

The 9.2 in. shell is the largest so far in course of production by Canadian makers. This size of gun was adopted by England after a number of 9 in. guns had been supplied to Italy by Armstrong of Genoa. The size (9.2) was decided on owing to the adoption of 9.45 in., or 240 mm. as a general standard in most countries outside of England, Russia, Japan, and United States. Projectiles for this gun weigh 375 to 474 lbs., and firing charges 103 to 129, the Krupp standard being 419 lbs. for the shell, and 113 to 173 lbs. for the charge.

The 9.2 in. shells will continue to be in demand by Britain, although the disadvantages of non-interchangeability with the French 9.4 in. ammunition are bound to be felt on frequent occasions at present.

Numerous Shrapnel Sizes

A point which has been noticed by anyone taking even a casual interest in munitions is the number of sizes around 3 in. The sizes in use by the various nations include the French 75 mm. (2.95 in), the English and American 3 in. gun, equal to 76.2 mm., also a German gun of 77 mm.: the size most in use at the present moment being the 85 mm. (3.31 in.), which is in use by both French and German armies, and which is represented in the British sizes by the familiar 3.29 in.

The close approximation of these sizes has lead to the adoption of 3.3 in. as the standard shrapnel size, excepting the French 75 mm. (2.95 in), which possesses individual features of sufficient merit to insure its continued existence as a standard size by itself. As a matter of fact, the excellent qualities of this gun as a field piece, particularly its flat trajectory, render its adoption for short range trench work difficult; consequently in order to get full use of the enormous quantities of ammunition which are being made for this gun, the Creusot people are producing trench mortars which fire the shell at a high angle with a greatly reduced charge, thus enabling shells to be dropped into a nearby trench.

While 3.3 in. has also been in demand as a size for high explosives, there seems to be a probability that this class of shell will be produced more prolifically in the larger sizes of the light shells, and the smaller sizes of the medium shells.

The most important of the remaining sizes in the light group is the 4.7 in. which appeared as the French and German 120 mm. (4.72 in), and has become a standard size with all the leading powers. This size has been developed for naval and field work, and must not be confused with the 4.5 in. which seems to be used chiefly for howitzer work.

Popularity of 6 In. Gun

The 6 in. gun in British and American practice has its equivalent in the 150 mm. (5.9 in.) French and German size.

Shells of this calibre are perhaps more attractive than any other size from the producers point of view. In regard to design they are the largest member of the open mouth, closed base type, of which the 3.3 in. high explosive was the earliest prototype. The nature of machining operations, tooling equipment, etc. is very similar to the smaller sizes, also their features of being easily produced with unskilled labor. Shops, therefore, which were originally equipped for this size should be sure of a continuance of demand over some of the other sizes which are due to be discarded either during or after the war, and therefore will be supplied with ammunition on much more restricted lines than guns of a more permanent type.

The 8 in. and 9.2 in. which are the largest shells contracted for in this country are for use with howitzers on comparatively short range work, and should not be confused with naval or armor-piercing shells of similar sizes.

The 12 in. gun superseded the 10 in. so quickly and completely in British naval practice that Germany and Austria were at a disadvantage with their 280 mm. (11.02 in.) size commonly referred to as 11 in. These were developed by the Krupp people and copied by the Skodawerke establishment in Austria. They were of little use against the straight 12 in. gun, which for many years remained the standard maximum calibre for ships of the pre-dreadnought class.

	Light				Medium				Heavy		
Diameter in inches	3	3.29	4	4.5	4.7	6	8	9.2	12	14	15
Weight of shell, lbs.	.	....	29 to 35	3.5	43 to 62	90 to 115	200	290	772 to 981		about 1700
Weight of charge, lbs.	.	....	..	....	13 to 22	24 to 35			213 to 357		456 to 694

A Famous Gun

The 15 in. calibre is the most famous of large naval guns, and while present developments may see it further advanced in size, the splendid work done by this gun will insure it a safe place in the records of naval warfare.

The maximum size of artillery actually used in the war so far is understood to be the 420 mm. (16.5 in.) howitzer by Krupps, and the 405 mm. (16. in.) howitzer by Skodd. Very little has been allowed to become known regarding these howitzers or their projectiles, although investigations show that two copper driving bands, and a forward land or contact band of the same material are employed.

Fixed and Loose Ammunition

Ordnance of 3 in. bore and under is generally chambered to receive ammunition in which the propellant or driving charge is contained in a brass cartridge

case the exact quantity of the charge being fixed, hence the term "fixed ammunition."

Guns from 3 in. to 6 in. bore may be similarly constructed or may be designed for the use of loose charges in bags or cases, the amount of charge being proportioned to the desired angle and range of fire under various circumstances. Guns larger than 6 in. are nearly always fired with loose ammunition.

Quick-firing guns of 6, 3, and 1 pdr. sizes are in use by most nations, and receive their ammunition from various national arsenals. They are largely used in trench work and submarine attacks, and have been mounted on aircraft. Anti-aircraft guns have been developed in great numbers by all of the powers, but considerable reticence has been shown regarding their details.

Just what sizes of guns will survive can not be foretold in view of probable developments, but the ultimate elimination of many sizes which overlap or possess no justifying advantage, is certain. The present struggle has shown the vital importance, not only of having ample supplies for all guns, but the inestimable advantage of the fewest possible sizes, and these the most adaptable to varying conditions of the conflict. The question of interchangeability between different nations depends on factors which cannot be considered from a technical point alone, and will be determined largely by the political aspect of the world's affairs after the war.

LOCOMOTIVES FOR RUSSIAN GOVERNMENT

THE Canadian Locomotive Co., Kingston, Ont., are building fifty Decapod type locomotives for the Russian Imperial Railways, and the first lot of these has already been shipped. These engines are of interest, not only because of their design, which is a combination of Russian and American practice, but because of their being the first locomotives exported from Canada.

5-Ft. Gauge Track

The locomotives are designed for operation on a 5-ft. gauge track, which is generally used as the standard gauge by Russian railways. The axle loads are limited to 35,000 lbs. per axle, yet the engines are of considerable capacity, having a tractive effort of 51,500 lbs. at 85 per cent. boiler pressure. They are designed to haul 1,000 metric tons up a grade of .8 per cent. at a speed of about 10 miles per hour.

Special materials and equipment have been used to a great extent, and the construction is in accordance with the best American practice, many of the details being interchangeable with locomotives of the same type and size already built by the Baldwin and the American Locomotive Companies.

Fuel and Firebox

The fuel in service is a low grade of soft coal and is burned on a rocking four-section grate with two dump bars. The firebox is of the wide type, extending out and over the driving wheels, and is equipped with a security brick arch supported on water tubes. The boiler is of the straight type with a mud ring made up with cast steel ends and forged steel sides welded together. An auxiliary safety valve dome is provided which carries two safety valves and the whistle; this auxiliary dome is also used for inspection purposes. A third safety valve is attached to the cover of the main steam dome.

The firebox is of copper, as also are the staybolts in the water-legs. The front end of the firebox is supported by three rows of expansion stays; the nut on the upper end of the radial stays is seated in a die forged stirrup which is screwed into the roof-sheet. The locomotives are equipped with Schmidt superheater and outside steam pipes; superheaters have twenty-eight elements with a superheater surface of 563 sq. ft.

Forty-nine of these engines are equipped with the "Rushton" power screw reverse gear, while the "Casey-Cavin" screw reverse gear is to be applied to the remaining one, both gears being operated by air.

The machinery, frames and cylinders are designed after American practice. The pistons are of solid rolled steel with three cast iron packing rings sprung in, and are supported by an extension on the piston rod with a guide attached to the front cylinder head. The cylinder heads are of cast steel, single bar guides of I section being used. The main driving wheels have plain tires, while all the others are flanged, and the wheel base is such that the engine will traverse a curve of 350-ft. radius.

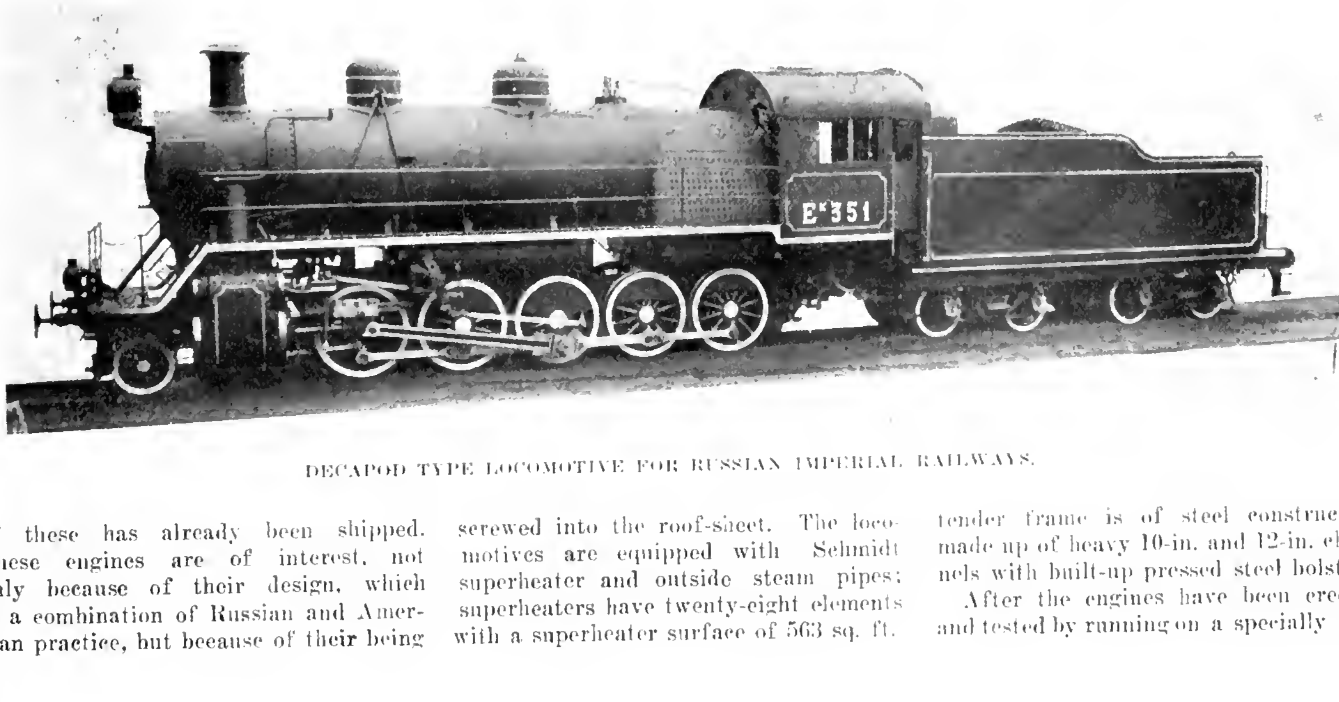
There is a wide running board of steel plate, diamond tread, having a handrail at the edges and continuing around the front deck plate in accordance with Russian railway practice.

The cab is of steel with side doors, and the front end of the tender is enclosed with a hood projecting under the cab of engine, protecting the crew from the weather. The couplers are of the hook and screw type of European practice, as are also the spring buffers. Russian-Westinghouse automatic air brakes are used, along with the special design of American Brake Co. foundation brake. A plug-type by-pass valve is fitted to the cylinder and is operated by a cam attached to the throttle lever, which in turn opens a globe valve allowing steam to pass to a small cylinder closing the by-pass. When steam is shut off, a tension spring opens the by-pass.

Tender

The tender is carried on two four-wheeled trucks of the arch-bar type with solid rolled steel wheels, the bearing and boxes being of the M. C. B. type. The tender frame is of steel construction made up of heavy 10-in. and 12-in. channels with built-up pressed steel bolsters.

After the engines have been erected and tested by running on a specially pre-



DECAPOD TYPE LOCOMOTIVE FOR RUSSIAN IMPERIAL RAILWAYS.

pared track by the builders, the locomotives and tenders are dismantled, crated and packed for shipment to Vladivostock, Russia. The principal dimensions of the locomotives and tenders are as follows:

General Data

Gauge, 5 ft.
Service, Freight.
Fuel, soft coal.
Tractive effort, 51,500 lbs.
Weight in working order, 192,000 lbs.
Weight on drivers, 172,000 lbs.
Weight of engine and tender in working order, 220,000 lbs.
Wheel base, driving, 18 ft. 8 in.
Wheel base, total, 27 ft. 10 in.
Wheel base, engine and tender, 60 ft. 1 in.

Ratios

Weight on drivers: Tractive effort, 3.34.
Total weight: Tractive effort, 3.73.
Tractive effort × diam. of drivers : equivalent heating surface, 780.
Equivalent heating surface : grate area, 53.4.

Cylinders

Type, Simple.
Diameter and stroke, 25 in. by 28 in.

Valves

Type, Piston.
Diameter, 12 in.

Wheels

Driving, diameter over tires, 52 in.
Driving journals, main, diameter and length, 10½ in. by 12 in.
Driving journals, others, diameter and length, 8½ in. by 12 in.

Boiler

Style, Straight.
Working pressure, 180 lb. per sq. inch.
Outside diameter of first ring, 70 in.
Firebox, length and width, 108⅛ in. by 86 in.
Tubes, number and outside diameter, 195 2-in.
Flues, number and outside diameter, 28 5⅜-in.
Tubes and flues, length, 17 ft.
Heating surface, tubes and flues, 2,393 sq. ft.
Heating surface, firebox (including arch tubes), 208 sq. ft.
Heating surface, total, 2,601 sq. ft.
Superheater heating surface, 563 sq. ft.
Equivalent heating surface, 3,446 sq. ft. Equivalent heating surface equals total evaporative heating surface plus 1.5 times the superheat surface.
Grate area, 64.5 sq. ft.

Tank, water bottom.
Frame, channel.
Wheels, diameter, 36 in.
Journals, diameter and length, 5⅛ in. by 10 in.
Water capacity, 7,400 gal.
Coal capacity, 8 metric tons.

OIL ENGINED COAL CARRIERS FOR GREAT LAKES

THE experiment which is about to be made on the Great Lakes with auxiliary oil-engined colliers will be watched, says Syren and Shipping, with interest by shipowners in the ocean trade. Since the outbreak of war the same idea has been given a new lease of life by owners on the British side of the Atlantic who have acquired a good many ocean-going windjammers and are fitting them with auxiliary engines. In the exceptional circumstances of the moment there is no doubt that the enterprises will be profitable — very profitable indeed — although it is doubtful if, when the conditions become normal, auxiliary ships will be able to live in competition with the large full-powered vessels which will be available.

At first sight the Great Lake experiments seem to have been induced by a sudden discovery of the hot-bulb engine's possibilities. As a matter of fact, however, through the withdrawal of steamers for ocean service much the same shipping position has been created on North America's great inland sea as exists elsewhere in the world. There is a shortage of tonnage, and in the circumstances the ordinary economic law which rules is inoperative.

What that economical law embodies is excellently illustrated by the New York paper which booms the new departure. "The old-fashioned 1,600-ton steamer went," it says, "to the scrap-heap long ago, for it could not carry enough, and discharging by primitive means was expensive. Bigger steamers, equipped with powerful steam winches, were built, and then bigger steamers yet with self-trimming devices, the latest of these carrying anywhere from 5,000 to 10,000 tons deadweight."

In view of that the average man will find it difficult to regard the future of auxiliaries "able to carry 4,000 to 5,000 tons" as rosy. Still, this is obviously a different problem from that which is in process of solution on Britain's side of the water. Schooner-rigged auxiliary vessels of this carrying capacity may cut into a good deal of the Great Lakes coal trade, and the type lends itself, especially in American hands, to very economical working. On this account shipowners will, we think, find a great deal in the experiments to interest them.

SHELLS FROM AUSTRALIA

ACCORDING to a report received through the High Commissioner for Australia, substantial progress is being made by manufacturers with the preparations for shell-making. High-explosive shells will, it is very probable, be turned out in Australia very soon, and shipments to Europe are expected to commence about the end of 1915. Further orders have, it is understood, been placed abroad for machinery, and the aggregate of the Australian orders to date will, according to good authority, fall little short of one million dollars. Other manufacturers are busy making lathes in their own workshops, but these will not be of the automatic type, and will require skilled labor.

The conditions laid down by the Federal Government fix the period of delivery as expiring on March 31, 1916. Manufacturers are taking exception to that limitation, it being claimed that the shells made prior to that date would not be sufficient to enable the initial expenses to be spread over a period long enough to leave any margin. Some machine-shop owners, who have contemplated laying out a considerable sum in new machinery, have deferred doing so pending an extension of this date, or some other basis being arrived at. One suggestion put forth is that, as the Imperial Government has notified its desire for as many shells as possible, manufacturers should be instructed to go ahead, on the understanding that the Government will give three months' notice when no more shells are required. The manufacture of gauges is now well in hand.

CANADIAN PULP AND PAPER EXPORT

THE high levels of Canadian pulp and paper exports continue to be well maintained, according to the latest export figures, which are for the month of September. While there is a contraction from the previous high marks, the falling off is so slight as to make no pronounced impression on the general growth of the business.

With a total of $1,207,460 for the month, newsprint exports aggregate $7,870,749 for the first six months of the current fiscal year. A year ago, for the same period, the total was $6,569,199, or $1,301,750 less than this year.

Newsprint trade with the United States, which, of course, is Canada's latest customer, totalled $1,099,369 for September, bringing the half year's total to $7,008,987, compared with $5,772,911 for the same period last year. To a very large extent this is a reflection of the better times the United States is enjoying, prosperity that finds expression in greater advertising of all kinds in the newspapers.

England and the colonies are increasing their trade with Canada. England's buying of our newsprint in six months this year totals $106,761, compared with $101,290. Australia's trade aggregates $306,143, compared with $298,576. New Zealand's imports are slightly down, be-

ing $149,661, as against in 1914, $154,810.

Canadian pulp mills benefited early in the present year from the strike in Northern York mills: in August the buying of Canadian chemical and mechanical pulp reached unprecedented proportions. There was slightly less demand for the Canadian product in September, however.

THIS WINTER'S LUMBER CUT

IT is stated that the lumber cut this winter will be at least fifty per cent. less than last year on account of a shortage in bottoms to carry the stuff from the New Brunswick ports, and also because the quantity carried over from last year is very much in excess of preceding winters. The price is a good deal higher for lumber, but steamers are so scarce on account of the war that the few chartered up to the present time indicate that the freight will be higher than the money received for the cargo itself. The demand in the United States for New Brunswick lumber has increased considerably, but here also the lack of vessels will interfere with the transportation.

It is believed that if the war were to stop suddenly, thus freeing a great many steamers now engaged in the transportation of troops and supplies, there would be a very considerable boom in the lumber trade of New Brunswick. Lumber will be in great demand in Europe, rebuilding what has been destroyed during the conflict.

MACHINERY MARKET IN CHINA

THE following particulars regarding methods of securing electrical and other machinery contracts in China have been furnished by T. M. Ainscough, the special commissioner appointed by the Board of Trade to inquire into the conditions and prospects of British trade in China:—

There would appear to be two clearly defined systems by which the large contracts in China, both Government and private, for the supply of plant and machinery can be secured. The first is that of appointing one of the large mercantile houses, having branches at all the important centres, as general agents on a fixed agreement for a term of years, and is the system employed by almost all the large German manufacturers of arms and munitions, industrial machinery, and electrical machinery and supplies.

Its principal advantage is that the manufacturer enjoys all the benefits accruing from the connections of an old-established firm ready to hand, offices in all the principal treaty ports, and valuable Chinese connections, in return for a fixed percentage of rebate on his prices to cover agency commission and expenses. In addition it would be advisable to send (say) four or five qualified engineers trained in the home works, preferably with some knowledge of Chinese, who would be attached to the principal centres in China, use the offices and staff of the agents and visit all provincial capitals, arsenals, mints, and other places where the demand for machinery warrants their attention. Unfortunately, at present, there are few British or colonial mercantile firms possessing a widespread organization embracing branches in all the principal treaty ports.

The other system is to conduct business direct with the Chinese, and open offices at four or five of the main centres, with qualified engineers attached, who are competent not only to draw up specifications and quotations on the spot, but to carry on with the help of a good Chinese staff lengthy negotiations with Chinese officials and native purchasers. It is a well-known fact in China that there is very little money to be made in laying down large electrical installations in that country. Most of the profit is derived from the supplies and accessories, and consequently German and American firms always endeavor to stipulate in the contract that renewals and supplies shall be purchased through the firm supplying the original installation.

United Kingdom makers have, as a rule, employed agents in one or two of the ports, but have not carried on a campaign all over China as large German firms have done. German firms have always worked with an eye to the future, and in cases where a plant was invaluable as an advertisement to Chinese and others, they were prepared to quote it at a loss to secure the contract. Examples of this may be found in the work executed for the municipal power station at Shanghai, the Shanghai native city tramways, and the Wuchang electrical installation.

INTERCOLONIAL RAILWAY BETTERMENT

ABOUT 10,000 tons of new steel have been laid during the year on the main system of the Intercolonial: about 20 per cent. of the main line is now laid with 85-pound steel, and this will be continued gradually until the whole of the main system is thoroughly modernized. During past administrations the last thing thought of was the condition of the roadbed, all the energy being used up in the maintaining of the system as a great political machine.

The bridges on the Intercolonial between Halifax and Montreal are now strong enough for the heaviest traffic. There was a new subway carried out in Moncton under Main street; new equipment was ordered, though this did not run up on to the millions, as was originally intended. The Intercolonial, however, is now a modern line giving a keen schedule and asking no favors, even if it is a government road, but soliciting business in competition with the other roads, and insisting that it is able to give an equal, if not a superior, service.

MONTREAL TRAMWAYS CO. IMPROVE AND EXTEND SYSTEM

IMPROVEMENTS in track construction and rearrangement of curves at congested corners have formed a considerable portion of the year's activities of the Montreal Tramway Co. According to general manager Hutchison, the sum of $500,000 had been spent from April 1st to October 31st in track laying alone.

A feature of this work has been the laying of tile pipes between the tracks for the purpose of carrying off water and preventing damage by frost. This work has been going on for some time till every foot of standard roadbed is now drained by porous French tile. The method of construction adopted is to lay broken stone, about one and a half inches in diameter, to a depth of eight to ten inches below the ties between which concrete is filled in, forming an elastic roadbed. The French tile which is six inches in diameter, is laid between each rail, carrying off the water and preventing the bulging of tracks when spring time comes.

The company's experience has shown this construction to be practically perfect, the only disturbances showing at complicated intersections.

Every congested intersection is now being perfected by the provision of more clearance on the curves, whereby 75 per cent. more cars can be handled than was formerly the case. Previously, cars could not pass on regular corner curves and the recent work has greatly facilitated handling of the traffic.

A considerable amount of work was done during the year on Notre Dame Street east, a double track now being extended as far as Pointe aux Trembles, which is only about four miles from Bout de l'Isle, although the old Terminal line is still being used from La Salle Ave. to the end of the island. It is understood, however, that the double track now stopping at Pointe aux Trembles, will be extended sooner or later right down to Bout de l'Isle, thus obviating the necessity of keeping the Terminal open, and, in fact, it is understood that the right of way now being utilized by the Tramway alongside the C.N.R. will one day belong permanently to the last named company's right of way.

Review of the Past Year's Steel, Iron and Metal Markets

Staff Article

Prosperity is rampant so far as the production of steel and iron is concerned, and, only in some lesser degree does a like condition exist relative to the more prominent metals. Prices of all may be said to have pyramided to extreme heights, and, while in a number of instances some recession has taken place, it will be found that the upward trend continues general.

IRON AND STEEL

THE conditions prevailing in the iron and steel trade at the close of the year 1915 are the most extraordinary that have ever been experienced in the history of the trade in Canada. At the beginning of the year business was dull, and only the most optimistic expected any great improvement, the basis for the latter being the possibility of increased export business to markets hitherto largely supplied from Germany. A hope was generally expressed that Canadian steel companies might be able, by means of a great effort, to capture some of the foreign business likely to develop as a result of the war. As events turned out, the business came to Canada, but in a rather different form than was anticipated. There still remains, however, the possibility of hopes being realized, and Canadian steel companies may be successful in the open market for such products as they can manufacture when the war is over.

Munition Demand the Main Factor

The cause of the present unparalleled prosperity in the steel trade is, of course, the enormous demand for munitions. It was not, however, until about the middle of July that the advance in prices of raw and semi-finished materials began, although for some months previously a large number of shells had been made and the output of steel had been increasing. The mills at the beginning of the year were quiet, and were thus in a position to handle a considerable tonnage without much difficulty, and by installing forging presses were able to meet the demand for shells for some time. Eventually the need for munitions became so urgent that the mills were soon operating at capacity, and have since been obliged to make large extensions to their plants. During the first half of the year business was gradually working up to a normal condition. After that, with the heavy increase in demand for munitions, came the extraordinary activity in the trade which still exists. The need for steel has become so great that Canadian mills cannot supply the demand, and a considerable tonnage has been imported from the States.

Steel Famine Possible

With a shortage of steel, it was obvious that prices would advance, and since July the market has been gradually rising, until prices have reached a level never before attained in this country. The close affinity between this market and that of the States has been clearly demonstrated during the year, and higher prices at Pittsburg have at all times been followed by an equivalent advance here. About the middle of November there was an important development in the steel trade, when the United States Steel Corporation withdrew prices on steel bars for Canadian consumption. This action was taken on account of the inability of the mills to fill orders or make any definite promise of delivery. Existing contracts were filled, but no new business was solicited. For some time previous to this, the mills in the States had been booked up with orders for tonnage from Europe, and had been rapidly getting behind on deliveries.

Activity in Futures

At the present time orders are being taken for delivery into the second half of 1916, and this activity in futures is almost entirely owing to the heavy demand for munitions. As long as present conditions prevail in the steel trade in the States there is practically no possibility of the Steel Corporation resuming their former connection in this market. The result of this may be serious, as it is estimated that Canada imports about half its steel requirements from the States, and with the demand increasing all the time, it follows that a serious shortage may develop. The rapid increase in prices of billets is another indication of the shortage of steel. In less than six months Bessemer and open-hearth billets have advanced about $10 per ton, while forging billets have doubled in price.

High Prices General

The effect of the high price and scarcity of steel has been widespread, and the natural result has been an increase in cost of finished steel products covering a wide range. Sheets and wrought iron pipe are two lines which have been affected, and have been gradually advancing for some months. All lines of bolts, nuts and rivets have advanced, while higher prices for boiler tubes and boiler plates have been recorded on more than one occasion. In fact, all steel products have advanced, and there is every indication that higher prices will yet prevail. Another feature which had an almost immediate effect on prices was the increase of 7½ per cent. in the tariff last March. The market had, however, become adjusted to the new conditions before the upward movement started in July, and the increased tariff was almost forgotten in the excitement which followed later.

Domestic Purpose Steel

The demand for steel for domestic requirements has been for the most part light, although there has been some improvement in this regard during the second half of the year. Factory and shop extensions have created some business in small shapes, but the building trade generally has been dull. The financial stringency during the entire year has seriously affected the building trade on account of high rates of interest charged on loans and the uncertainty as to future developments. A certain lack of confidence has been noticeable, more especially during the early part of the year, and the general contraction in ordinary business and decrease in values were not calculated to improve conditions in the building trade or develop interest in building propositions.

The difficulty of raising money has made it necessary for municipalities to exercise rigid economy on civic works. There has, therefore, been comparatively little cast iron or steel pipe laid down this year. Railways have reduced their maintenance expenditure to a minimum and track extensions have been very much curtailed. The demand for rails and other steel products used in railway construction and equipment has, therefore, been considerably less than in normal times. The steel companies have not felt the loss of this business this year as they did during 1914, as their plants have been turned over almost entirely to the production of steel for munitions. One steel plant, in addition to a large munition business, has rolled a large quantity of wire for military purposes.

Steel Plant Extensions

A feature of the present boom is the large extensions which practically all the steel companies have made to their plants. These extensions have cost large sums of money, for in addition to the buildings, open-hearth furnaces and rolling mills have been installed with all the necessary and costly equipment. The Dominion Steel Corporation, the Nova Scotia Steel & Coal Co., and the Steel Company of Canada have all incurred heavy expenditures in extending their plants to meet the enormous demand for steel for munitions. These concerns have also installed heavy type forging

presses for the production of shell cases. The Algoma Steel Co. was for some time very busy on rail orders, but latterly has also been engaged on the production of steel for shells. During the year an industry closely associated with the steel trade was established in Hamilton, Ont., for making galvanized sheets. The concern in question, the Dominion Sheet Metal Co., installed a plant for galvanizing sheets, the first plant of its kind to be operated in Canada.

Judging from appearances, there is every probability of the present era of prosperity being continued for several months yet. How long it will last depends entirely upon the duration of the war. It is reasonable to suppose that while the war lasts the steel trade will be active; what will happen after that is a matter of conjecture. It is to be hoped that the Canadian steel companies will be able to extend the scope of their business and participate in the large demand for steel products that it is generally believed will exist in Europe after the war and during the period of reconstruction. From a financial standpoint the steel companies have made large profits and are in a sound condition. This should go a long way towards helping them to extend their connections, and enable them to lay down plants for making products which have not heretofore been made in Canada.

METALS MARKET

THE metals market has during the entire year been very much influenced by war conditions. This is naturally what might have been expected, but it is doubtful whether at the beginning of 1915 any among those interested anticipated such fluctuations as developed in the succeeding months. The enormous demand for munitions alone eventually became far greater than was expected, and, therefore, a correspondingly heavy consumption of metals for their manufacture resulted. The metals particularly affected were copper, lead, antimony, and spelter. Copper and lead did not fluctuate to the same extent as the others mentioned, because production was increased to take care of the consumption, and there was never at any time any marked scarcity. Antimony at the beginning of the year was at a high level, but, as supplies became very scarce, the price advanced to more than double the figure prevailing in January. The spelter market has been very erratic, and speculation has on more

than one occasion driven prices upward. The usual recession followed, thus causing many and wide fluctuations.

As in the previous year the tin market has been erratic and a wide range of prices has been the logical result. Tin has been affected by the war, but not in the same sense as copper or antimony. The tin market was affected more by the possibility of supplies being unobtainable rather than any extraordinary demand. The aluminum market for some months was very steady, but about the middle of the year a scarcity of this metal began to be experienced. This has affected the market more and more, until the price at the end of the year has reached three times what it was at the beginning. The close of the year finds producers extremely active. Many old refining plants have been requisitioned and more modern plants have been extended to take care of the demand. In many cases old workings that ceased to pay are in operation.

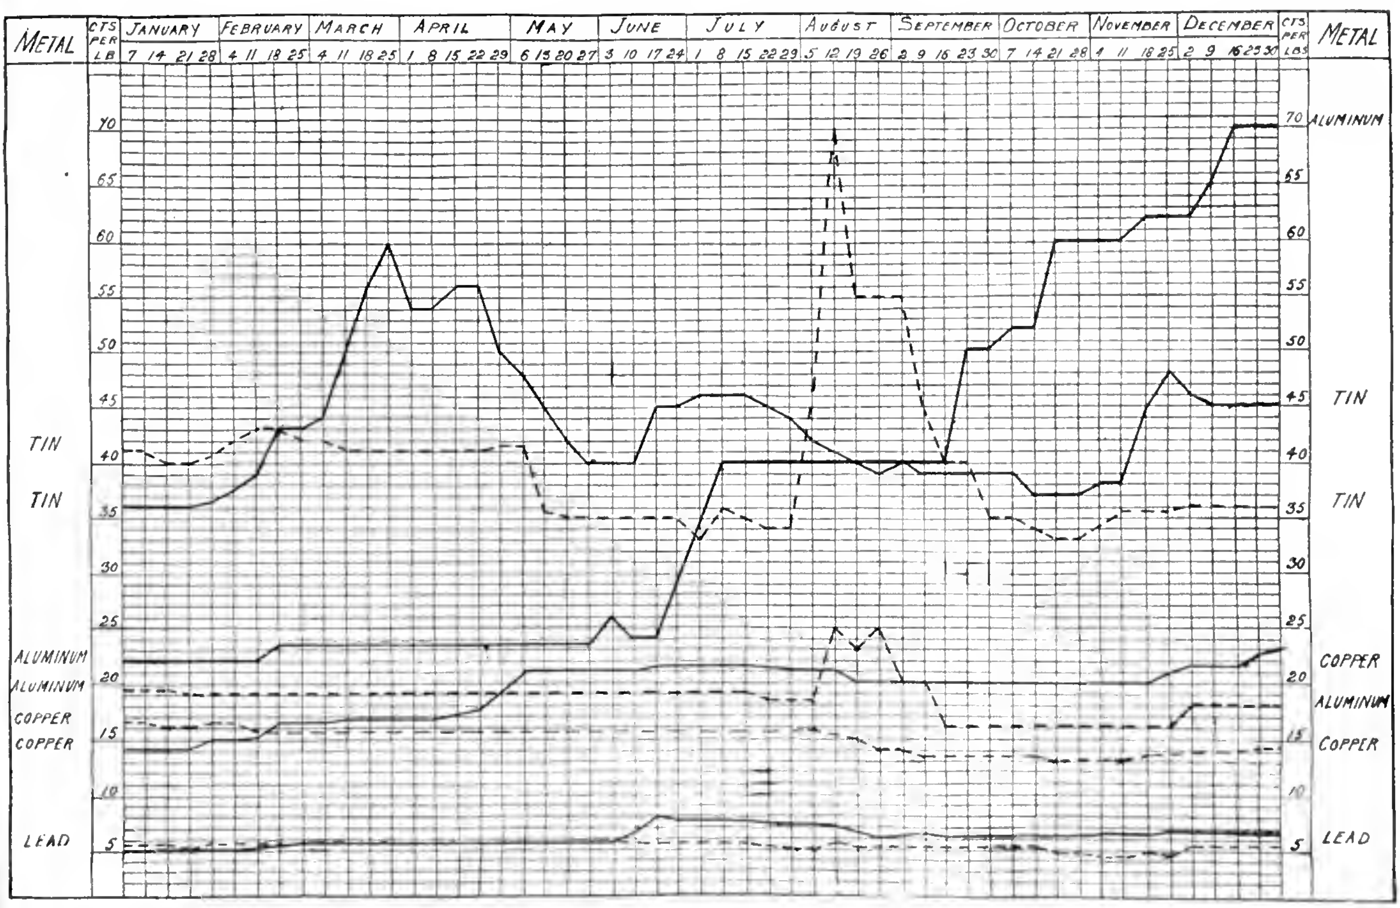
Tin

During the latter part of 1914 the tin market was affected by the loss of cargoes at sea, some ships being sunk by enemy cruisers. This year there has been no recurrence of these conditions, but the market has fluctuated considerably, especially about the end of March, when the highest level was reached. In the early part of the year the British Government placed an embargo on tin shipments, except under very stringent



PRICE FLUCTUATIONS OF TIN, ALUMINUM, COPPER AND LEAD DURING 1915. DOTTED LINES SHOW 1914 PRICES.

conditions. This at the time unsettled the market, especially in New York, as it had a tendency to delay shipments and also create uncertainty as to the obtaining of sufficient quantities. The market on this account was very firm for a while and prices high. The situation in time became considerably easier and the market steadier. The trade routes from the East have been open all the year, and shipments of tin have been coming forward regularly, until now stocks on hand are amply sufficient to meet the demand. Some excitement was caused about the end of November when an unfounded rumor to the effect that the Suez Canal had been closed caused a sharp advance, but the market soon weakened and prices dropped.

It must be admitted that there is a possibility of the canal being closed for military reasons, in which case shipments of tin would be delayed from three to four weeks coming round by the Cape. Such a contingency, however, would not seriously interfere with spot supplies, but would no doubt cause prices to jump up, especially if the market was at all nervous. Considering the conditions prevailing last January the market was not particularly high, and during the whole of that month was steady at 36c. During the month of February prices advanced to 43c, and by the end of March had jumped to 60c, the highest level of the year. The market at the time being largely speculative, and with no backing, prices soon began to decline and by the end of May tin was being quoted at 40c per pound. Towards the end of June the price again advanced to 45c, and in July to 46c. afterwards gradually falling to 39c. this level being practically maintained until early in October, when it fell again to 37c. During November the Suez Canal scare caused another sharp advance to 48c which was followed by a steady decline. finishing the year at 45c.

Copper

Copper, being one of the most important metals used in the manufacture of munitions, has naturally attracted considerable attention during the year. The market has. considering the conditions prevailing, been remarkably steady, registering a range of only seven points for the entire year. As the year progressed. the consumption increased until eventually all records were broken and production reached the highest point ever. The position of copper has been a particularly strong one throughout the year, and there is no doubt but that it will be maintained while the war lasts. The copper situation was for a time unsettled, as being a contraband of war. supplies which had hitherto been going to Germany through neutral countries were eventually stopped by the British Government making certain arrangements with those countries. The market was in consequence affected, as several important shipments were held up pending decisions of the British Prize Court established for the purpose of dealing with contraband cargoes captured at sea. In time the situation was straightened out. and there has been little trouble recently from this source.

At the beginning of the year the price of copper was just over 14c. The market soon became stronger and the price advanced gradually. About the middle of April the price rose rapidly, and early in May, 20c was reached. Towards the end of June the market advanced to 20½c. and this level was maintained until the end of July, when it dropped back to 20c, and again about the middle of August to 19c. This level was maintained until the end of November when the market became stronger, and prices gradually advanced to 21½c which level was maintained until the end of the year. The market finished the year firm with every prospect of higher prices at the next buying movement. An interesting feature in the copper market during the year has been the decision of the Canadian Government to assist in the development of copper refineries in Canada. A special commission was appointed to investigate the possibilities of operating refineries on a commercial scale. Success in this direction will help in no small measure to lower the production cost. as hitherto practically all copper mined in Canada has had to be refined in the States.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Messrs. S. Ruperti and Alexsieff, care Military Attache, Russian Embassy, Washington, D.C.

Spelter

The market has been very unsettled for the greater part of the year, and has been influenced largely by speculation. There has been a very heavy demand for spelter for munitions but consumption fell off for ordinary uses. The high price of spelter has seriously affected several trades. particularly galvanized sheets, some makers having practically withdrawn from the market on this account. Outside of the United States. the principal sources of supply were Belgium and Germany. With no spelter coming from either of these countries, the demand centred on the States with the result that the mines there have been extremely active, and the industry has been booming. Zinc ore, a few months ago reached the unprecedented price of $100 per ton at Joplin, Mo., and later touched $110 per ton. A record such as this indicates to some extent the effect which the war has had on this industry. Notwithstanding the heavy consumption of spelter there has been nothing to warrant the sharp fluctuations that have taken place, the market having on more than one occasion run wild. The high price of primary spelter, the grade used in making cartridge cases, did not affect the general situation to such an extent as the high cost of the lower grades, the latter being used in industries where the cost of spelter is an important consideration.

The price at the beginning of the year under review was practically normal but it did not stay long at that level. At the end of January it began to advance. and by the end of March spelter was quoted at 15c. A sharp decline to 12c followed. and the market was steady until the end of April. when it strengthened and the price again advanced sharply, touching 30c in the middle of June. the highest level attained during the year. A sharp reaction occurred. and the price fell to 26c at the end of June. but the market recovered immediately. advancing to 28c, where it remained until the end of July. The market then suffered a sharp break and prices tumbled until the end of August when a 16c level was reached. The price jumped back to 19c during September. and then dropped one point to 18c, where it remained until the middle of November. At the beginning of December. the market was firm at 20c. and about the middle of the month advanced to 21c, which quotation was maintained until the close of the year.

Lead

An enormous quantity of lead has been consumed during the year largely in the manufacture of munitions. but with the exception of a sharp fluctuation in June, the market has been very steady. The position of this metal has been generally a strong one. As the consumption increased so did production, and conditions have been for some time fairly well balanced. The control of the market by the "Trust" in New York. has been an important factor in the stability of lead,

"Independent" quotations being usually pretty close to the "Trust" figures. The price of lead is now higher than the average for any year since 1907, but considering the conditions prevailing, this is only what might be expected. As will be gathered from the above there is nothing of particular imprtance to note with regard to price fluctuations. An advance from 5c to 6¾c during the greater part of the year with a sharp advance to 8c in June were the principal features.

Aluminium

The increasing utility of aluminium has been clearly demonstrated during the year just closing. The demand for this metal has been out of all proportion to the supply as it is being used to a large extent in the manufacture of war equipment. The aluminium produced in Great Britain is being entirely absorbed in that country. The output in the States is controlled by a "Trust" who also have properties in Canada, and the total aluminum production in the States and Canada for 1915, has been estimated at about 50,000 tons or nearly double that of 1914. At about the half-year a scarcity of aluminium developed which became more acute as the year progressed. The market consequently became very strong and prices have been more or less nominal

The average price of aluminum during 1914 was about 18½c per pound. At the beginning of 1915 the price was 22c, not particularly high considering that the war had been in progress about five months. The market was comparatively steady until early in June when it began to move and advanced about 2½c to 26c, reacting immediately to 24c. The real movement began about the end of that month when the price jumped to 40c, staying at that level until the middle of September. The scarcity of aluminium then became serious, it being practically impossible to get the metal. Prices consequently continued to advance rapidly until a range of 65c to 70c was reached about the middle of December which level has since been maintained.

Antimony

The position of antimony has of course been greatly affected by the war, as large quantities of it have also been used in the manufacture of munitions. In fact so great was the consumption of this metal that a scarcity developed early in the year, and prices naturally advanced to unprecedented levels. English antimony has been off the market for several months and the British Government early in the year assumed control of that market. This action was taken in order to secure and conserve the supply. Large quantities of antimony are being shipped from China and Japan, while in the States the industry has recently developed, and antimony is now being obtained from American ores.

A glance at the diagram will show clearly the big advance which antimony has made during 1915, the average price in normal times being about 8c to 9c per pound. At the beginning of this year antimony was quoted at 18c, a little better than the highest monthly average for 1914. The market began to move early in February, and climbed steadily to 25c at the end of April, jumping up to 40c in the middle of May. The market remained steady at this level until the middle of September when it weakened, the price dropping to 35c at the beginning of October. This level was maintained until the middle of November when the market became stronger and prices advanced to 42c in the latter part of the month. Since then the market has shown a weaker tendency but prices have been maintained at the above level.

CANADIAN PURCHASES FOR FRENCH WAR OFFICE

Philippe Roy, General Commissioner for Canada, Paris, advises the Department of Trade and Commerce, Ottawa, that an order has been issued by the War Department of the French Government to the effect that all purchases made by the Supply Branch in Canada will pass through the Hudson Bay Co. Canadian producers should therefore submit their future offers through the office of that company at Montreal. It is further stated in Mr. Roy's communication that Canadian lumber, steel and meat will find in France an important market for years to come, but it is necessary that Canadian firms should have in Paris representatives entrusted with the necessary authority, especially if it is desired to secure Government contracts.

HIGH-SPEED TOOL STEEL SITUATION

The situation in regard to high-speed tool steel has become acute and great difficulty is being experienced in obtaining supplies in sufficient quantities to satisfy immediate requirements. The two causes which have largely contributed to this situation are the scarcity of ferro-tungsten and the big consumption of tool steel. Ferro-tungsten gives to high-speed steel its peculiar characteristics and was formerly obtained in considerable quantities from Germany; this source of supply is now, of course, cut off. Tungsten is also obtained in important quantities from Burma and in a lesser degree from the United States, but owing to the peculiar conditions associated with the mining of tungsten, progress has been slow in increasing production to the extent necessary to keep pace with the consumption. The manufacture of tungsten powder has been developed in England during the present year, and has helped to some extent to relieve the situation. The demand for tungsten has increased at a greater rate than production, hence the scarcity.

During the first few months of the year supplies of high-speed tool steel were fairly easy to obtain, but eventually the demand increased to such an extent that a serious shortage developed. Owing to the enormous demand in Great Britain for tool steel for munition plants, the British Government practically prohibited the export of high-speed steel, thus cutting off to a large extent one source of supply. Stocks in Canada were soon depleted and prices advanced rapidly. In the States the demand also increased, as a large number of plants were engaged in making munitions. Steel makers in that country were thus unable to fill all orders from Canada as the domestic consumption was also increasing rapidly and taxing the capacity of the mills to the limit. The makers got behind on their orders and consumers had to be contented with what they could get regardless of price. The question of price did not, however, cut much of a figure as practically all the steel was required for munition plants.

As already stated, prices advanced rapidly. High-speed tool steel averaged about 60c per pound in the early stages of the war, but, as the demand developed, prices advanced, and to-day high-speed tool steel costs anywhere from $2.75 to $3.10 per pound. At the close of the year the situation is much the same as prevailed during the last quarter, although the shortage has probably become more acute. The makers of steel have meantime extended their plants, production has therefor increased considerably and will probably at no very distant date catch up with consumption. The probability is that the situation will gradually improve during the first half of 1916, as supply and demand will be more evenly balanced.

Safety First.—British Columbia paper and pulp mills will shortly introduce safety first schedules and devices. A committee has recently been investigating conditions in the Wisconsin mills with that object in view.

RECORD ORDER FOR COPPER

REPRESENTATIVES of the British Government on Dec. 22 signed a contract with United States copper producers for 135,000,000 pounds of metal, the largest single order ever placed in this country. The Anaconda Copper Mining Co., the American Smelting & Refining Co., and the Tennessee Copper Co. were the principal concerns to share in the order. The Anaconda, it is said, got the bulk of the contract.

The price was close to 21 cents a pound, the highest price paid in New York for more than five years. Payment for the order in full will amount to over $28,000,000 and the sellers will receive cash as the copper is delivered. The contract provides for delivery at the direction of the British Government, and the metal will be placed within the next year.

Usually contracts for round amounts of copper call for monthly deliveries, but the buyer in this case may ask for five million pounds next February, say, none in March, and fifteen million in April. Owing to this provision, it was understood the price was fractionally higher than current quotations for electrolytic copper, which ruled on the above date around 20½ cents per pound.

While no other item of business has approached this in the copper trade recently, buying has been heavy. It is estimated that total sales last week amounted to 200,000,000 pounds. The market is believed to be pretty well cleaned up, and it is thought that producers will enter the New Year under exceptionally favorable conditions.

MANITOBA MINERAL PRODUCTION

IT is estimated that the mineral production of the province of Manitoba for this year will exceed $2,500,000, this being based on the production for 1914 which was $2,428,908, and which in turn was a $200,000 increase over the 1913 mineral production.

The opening of the country in northern Manitoba by the Hudson Bay Railway will, it is expected, materially increase the mining development of the province, as there are believed to be rich gold deposits in the northern part of the province, that section of Manitoba having more mineral possibility of all kinds than the older settled districts.

Coal mining in Manitoba has not been carried on to any large extent, though there are known to be coal areas in the province of considerable worth. However, Manitoba coal has been in use in Winnipeg for some years, and the two and a half million mineral output for this year will be largely made up of coal.

Surveyors believe that there may be discovered silver deposits in Northern Manitoba which will in time prove to be valuable. The country in Northern Manitoba is not unlike the country in Northern Ontario and is similar in many respects to the Cobalt country. Gold in small quantities has been found in the sands surrounding the lakes in the northern part of the province.

Although the mining industry of Manitoba is the least developed of all Manitoba industries, the mines will have produced in three years including 1915, minerals to the value of $7,130,000. There has been a continual increase since 1912, but the development of the next year or two is expected to be very much larger in scale than heretofore.

PANAMA CANAL RE-OPENING OUTLOOK

THE U.S. War Department, Washington, D.C., have been advised by Major-General Goethals, governor of the canal zone, that he is still unable to make any prediction as to when the slides in the Gaillard Cut will be sufficiently removed to allow the world's shipping to pass through the Panama Canal. Several small vessels have been allowed to pass through, but these drew fifteen and one-half feet of water and less. The depth of water in the locks and in the channel of the canal is to be forty feet, when the slides are removed.

The fact that General Goethals is not able to say when the canal will be ready for use by larger vessels and commerce generally was announced by the Washington office of the Canal on December 21, after messages had been sent to General Goethals seeking the facts. When his reply was received, this announcement was issued:

"There have been several reports recently in the newspapers regarding the passage of vessels through the Panama Canal. A cablegram asking for information has been sent to the Isthmus and a reply has been received from which it would seem that a temporary opportunity to pass small craft drawing 15½ feet or less was taken advantage of, and certain vessels which had been held since the canal closed were allowed to pass the slide. If a similar opportunity offers a few additional vessels of greater draught, which have also been here since the closure of the canal, will probably be passed through, but the governor warns that conditions are very unstable, and it is impossible to estimate in advance what the probable available channel will be at any succeeding date."

Fort William, Ont.—From January 1 to November 30, 1915, the building permits issued and their total value, totalled 105 and $639,430 respectively.

1915 OUTPUT OF THE NOVA SCOTIA STEEL & COAL CO.

THE Nova Scotia Steel & Coal Company is believed to be the only concern in Canada which is producing munitions of war in their entirety. With the exception of the copper-driving band, all essential parts of shells from 15-pounders to 9.2-in. projectiles are made from raw material—iron ore, coke, and coal—recovered by the company on its various properties.

The output for the past year has not materially increased in point of tonnage, but has been enhanced considerably in value, due to the change in nature of most of the product. Pig iron, amounting to 72,803 short tons, was produced, while the tonnage of steel ingots made amounted to 97,000 short tons. Of the steel output, 60 per cent. was manufactured into munitions in the company's shops, 15 per cent. was exported, and 25 per cent. was sold for home consumption.

The success attained at the beginning of the year in the manufacture of forgings for 15-pdr. and 18-pdr. shrapnel shells induced the management to proceed with the manufacture of larger sizes, until at the present moment all sizes of shells up to 6 in. are being produced, and additional plant for the production of shells up to 9.2 in. dia. is being installed as quickly as possible.

These large shells, like the small ones, are manufactured complete, ready for export, and undertaking of this work has given employment to a greatly increased number of men.

The Eastern Car Co., a subsidiary concern, has been executing contracts for the Russian Government, including 2,000 box cars of special design and construction, having a capacity of 40 tons. At the beginning of this month 1,375 cars had been shipped to Vladivostock, and the balance was expected to be despatched before the end of the year.

A comparatively small amount of business was done in ore shipping during the past year, and that went entirely to the United Kingdom. The coal output has been much less than in recent years, due to shortage of labor caused by the enlistment of skilled miners, though even if the output had been up to the average of recent years, the abnormal cost of shipment by boat would have prevented it being shipped to the St. Lawrence at a profit.

Prospects for 1916 indicate that the iron and steel department will be fully employed, enough munition work having been booked to absorb the output of furnaces, mills and forges. A gratifying feature of the present activity is the number of men engaged. This is larger than at any previous time in the company's history, while the wages paid are also higher than ever before.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, Que., June 28, 1915. — It would appear that the tendency of the metal market is to become stronger and steadier. It is true that there have not been any sudden increases in prices; the increments being mostly fractional, but of a continuous order. The continued demand for certain alloys of the different metals entering into the manufacture of shells has been the cause of recent disturbances on account of stock shortages.

Up to the present there are numerous manufacturers who are just beginning to adapt their plants for the making of shells and there are sure to be others who will come in later. In fact, it appears that this business is only in its infancy. These considerations may carry some weight with the holders of metal stocks, and cause them to anticipate even higher prices. As far as the steel and iron trade is concerned, although the demand is light, there does not seem to be any apparent weakening in quotations.

Twisted Reinforcing Bars.

The extension to the Harbor Commissioners' elevator No. 2 will take care of an enormous quantity; tenders on this item being now under consideration. There is also a large reinforced concrete dam to be built on the upper stretches of the St. Maurice river above La Tuque,

P. Q., this dam to be used for storage purposes. The Commission of Streams for the Province of Quebec, it is said, have the plans for this work well in hand, and several thousand tons of reinforced bars will be required. No tenders have as yet been called.

Among the price movements of the past week, that of aluminum is most noticeable. The amount of metal offeirng at the price quoted is small. After the recent flurry in lead, the price has now steadied to 7½c, and will likely remain there for some time. English lead, of course, is higher, but is being kept for home consumption. Galvanized sheets remain the same as last week with very few importations.

Toronto, Ont., June 29, 1915.—Comparatively few orders for shells have been given out during the past two or three weeks; the reason for this may possibly be found in the statement recently issued by the Shell Committee. It appears that only fixed ammunition is required by the British Government which means that all shells made in Canada will have to be complete before being shipped and not just the cases as formerly. More plants will now have to be equipped, or existing ones extended for making cartridge cases and fuse plugs; the explosive and firing charge will also have to be added before shipment. It seems highly probable that under the new conditions much larger orders for shells will be distributed among Canadian plants. With the addition of French and Russian orders, the outlook is distinctly favorable in this industry.

The situation is improving as regards foreign business and interesting developments are expected. The Canada Car & Foundry Co. is negotiating with the French and Russian Governments for large orders for railroad cars, while the same company has received an order for 600 freight cars for the Intercolonial Railway. The Canadian Locomotive Co. will build 15 locomotives also for the Intercolonial Railway. Other orders have already been placed with Canadian concerns for rolling stock, one of the latest being for 1,300 freight cars for the Northern Railway of France, to be built by the National Steel Car Co. of Hamilton, Ont. Taken in the aggregate, these orders represent a large amount of money and will also help an industry which has been dull for many months.

There are good prospects of further orders for army supplies and equipment, other than munitions, coming to this country. It is understood that Sir Thomas Shaughnessy has made arrangements with the British Government for the purchasing department of the C.P.R. to be used as a medium for obtaining the necessary equipment, etc.

Steel Market.

The general situation in the steel market is unchanged. The chief interest lies in the demand for rounds for shells; the tonnage is steadily increasing and will continue to do so as further orders are expected for Russian and French shells in addition to the requirements of the British Government. The orders for cars and locomotives referred to above will help the steel trade and there are possibilities of developments in export business in other steel products.

Domestic trade is not showing much improvement as industrial conditions are quiet, apart from the orders induced by the war. The building trade is still quiet, but municipalities are showing a little more activity as regards their requirements for cast iron and steel pipe. The tonnage will be much below last year on account of the difficulty being experienced in financing new works. Prices on steel products generally are firm but unchanged. There has been no further change in the quotations on galvanized sheets. The situation in the galvanizing trade is no better, notwithstanding the further weakness in the spelter market last week. The price of spelter is too high for it to be utilized in the manufacture of galvanized sheets and some makers still refrain from quoting.

Higher prices for galvanized pipe are announced. This advance has been caused by the high cost and scarcity of spelter, present prices being almost prohibitive for galvanizing. New basing discounts are given in the selected market quotations. There is no change in black wrought iron pipe.

The steel market in the States has been considerably stronger during the past week and prices are holding very firm. The export market has been very active with orders for rails, cars, locomotives and munitions. Indications point to increasing export business and an improvement in the domestic demand.

COMING CONVENTIONS.

American Foundrymen's Association, Atlantic City, N.J.—Sept. 27-Oct. 1.

Foundry and Machine Exhibition Co., Atlantic City, N.J.—Sept. 25-Oct. 2.

CANADIAN GOVERNMENT PURCHASING COMMISSION.

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George Gault, Winnipeg; Henry Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

Pig Iron.

The market is featureless and little business is passing. Prices are unchanged.

Scrap Metals.

Prices on copper and brass scrap continue very firm and good business is reported. Scrap lead and zinc have a weaker tendency, but are unchanged. There is little interest being shown in iron and steel scrap, and the market is dull and stationary. Prices are given in the selected market quotations.

Machine Tools.

Inquiries for machine tools have fallen off to some extent due, it is said, to the fewness of orders for shells lately. Dealers, however, are exceptionally busy filling orders already placed and a resumption of inquiries is expected any time. Prices of machine tools continue in an upward direction and some makers have effected further advances ranging from 10 to 15 per cent. Many machinery manufacturers are sold months ahead and consequently deliveries are away behind. When the orders for 4.5 shells are more numerous, greater activity in the trade is anticipated. The principal demand at the present time is for machines and tooling fixtures for making 18-pdr. high-explosive shells. Special machines are being developed for performing some of the operations.

Supplies.

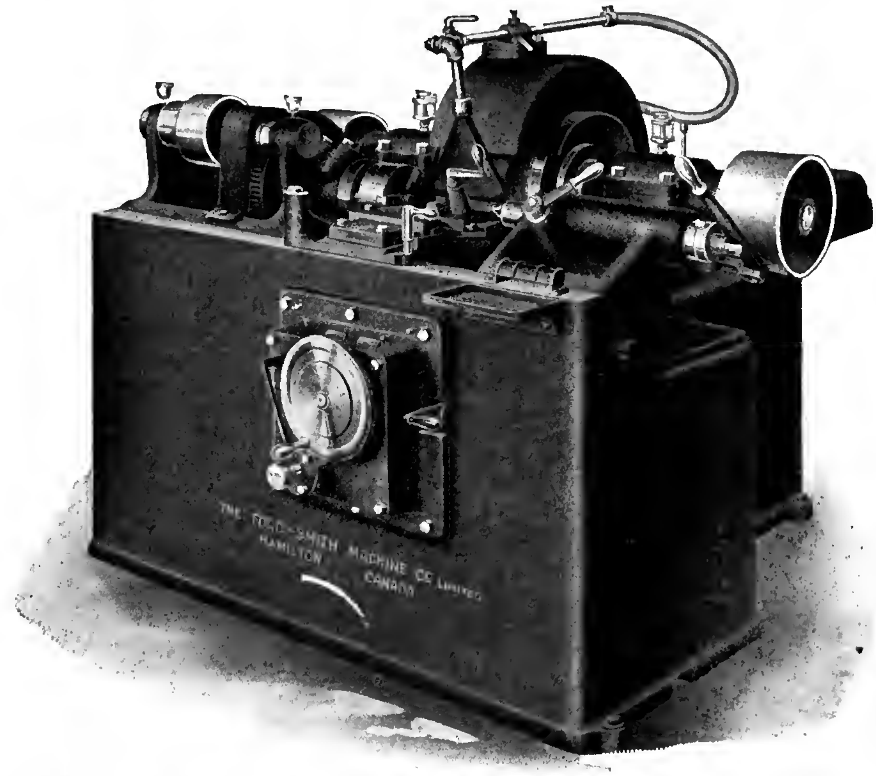
The activity in the supply business continues and dealers report satisfactory orders, principally in connection with shell plants; waste, twist drills, tool steel, chucks, belting, cutting compounds, etc., all being in good demand. Linseed oil has declined 5c and is now quoted at 73c per gallon for raw oil. Turpentine is firmer and has advanced 1c, being now quoted at 66c per gallon. Rope prices are very firm and may advance; red lead also may go higher.

Metals.

The markets generally are firm but there are no important price changes to note except spelter, which has recovered and is again on the up-grade. The spelter market is very unsettled and it is almost impossible to size up the situation. Tin is dull but the market is very firm and higher. Copper is unchanged and quiet. Lead is steady after the reaction reported last week. Antimony and aluminum are firm, the latter having advanced.

Tin.—The market is firm but dull, and

The Ford-Smith One Operation Shrapnel Shell Grinder



A Powerful Extra Heavy Grinder for finishing Shrapnel and General "Wide Wheel" Grinding.

This machine, using an Abrasive Wheel 20" dia. x $8\frac{1}{4}$" face, grinds both body of shell and nose as quickly as the lighter type general purpose precision grinders can grind the body alone.

Depending on the amount of stock left for finishing, we grind from fifteen to sixty-five shells without re-trueing the wheel.

POWER—Two 6" Belts drive the Emery Wheel Spindle, one 4" Belt with one to four gearing drives the shell.
RIGIDITY—Machine weighs 7,000 pounds of carefully distributed metal with an absolute absence of vibration.
CONTROL—Necessary levers, etc., all in front, the wheel trueing device swings into position when required.
ABRASIVE WHEEL is held solidly between two $3\frac{3}{4}$" bearings, on Safety Flanges, and six to 10,000 shells can be ground before renewing.

We have thirty-five of these machines in operation, doing from one hundred and forty to two hundred shells per ten hours, according to amount of stock left on the shell.

It will pay you to investigate this machine in comparison with your lathe work, or other grinder performances.

GET IN TOUCH WITH US TO-DAY

The Ford-Smith Machine Co., Limited

HAMILTON, CANADA

buyers are showing little interest. There is hardly any spot demand and very little inquiry for futures. The local market for tin has advanced 1c, and is quoted at 46c per pound.

Copper.—The market is higher in London, but unchanged in New York. There is no change in the situation as far as the big producers are concerned, as they are pretty well sold up for two months ahead. Quotations are unchanged at 21½c per pound.

Spelter.—The market has recovered and is very strong. This recovery was started by important interests advancing their prices. The advance was apparently quite unexpected in the trade, and buyers do not know what is at the back of this movement. The market is very unsettled and it is difficult to say what will develop. Spelter has advanced 2c and is nominal at 28c per pound.

Lead.—The market is firm and the Trust continues to hold their quotations at 5.75c. New York. There is a better tone in the market, but business is quiet. Local quotations are unchanged at 7½c per pound.

Antimony.—The market is quiet but very firm. The situation is unchanged, and the consumption continues to increase. Quotations are nominal at 40c per pound.

Aluminum.—A shortage of this metal has developed and the market is very strong. Local quotations have advanced 5c and are nominal at 35c per pound.

St. John, N.B., June 26.—A new industrial plant has been established in St. John—the St. John Milling Co.,—which is now operating its factory on west side, turning out fifty barrels of flour daily. For several months past mill-wrights, engineers, and other workmen have been busily engaged in installing and arranging new machinery of improved type in the mill, and the work has at last been completed.

While in St. John this week, Hon. J. D. Hazen, Minister of Marine and Fisheries, and late Acting Minister of Militia, sounded the trumpet call to Canadian manufacturers to help in the production of shells and other war munitions. In this city, at least two foundries are occupied in their manufacture, while other concerns are busy with other war orders. There must, however, be many plants which with a little renovating and alteration, could be adapted to the manufacture of shells, and Hon. Mr. Hazen said he would like to see them aid in this connection.

Lieut. Donald Fisher, of the Royal Canadian Dragoons, has been wounded in action in France. His friends will be pleased to learn that his injuries are reported not to be serious. Lieut. Fisher is a son of W. Shives Fisher, of Emerson & Fisher, proprietors of the Enterprise Foundry, at Sackville, N.B. He left here with the first Canadian contingest.

ONTARIO HYDRO-ELECTRIC SYSTEM.

THE total revenue from the 84 municipalities, railways and users of the Niagara Circuit of the Hydro-Electric System for the six months ending May 1, is $710,324.95, according to the official report made to the Commission by the chairman, Sir Adam Beck. After providing some $303,000 for the cost of power, $49,000 for maintenance, $155,000 for interest, $30,000 for operation, $156,000 for engineering and construction, the sum of $69,908.37 has been applied to the sinking fund, and $50,210.35 to the depreciation and reserve account. The average horse-power consumed per day during the half-year has been 75,281.

An order was made upon the Ontario Power Company for an additional 100,000 horse-power, and at present 90,000 horse-power is being taken. The present call is accordingly for the last 10,000 horse-power available under the existing contract, and on the recommendation of Sir Adam Beck the Commission decided to investigate and report to the Government, probably within two weeks, various schemes under which the supply of power in this part of the province may be largely increased.

In addition to the Niagara supply, the Commission is now securing between 4,000 and 5,000 horse-power from the Ottawa development, 2,000 from the Port Arthur, 2,000 from Big Shute, 2,000 from Wasdell Falls, and plans to serve the Grey and Bruce district from Eugene Falls.

In St. Thomas and Galt, where the greatest reductions have been made, the surpluses, after paying debenture debts, overdrafts and other charges are reported as $4,072.74 and $2,209.45, respectively. In the city of Toronto, for the quarter ending March 31, after paying all fixed charges including sinking fund the surplus is $31,715.91.

ALLIES PURCHASING AGENTS.

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:—

International Purchasing Commission, India House, Kingsway, London, Eng.

British.—Col. A. G. Barton and F. W. Stobart, Ritz Carlton Hotel, Montreal.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendance Ministere de la Gnerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminister, London.

Russian.—Messrs. S. Ruperti and Aieksieff, care Military Attache, Russian Embassy, Washington, D.C.

DEMAND FOR ANTIMONY.

IN each British 18-pounder shrapnel shell there is approximately one pound of antimony. The shrapnel bullet is composed of 87½ per cent. lead and 12½ per cent. antimony, and the total weight of the bullets in the shell is close to eight pounds.

The enormous production of shrapnel, including shells now in course of manufacture, already has reached a total that is far in excess of the U. S. imports of antimony for last year. Imports then were in excess of 14,000,000 pounds. However, there were produced close to 25,000,000 pounds of antimonial lead in that country in 1914. The antimony content was about 2,500,000 pounds.

"The situation in respect of supplies is less acute than early in May," says the Wall Street Journal, "when the tension in affairs between Japan and China threatened to shut off the only present foreign source of supply for the United States. The apparently more friendly relations between those two countries has reassured the American manufacturers, especially the type makers—the commercially big users of antimony.

SHELL COMMITTEE STATEMENT REGARDING SHELL ORDERS.

THE Canadian Shell Committee, of which General Alexander Bertram is chairman, has prepared a statement for the press in explanation of the remarks of Lord Curzon in the British House of Lords on June 23. Lord Curzon is reported to have said that the British Government desired to obtain all possible material from the Dominions but Canadian makers did not make shells complete, and had to go to the United States for component parts. He added that "delivery from Canada had been exceptionally bad."

It is understood that the "bad delivery" refers only to shells ready for use. Hitherto, to complete the shell, certain importations have had to be made from the United States, but steps were taken some time ago to overcome this difficulty, and it is hoped that in a very few weeks it will be completely removed.

The statement of the Shell Committee is as follows:—

"The attention of the Shell Committee has been called to observations attributed to Lord Curzon in the House of Lords recently. The undertaking of the Shell Committee for deliveries of empty shells has been thoroughly fulfilled and empty shells to a larger amount than those delivered could be forwarded immediately if desired by the War Office.

"The British Government, however, have notified the Shell Committee that future deliveries must be of fixed ammunition and that the further production of empty shells is no longer required. To convert the empty shell into fixed ammunition involves the purchase of machinery and the establishment of the necessary organization by industrial companies of Canada, who were prepared to undertake the work.

"The success which has attended the efforts for that purpose is regarded by the Shell Committee as thoroughly satisfactory, but it can readily be understood that the capacity to produce empty shells in Canada far exceeds the capacity of the organization only recently established to convert empty shells into fixed ammunition.

"The 650,000 shells which up to a couple of weeks ago had been shipped from Canada were empty shells. Since then complete shells have been going forward in small quantities and it is now assured that hereafter they will be shipped in increasing numbers.

"For obvious reasons, the official reply to criticisms has been hitherto that Canada was filling all the orders it had received, but Lord Curzon's remark has led to the fuller explanation of now. For completed shells Canada will get all the orders it wants, and it is to the turning out of completed shells that all the energies of the Shell Committee are now bent."

The expression "empty shells" refers of course to shells without fuses and in which the explosive is lacking.

Herbert M. Ewan has resigned from the position of sales manager of the Canadian Steel Foundries, Ltd., Montreal, and will join the firm of Taylor & Arnold, Ltd., dealers in railway supplies and locomotive specialties, Montreal and Winnipeg, as vice-president; the change to take effect on July 1. Mr. Ewan who was born in Montreal, has been connected with the Montreal Steel Works and Canadian Steel Foundries for over eleven years, latterly in the capacity of sales manager. He has had considerable experience in England and the United States as well as in Canada of the steel and railway supply business.

A. R. McPherson, manager of the Windsor Foundry & Machine Co., is recovering from his recent serious illness.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Goderich, Ont.—The Paget Grain Door Co. will make motor trucks.

Pictou, N.S.—A new smoke stack will be erected at the electric light plant here.

Lachine, Que.—The Lachine Gas Mfg. Co. will make an extension to their plant.

Milton, Ont.—Machinery for making shells is being installed in the local screw factory.

New Glasgow, N.S.—A fire on June 13 damaged F. W. Cummings' machine shop to the extent of $5,000.

Lindsay, Ont.—Arrangements are being made at John McCrae's foundry to install machinery for making shells.

Welland, Ont.—The Standard Construction Co. are the contractors for the addition to the plant of the Canadian Billings & Spencer Co.

Toronto, Ont.—Dominion Wheel and Foundry Co. will build a one-storey frame and galvanized addition to their foundry, 131 Eastern Avenue, to cost $5,000.

Toronto, Ont.—The Commissioner of Works, R. C. Harris, has recommended the purchase of two electrically-driven pumps for the High Level Pumping Station, with a capacity of 7,500,000 gallons each per day.

Petrolia, Ont.—A by-law will be voted on by the ratepayers on July 14 to authorize the expenditure of $35,000 on the construction of a new electrical distribution plant or the purchase of the plant of the Petrolia Utilities Co.

Toronto, Ont.—The Steel & Radiation Co. have applied for a permit to erect a one-storey brick addition to their factory at 19 to 21 Fraser Avenue, at a cost of $2,500. The building is to be used for the manufacture of ammunition.

Farnham, Que.—A meeting of the Board of Trade was held on June 22. The manufacture of munitions of war was discussed and a committee was appointed to go fully into the matter, and endeavor to establish a plant for the purpose.

Montreal, Que.—Dominion Bridge Co., which has developed one of the largest shell-making organizations in Canada, is now constructing an extension to its works at Dominion. The new plant, which is designed for work on high explosive shells, will cover about an acre of ground.

Electrical

Winnipeg, Man.—An extension will be made to the King Street sub-station.

Sarnia, Ont.—Hydro-Electric system may be adopted here. The commission's engineers have valued the Sarnia Gas & Electric Co. plant at $155,000.

Exeter, Ont.—A by-law to provide $20,000 for the installation of a Hydro-Electric system is being considered by the Town Council. Clerk, J. Senior.

Ailsa Craig, Ont.—By a vote of 132 to 4, the ratepayers of Ailsa Craig carried a hydro-electric enabling by-law last Monday. The installation of the system will cost $7,000.

Leamington, Ont.—The Town Council are considering the question of installing a hydro-electric system. The Commission's engineers have been requested to submit an estimate as to the cost.

Kincardine, Ont.—The Water and Electric Light Commission has decided to purchase 44 nitrogen electric lamps and brackets to replace the 18 arc lights on the streets, which have not given satisfaction.

Toronto, Ont.—The Provincial Hydro-Electric Commission has awarded contracts for the construction of stations at Owen Sound, Chatsworth, Dutton, Thamesville, Ridgetown, Blenheim and Bothwell, and authority is given to construct lines to those stations.

Contracts Awarded

Woodstock, Ont.—The George H. King Co. has been awarded a contract for 25,000 ammunition boxes at $24,000.

Dorchester, Ont.—Richard Waltham, of Kerwood, has been awarded the contract for the masonry of Elgin bridge, at $2,900, whilst the steel work goes to the Dominion Bridge Co. of Toronto at $3,685.

Hespeler, Ont.—A contract has been let to the Des Moines Steel Co., of Pittsburg, Pa., for a 100,000 gallon standpipe. Contracts have not yet been awarded for pumping machinery. Bowman & Connor of Berlin, Ont., are the engineers.

Sidney, N.S.—Reid McManus, of Memramcook, has been awarded the contract for the construetion of a spur line connecting the main line of the Intercolonial Railway with the new pulp mill erected by the Bathurst Lumber Co. The contract price is $61,000.

Owen Sound, Ont.—Messrs. Grier & Lethbridge, contractors, have been advised by the Hydro-Electric Commission that their tender for the Hydro-Electric transformer station here has been accepted. The contractors will commence the work of clearing the ground and the erection of the building at once.

Selkirk, Man.—The Department of Public Works, Winnipeg, have let the contract for the construction of an elevated water tank at the Hospital for the Insane, to the Chicago Bridge & Iron Works, Bridgeburg, Ont., at $7,300, and for the installation of a steam pump to the General Supply Co., of Canada, Ltd., Winnipeg, at $1,050.

Tenders

Toronto, Ont.—Tenders will be received up to Tuesday, July 6, 1915, for the supply of: 55—A—Two portable crossovers, right and left-hand turnouts, and No. 60 rail: 64—One steam pump, complete, for hydraulic operation of gate valves, high level pumping station; 65—Air compressor, with motor, Danforth avenue car barns. Tenders must be addressed to the chairman, Board of Control, City Hall. Specifications and forms of tender may be obtained at the Works Department, City Hall.

Ottawa, Ont.—Tenders will be received until Monday, July 12, 1915, for the construction of the superstructure for a bridge, consisting of four spans, over the Quinze River at North Timiskaming, Pontiac County, Que. Plans and forms of contract can be seen and and specification and forms of tender obtained at the Department of Public Works, Ottawa, and at the offices of the District Engineers, Shaughnessy Building, Montreal, P.Q.; Confederation Life Building, Toronto, Ont.

Trade Gossip

London, Ont.—Sir Adam Beck announced on June 24 that the official opening of the electrified London and Port Stanley Railway would take place on July 22.

M. Beatty & Sons, Welland, Ont., have obtained an order from the War Purchasing Commission for a large number of hoisting engines, centrifugal pumps and clamshell buckets.

Hamilton, Ont.—It is reported that the National Steel Car Co., has secured an order for 1,300 railway freight cars from the French Government. The contract is estimated at $1,250,000.

Sidney, N.S.—It is reported that the Aetna Explosive Co., of New York, will establish a plant here. A. J. Moxham is connected with the company which has been granted a Dominion charter.

Kingston, Ont.—The Canadian Locomotive Company has received a rush order from the Dominion Government for fifteen heavy engines to be used on the Intercolonial Railway. Work on them has already begun.

Montreal, Que.—The Montreal Ammunition Co., a subsidiary of the Dominion Bridge Co., which has rented the plant of the National Bridge Co., will be ready to start manufacturing operations on war munitions in about a month. The plant and equipment are now being installed.

Ottawa, Ont.—It is reported that the dry dock at Prince Rupert, B.C., will be sufficiently advanced to enable shipbuilding to start by next August. The last pontoon was launched recently and the upper works are being proceeded with. The dry dock when finished will have cost some $3,000,000.

Vancouver, B.C.—As a result of another meeting of the creditors of the Heaps Engineering Co. held here recently, an agreement has been arrived at which, if satisfactory to the bondholders, will remove all obstacles in the way of utilizing this modern plant for the manufacture of munitions of war.

Walpole Rubber Co.—Letters patent have been issued to the Walpole Rubber Co. of Canada, Ltd. This refers to the reorganization of the concern at Granby following a recent change of ownership, in which Canadian Consolidated Rubber was directly concerned. Little information has been made public as to detail of plans regarding the operation of the subsidiary.

Hamilton, Ont.—The National Steel Car Co. has secured another big war order. Basil Magor, general manager, has been in close touch with the French Government for some months, and on Saturday he stated that articles were practically signed for the delivery of 1,300 railway freight cars for use on the Nord Railway. The contract is estimated at $1,250,000.

Training the Unskilled in Shell-making.—Men unskilled in lathe operation, but who are desirous of taking a hand in the manufacture of shells in Sheffield, England, are being given two weeks' thorough training in this feature at the University Applied Science Department, after which they pass to the armament works to do what they can there.

M. Beatty & Sons, Welland, Ont., were successful in getting an order from the War Purchasing Commission for five carloads of material-handling machinery, made up of hoisting engines, derrick irons, turntables, centrifugal pumps and clamshell buckets, all of which will be used by the Overseas Construction Corps in Europe. The order was received on Saturday, May 29, and the goods went forward knocked down and packed for ocean shipment on June 1.

Ottawa, Ont.—An agreement has been reached between Hon. Frank Cochrane and the Grand Trunk Pacific Railway for the leasing of the Lake Superior section of the N. T. R., which runs from Graham, Ont., to Fort William, Ont. Pending its signing, there will be no official announcement, but it is understood that the lease is in the neighborhood of $600,000 a year, which is about 4½ per cent. of the original cost of the line.

Canadian Electrical Association. — At a meeting of the member companies of the Canadian Electrical Association, held at Ottawa last Saturday, the following officers were elected: President, Lieut.-Col. D. R. Street, Ottawa Electric Co.; first vice-president, D. H. McDougall, Toronto Electric Light Co.; second vice-president, W. S. Roberts, Electric Power Co., Toronto; third vice-president, W. G. Matthews, Quebec Railway, Light and Power Co.

Stratford Lodge, C.A.S.E.—At the regular meeting of Stratford Lodge, No. 31, C. A. S. E., the following officers were elected for the current term:—Past president, Alex. Scrimgeour; president, J. Schafer; vice-president, J. Hickman; secretary, J. A. Robertson; recording secretary, G. L. Frame; treasurer, George Hird; conductor, J. F. Smith; doorkeeper, Maxwell Mongraw. Delegates to convention at Hamilton on July 20, 21 and 22, Alex. Scrimgeour and Peter Steinman, Tavistock; alternates, Geo. L. Frame and J. F. Smith.

Russian Car Orders.—A first visit was paid to Montreal on June 23, by Maximilian Groten, chief mechanical engineer for the Russian Imperial Railways, attached to the Russian Ministry of Ways and Communications, Petrograd. Mr. Groten came to Montreal to look over the car plants here in connection with large orders placed by the Imperial Russian Government for steel frame box cars. The Russian Government has ordered 2,000 of these cars from the Eastern Car Company of New Glasgow, N.S., and 18,000 similar cars from a number of firms in the United States. Mr. Groten had visited the works of the Eastern Car Co. at New Glasgow, and also the plant of the Nova Scotia Steel & Coal Co., previous to coming to Montreal.

Municipal

Oshawa, Ont.—On July 10, a by-law will be voted on to raise $8,000 to bonus a firm proposing to make shells.

Canora, Sask.—A by-law will be voted on by the ratepayers on July 9, to raise $17,700, for completing the waterworks system.

Preston, Ont.—A by-law to loan the Hurlbut Shoe Co. $25,000 was carried here on June 21 by a majority of 126 over the two-thirds vote necessary.

Unionville, Ont.—The Village Council are having plans for a waterworks system prepared by James, London & Hertzburg, engineers, 79 Adelaide Street E., Toronto.

Mimico, Ont.—The Council has decided to secure water from New Toronto. It is the intention of the Council to proceed with the installation of the water mains.

Watrous, Sask.—C. McManus & Co. have been instructed to proceed with extensions to the water distributing system. Some 8-in. cast iron pipe will be required.

Woodstock, Ont.—The Town Council are considering making extensions to the waterworks system. F. A. Barbour, of Boston, Mass., has been engaged as consulting engineer.

Fredericton, N.S.—The City Council contemplate installing a new fire alarm system, which is estimated to cost $1,200. T. S. Wilkinson is chairman of the Fire Committee.

Windsor, Ont.—The City Council are in the market for a quantity of cast iron pipe and specials, geared valves, fire hydrants, pig lead and valve boxes. W. A. Hanrahan is secretary of the Water Commission.

Bassano, Alta.—The by-laws authorizing the expenditure of $10,000 for completing the town's gas-well and piping the gas was carried. The by-law will likely receive its third reading at the next council meeting.

Lindsay, Ont.—A by-law to authorize construction of certain extensions of water mains has been given its several readings, as well as a by-law providing $6,000 by way of debentures to provide for cost of construction of same. All the extensions outlined in by-law have been constructed.

Chatham, Ont.—As soon as the necessary arrangements have been made, a by-law will probably be submitted to Chatham ratepayers providing for the raising of about $18,500, the amount that it has been proposed for the city to give towards the purchasing of the site of the Dominion Sugar Co. for its $1,000,000 sugar plant to be erected just outside the city.

Personal

Guelph, Ont.—Applications are being received by T. S. Moore, city clerk, for a city engineer.

E. J. Holland, who recently resigned his position as city engineer of Guelph, Ont., will engage in private work in Western Ontario.

Leslie Brinkman, of St. Thomas, Ont., has been appointed assistant to the chief engineer of public works, with headquarters at Fort William, Ont.

W. A. Black, vice-president and managing director of the Ogilvie Flour Company, is making an extended tour of the Canadian West to get into direct touch with the crop and milling conditions.

D. R. Hanna has retired from the firm of M. A. Hanna & Co., Cleveland, Ohio, sales agents for "Victoria" pig iron produced at Port Colborne, Ont. Mr. Hanna was admitted to the firm in 1891.

A. W. Mace has resigned his position with the Factory Products, Ltd., Toronto, Ont., temporarily, to give assistance in the war munitions department of the United States Steel Products Co., New York City.

Frank F. Barber has resigned his position as manager of the machine tool department of the Canadian Fairbanks-Morse Co., Toronto, and will be connected with the machine tool department of the A. R. Williams Machinery Co., Toronto, Ont.

Douglas J. Peake, until recently with the United States Cast Iron Pipe & Foundry Co., Burlington, N.J., has been

appointed foundry engineer and assistant to the general superintendent of foundries of the Canada Iron Corporation. Two years ago, Mr. Peake was connected with the Three Rivers, Que., plant of the latter concern.

Catalogues

Generating Sets.—Enberg's Electric and Mechanical Works, St. Joseph, Mich., are distributing bulletin No. 101, describing their direct-connected dynamos and engines, made in sizes ranging from 1 to 50 k.w. The bulletin contains a comprehensive description covering the design of both engine and dynamo. It is fully illustrated and tables are included giving the weights and principal dimensions.

Slotting Machines.—Catalogue No. 49 recently issued by the Newton Machine Tools Works, Inc., Philadelphia, Pa., deals with the complete line of Newton standard and special slotting machines. The catalogue also contains a number of illustrations showing an interesting line of milling machines, rotary planers and cold metal saws, etc. The illustrations are very clear and give a good general idea of their construction. They are accompanied by tables giving the principal dimensions covering the various sizes.

Motor Trucks—The "Knox" tractor is described fully in an attractive catalogue recently issued by the Knox Motors Associates, Springfield, Mass., who are the distributors. The big feature of the Knox tractor, as claimed in the catalogue is that it will haul any kind of load in any type of trailer. Among the illustrations are views showing several types of trailer while others show the tractor and engine. A specification is included covering the model 35 tractor.

Motor Generator Sets made by the Canadian General Electric Co., Toronto, are the subject of a 28-page bulletin No. 42552, recently issued. The bulletin contains a lot of useful information on various types of motor generator sets and their field of application. The construction of these machines and matters relating to their operation are dealt with in an exhaustive manner. An interesting feature of this bulletin is a number of half tones of motor generator sets of various types showing their wide range of application. The bulletin is exceedingly well gotten-up and the half tones are very good reproductions. Copies may be obtained by interested readers upon application.

Book Reviews

Preventing Losses in Factory Power Plants, by David Moffatt Myers 560 pages; $7\frac{1}{2}$ in. x 5 in.; 68 illustrations. Published by the Engineering Magazine Co., New York. Price $3. This is a new work, and is an addition to the Works Management Library. The book has been written expressly for the use of the owners and managers of manufacturing industries with the object of setting forth in as brief and direct a manner as possible the basic information which they require for the intelligent handling of their power plant problems. The first nine chapters cover these matters in a general way, but easily assimilated, while the remaining nine chapters deal with the subject in greater detail, and are more especially of value to the mechanical superintendent and engineer. The subjects treated successively in the initial nine chapters are as follows:—Determination of existing losses, attainable efficiency and ordinary wastes, the boiler plant, steam piping and engine plant, preventable losses in the engine plant, and the heating system. The ninth chapter dealing with the "Human Factor," the author considers to be of the greatest importance. The succeeding chapters deal with efficiency systems for boiler plants, boiler tests, combustion, surface combustion, natural gas as a boiler fuel, natural gas for the gas engine versus the steam engine, the economic combustion of waste fuels, boiler feed pumps, modern types of prime movers, while the concluding chapter is devoted to reports and their compilation. From the above it will be gathered that the book contains a great deal of useful information for those desiring to improve the efficiency of their plants. While the subject matter is not necessarily new, it has the advantage of being brought together and presented in a convenient form so that the relation of the various subjects can be studied together. By this means a more complete understanding of power plant problems is made possible. The book is printed in clear type, with diagrams and tables.

Sidney, N.S.—Mark Hurll, of Glasgow, Scotland, has been investigating the fireclay deposits in this district with a view to establishing a plant for making fire brick.

Lindsay, Ont.—A by-law submitted to the ratepayers to authorize payment of $65,000 to the Horn Brothers' Woollen Co. was carried here on June 24 by a majority of 311.

Weyburn, Sask.—E. R. Humphries, Regina manager for the Canadian Oil Companies, Ltd., was in town recently for the purpose of completing arrangements for locating a distributing station at this point.

Trade Gossip

Canadian Vickers, Ltd., Montreal, have sold a motor generator costing $5,400 to the city of Winnipeg, Man.

Heap & Partners, Canada, Ltd., Montreal, have been awarded a contract by the Ottawa city council for the supply and installation of a pump.

The Canadian Fairbanks-Morse Co., Toronto, have received a repeat order for an X-ray electric generator outfit for the Canadian Expeditionary Force.

The B. F. Sturtevant Co., of Canada, Ltd., Galt, Ont., have been awarded the contract for the heating and ventilating equipment for a new shop which the Canadian Locomotive Co. are building in Kingston, Ont.

The John Bertram & Sons Co., and its associate company, the Pratt & Whitney Co. of Canada, Ltd., announce change of Western office address to 1205 McArthur Building, Winnipeg. A. Martin is the Western representative.

Transcona, Man.—A notice has been issued to the effect that commencing today, July 1, 1915, the Dominion Government has taken over the operation of the Transcona shops, round-houses and work pertaining to this department between Winnipeg and Westfort.

Berlin, Ont.—A company has been formed with a capital of $100,000 to manufacture carburetors and vaporizers here. The patents are controlled by the Kerosene Burning Carburetor Co., of Detroit, Mich. Claude Forsyth of the John Forsyth Co., Berlin, is interested.

The Prince Rupert, B.C.—The Board of Trade published its annual report for 1914, together with general information as to the resources of the district of northern British Columbia. The report contains an interesting review of trade and commercial conditions at Prince Rupert, and indicates opportunities for industrial development.

Delay Shell Shipment.—Orders to delay shipment of any more shells for the present have been received by manufacturers, the instructions being that these should be held until further notice. While no information was given as to the reason for the order, it is felt that it is due to the shell cases being turned out more rapidly than they can be filled with explosives for shipment to England.

Dominion Steel Production.—The Dominion Steel Corporation production for the month of June, with comparisons, was as follows:

	1915, tons.	1914, tons.
Pig iron	22,552	21,111
Steel ingots	28,680	26,629
Rails	13,044	16,998
Rods	6,435	1,981
Bars	797	2,347
Wire and wire products	3,167	1,541
Coal mined	481,820	485,449

Customs Receipts Show Increase.—For the first time in a considerable period, Customs receipts for the month just closed, June, show an increase over the same period last year. This is an indication that the new war taxes are beginning to take effect. Customs receipts for June were $7,315,638.74, as compared with $7,274,763.32 in June, 1914, an increase of $40,875.42. For the three months ending June 30 the total Customs receipts were $20,907,939.88, or $772,530.66 less than during the corresponding period last year.

Halifax, N.S.—At a Board of Control meeting on June 30, the directors of the Nova Scotia Car Works, Ltd., asked the city for an additional $125,000, as further capital is declared by directors to be absolutely required to successfully carry on its business. The city originally advanced $125,000 and a portion of this loan has been paid off by instalments. The additional amount asked for will bring the company's liability to the city up to $250,000, and the amount will be secured by mortgage in same manner as previous advance.

Canadian Trade.—The possibilities of increased trade between Russia and Canada are now being seriously considered. Until a short time ago Canada did no business direct with Russia. In 1913, out of our $2,145,000 of exports to Russia no less than $2,017,000 passed through the United States. Similarly Russian products were brought to Canada in foreign ships. Now the Canadian Pacific Railway are establishing a line of steamers between Vancouver and Vladivostock, and it is expected that an increased and direct trade will be built up between the two countries.

Shell Shipping Boxes.—The Shell Committee, Stephen Building, Ottawa, have issued the following additional details in connection with the specifications for shell boxes. In reference to the screw used to secure the cover in the 4.5 shell box, we would say that you have the alternative of using No. 12 x 1¾ ins., or No. 14 x 1¾ ins., and that there is to be only one screw in each end and two in each side, suitably spaced. Further, the cleats on the cover are to be made ⅝-inch instead of ½-inch. Also, the lumber throughout the box may be dressed to an even thickness not less than ⅞-inch.

The Canadian Car & Foundry Co., Montreal, has received an order from the Railway Executive Committee of the British War Office for 1,200 four-wheel, continental type, 22-ton, steel frame box cars. The value of the order was placed at $1,200,000 by W. W. Butler, senior vice-president, who states that the cars will be manufactured at the company's local plants. Manufacturing operations will be started immediately. Mr. Butler explained that the cars were to be used in connection with military operations of the British army in northern France. The specifications of the equipment conformed in every respect to the standards of the French railways.

Canadian Car Co. Shell Contract.—It is understood that the loading of shrapnel and high explosive shells by the Canadian Car & Foundry Co. in its $83,000,000 contract with the Russian Government was not included in the original contract, but that it was arranged for later at the request of the Russian Government. Construction of the factory for assembling and loading of the shells near Lyndhurst, N.J., is not expected to be completed for about a month. No exports of shells by the Canadian Car Co. are looked for before the early part of August, although shipments of parts to assembling points by American manufacturers to whom the contract was sub-let will be well under way before then.

Large Equipment Orders.—Further equipment orders have been placed this week. The Federal Government has ordered 15 locomotives, to cost $22,000 each, from the Canadian Locomotive Co. of Kingston. An order has also been placed for 1,000 box cars for the National Transcontinental Railway. This contract has been placed among three concerns—the Canadian Car and Foundry Co., the National Steel Car Co., and the Nova Scotia Car Co. The Canadian Locomotive Co. is already working on a Russian Government order for 50 locomotives, while the Eastern Car Co. has an order for 2,000 cars also from the Russian Government. Canadian Car & Foundry Co. have a Dominion Govern-

ment order for 600 standard freight cars for the Intercolonial Railway.

Canada's Metal Production.—Last year Canada produced metal and metallic ores valued at \$58,870,000. Copper contributed 75,000,000 pounds at an average price of 13½ cents; gold, 770,000 ounces, valued at \$15,925,000; lead, 36,000,000 pounds at 4½ cents; nickel, 45,000,000 at 30 cents a pound; silver, 27,500,000 ounces at 54.8 cents; and zinc ore, 13,000 tons, valued at \$310,000. The war has affected metals in various ways. Copper is now selling at 20 cents a pound, nickel about 50 cents a pound, while lead and zinc also show advances in price. The only exception to the general increase is silver, which is now selling about 5 cents an ounce less than last year. It is estimated, however, that the heavy demand for munitions means \$20,000,000 to Canada's mine owners.

Tenders

Bathurst, N.B.—Tenders are being called for the construction of a power house, pumping station, stand pipe, water mains, etc.

Winnipeg, Man.—Tenders addressed to the chairman, Board of Control, will be received up to Friday, July 16, 1915, for the supply of electrodes, glassware and arc lamp cutouts for the City Lighting Department. Instructions to bidders, specifications and form of tender may be obtained at the office of the City Light & Power Department, 54 King street.

Ottawa, Ont.—Tenders for incandescent lamps for public buildings, will be received Tuesday, July 13, 1915. Specifications may be seen on application to Thos. A. Hastings, clerk of works, Postal Station "F," Toronto; to R. L. Deschamps, overseer, Dominion Buildings, Montreal, and to the chief architect, Department of Public Works, Ottawa.

Contracts Awarded

Walkerton, Ont.—The Knechtel Furniture Co. has received an order for 25,000 boxes to hold 4.5 howitzer shells.

Orillia, Ont.—The Orillia Furniture Co. have received an order to manufacture 25,000 ammunition boxes for the British Government.

The Hamilton Bridge Works Co., Hamilton, Ont., have been awarded the contract for the construction of a new steel swing span to cross the lock at Lindsay, Ont.

Hespeler, Ont. The Hespeler Furniture Co. and the W. A. Kribs Co. have received orders for shell and ammunition boxes. These orders will necessi-

tate the installation of special machinery.

Transcona, Man.—At a special meeting of Town Council on June 29 the contract for the pumps for the sewage reservoir was awarded the British Canadian Engineering Co., at \$3,174.34. It was decided to purchase 1,500 feet of fire hose from the Gutta Percha Co. at 80 cents per foot.

Personal

Peter H. Cowan has commenced his duties as waterworks superintendent of the City of Galt, Ont., succeeding Mr. Bartleman, who resigned.

J. C. Rockwell, manager of the Lunenburg Foundry Co., Lunenburg, N.S., died at that place on June 29. Mr. Rockwell, who was born in Cornwallis, N.S., 50 years ago, had been manager of the Lunenburg Foundry Co. since 1899.

Thomas Chater, for 26 years the chief engineer of the Windsor electric lighting plant, died on June 28, aged 60 years. The deceased was born in England, and came to Canada when he was 15 years old. He has lived in Windsor for more than forty years.

Harry F. Barnes, a member of the city engineer's department of London, Ont., has been given an important post in China and sails for that country on July 27 to become instructor of railroad engineering in the State University of Tang Shang, South China.

H. T. Matthew has been appointed Pacific Coast representative for the Society of Electrical Development, New York City. Mr. Matthew was born in St. John, N.B., in 1878, and entered the employ of the McGraw Publishing Co., New York, in 1901, with whom he is still associated.

D. A. Thomas, M.P., who has been appointed munitions agent in Canada and the United States for the British Government, arrived at New York on July 5, on the American liner St. Louis. He was met at the pier by Ambassador Sir Cecil Spring-Rice and Willard D. Strait of J. P. Morgan & Co.

Col. W. M. Davis, formerly city engineer at Woodstock, Ont., and Berlin, Ont., has been selected to command the 54th Kootenay Battalion, which is now being organized at Vernon, B.C. Col. Davis was born at Aylmer, Ont., and graduated from the R.M.C., Kingston, Ont.

Capt. L. A. Demers, Dominion Wreck Commissioner, has completed the investigation into the stranding of the steamship Romney on Greene Island recently. Judgment will be given in a few days. The ship is now in the dry dock at Quebec having some new plates put on the bottom and others rolled again.

Catalogues

Vises.—A leaflet describing and illustrating the all-steel machine vises made by the Cincinnati Milling Machine Co., Cincinnati, O., has come to hand.

Metal Saw Table.—A bulletin describing and illustrating the Acme Metal Saw Table No. 2, manufactured by the Hub Machine & Tool Co., Philadelphia, Pa., has been received. This machine is adapted for cutting sheet copper and brass, tubes, fibre, rubber and other materials.

Centrifugal Compressors for blast furnaces, is the title of bulletin No. 48601, just off the press, and being distributed by the Canadian General Electric Co., Toronto. The advantages claimed for this type of blower over the reciprocating blowing engine are described in detail and the illustrations give a general idea of the design. These latter are supplemented by a description of the compressor including, of course, its principal features and method of operation.

Power Transmission Appliances.—The new "Oneida" line of power transmission appliances is dealt with in bulletin 03, issued by the Oneida Steel Pulley Co., Oneida, N.Y. The principal lines described include drop and post hangers, pillow blocks, couplings, etc. Their principal features are dealt with in detail and price lists give the code words and other useful information for the various sizes of each appliance. The bulletin is fully illustrated.

Cold Storage Doors made by the Jamison Cold Storage Door Co., formerly the Jones Cold Store Door Co., Hagerstown, Md., are dealt with in catalogue No. 7 recently issued. The construction of the "Jones" and "Noequal" cold storage doors, fireproof and non-fireproof is fully described, and is accompanied by illustrations showing the details as designed for coolers and sharp freezers, etc. Particulars are given of cold storage windows, also of revolving and sliding doors. The catalogue contains 96 pages with thumb index and is gotten up in an attractive manner.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Preston, Ont.—The Dominion Bronze Co. have started work on a large order for brass sockets for shells.

Bathurst, N.B.—The town will build a power house, boiler-room and pumping station. John G. Staut is town clerk.

Blenheim, Ont. — The School Board have decided to install a new heating system in the school to cost $2,500. R. L. Gosnell is chairman of the Board.

North Vancouver, B. C.—The Wallace Shipyards and North Shore Iron Works have their plants in readiness to start on the Imperial Government shell order.

Berlin, Ont.—The Water Commission has decided to purchase eight new 3-in. pumps and motors at a cost of $179 each. These will be used on the wells in place of the air-forcing system.

Hamilton, Ont. — The E. T. Wright Co., manufacturers of tinware are considering making a large addition to their factory. An enameling and aluminium plant will be included in the extension.

Thorold, Ont.—The laboratory building, on the premises of the Coniagas Reduction Co., about a mile east of Thorold, was destroyed by fire, together with its contents, on July 13. The loss is estimated at $10,000 which is covered by insurance.

St. Marys, Ont.—The firm of Weir & Weir, have advertised for a site in Stratford suitable for a mill. They claim that the Hydro rates in St. Marys are too high, that they cannot compete with waterpower, and in Stratford their competition would be steampower.

Niagara Falls, Ont.—Work on the construction of an aerial tramway over the Whirlpool has been started by the McLeod Contracting Co. of Toronto. The tramway is being constructed by the Spanish-American Tramway Co., a subsidary of a big Spanish amusement concern.

Municipal

Winnipeg, Man. — The city are considering a proposition for laying 12 miles of gas mains.

Sackville, N.S.—The Town Council have decided to purchase a pump and motor for the waterworks plant.

Rodney, Ont.—A by-law will be voted on by the ratepayers on July 26, to authorize the granting of a loan of $5,000 to the Rodney Woodware Co.

Chatham, Ont.—The city council have recommended the purchase of an aerial truck for the fire department at a cost of about $13,500. A by-law will be voted on.

Exeter, Ont.—By a vote of 247 to 7, the ratepayers of Exeter on July 16 endorsed a Hydro power by-law. The vote calls for the installation of a Hydro-Electric system here, at a cost of $20,000.

Petrolea, Ont. — Petrolea joined the hydro-electric union on July 14, by carrying with a majority of 385 to 10 a by-law calling for the expenditure of $35,000 for the installation of the hydro system. The contract calls for an initial consumption of 500 horse-power at $36.25 per horse-power per annum.

Ottawa, Ont.—The proposed Lemieux Island waterworks scheme includes the trenching and laying of 14,000 lineal feet of 51 in. diameter steel pipe, also the construction of a 4-span concrete bridge. The pumping plant will consist of three motor-driven centrifugal pumps, each having a capacity of twenty million Imperial gallons against a head of 280 feet. Tenders are being called for the above.

General Industrial

Hamilton, Ont.—Work has begun on the excavation for the factory of the T. Eaton Co., of Toronto.

Redcliff, Alta.—D. Broadfoot is endeavoring to make arrangements for the construction of an elevator here.

Collingwood, Ont.—The Bryan Mfg. Co. are asking a loan of $20,000 to assist in the building of a woodenware factory.

Latchford, Ont.—The Canadian Pulp & Lumber Co.'s mill has been destroyed by fire. The loss is estimated at about $50,000.

Aylmer, Que.—An option has been secured on 15 acres of land here for the erection of a sugar factory. D. A. Gordon, of the Dominion Sugar Co., Wallaceburg, Ont., is interested. It is understood that the plant will cost $400,000.

Vancouver, B. C.—H. T. Graham of Belleville, Ont. has purchased the Scottish-Canadian Cannery at Steveston. The plant will be renovated and new machinery installed for handling this season's catch.

Guelph, Ont.—An elevator will be installed at the gas works for unloading coal from the cars. It is also proposed to install a new gas holder next year. The Light and Heat Commission have the matter in hand.

Tenders

Ottawa, Ont.—Tenders on the supply of transformers, switches, and equipment will be received until August 3 by the chairman of the Waterworks Commission. Plans and specifications with the city engineer, R. L. Haycock.

Toronto, Ont. — Tenders will be received up to Tuesday, August 3rd, 1915, for the supply of—58 Tie Rods and Tie plates for Lansdowne Avenue Extension, Toronto Civic Railway. Specifications and forms of tender may be obtained at the Works Department, City Hall.

Winnipeg, Man.—Tenders will be received until Monday, July 26, 1915, for the supply of two 50-light, high efficiency incandescent Street Lighting Equipments, complete with lamps. Instructions to bidders, specifications and form of tender may be obtained at the office of the City Light and Power Department, 54 King Street.

Toronto, Ont.—Tenders will be received until Monday, July 26, 1915, for enlargement Manning Avenue School; new building Manual Training and Domestic Science Departments, King Edward School; iron fence, iron stairs, concrete floors, electrical work, local telephones, and midsummer repairs at sundry schools. Specifications may be seen and all information obtained at the office of the Superintendent of Buildings, City Hall, Toronto.

Oakville, Ont.—Tenders will be received by the chairman of the Oakville Water and Light Commission until Monday, July 26, 1915, for furnishing and installing one electrically-operated turbine pump of 600 Imperial gallons capacity against a head of 300 feet. Specifications may be seen at the office of the

Commissioners, Oakville, or at the office of Chipman & Power, engineers, Mail Building, Toronto.

Personal

A. F. Macallum, city engineer of Hamilton, Ont., has volunteered for active service.

Robert G. Allan, son of one of the founders of the Allan Line, and cousin of Sir Montague Allan, died in London, England, on July 15.

Lieut-Colonel Thomas Cantley has been elected president of the Nova Scotia Steel & Coal Co. He will also retain the position of general manager.

Joseph Austin Holmes, director of the Bureau of Mines Department of the Interior, Washington, D.C., died at Denver, Co., on July 13.

John Palmer, managing director of the Palmer-McClellan shoe factory of Fredericton, N. B., died on July 13, from paralysis. He was 64 years old and had twice been mayor of Fredericton.

J. J. Callaham of the Montreal and Southern Counties Railway, Montreal, Que., has been appointed operating manager of the London and Port Stanley Railway with headquarters at London, Ont.

Aubrey C. White, for over thirty years Deputy Minister in the Department of Lands, Forests and Mines, for the Province of Ontario and a very prominent free-mason, died on July 14 at his summer home in Muskoka, where he had gone for a rest. He was 69 years of age.

J. H. Sherrard, of Montreal, president of the Canadian Manufacturers' Association, is touring the west in furtherance of the project of forming an Exporters' Association to organize the export trade of Canada under the changed conditions caused by the war.

William T. Dunn, formerly tool steel expert for the Carpenter Steel Co. in Boston and New England, has been appointed by the International High Speed Steel Co. of New York district sales agent for New England and Eastern Canada. Mr. Dunn is at present taking a trip through the Cobalt and Porcupine district.

W. H. Westman, president of the Chatham, Ont., Board of Trade, has returned from a business trip to Chicago and points in the south in quest of new industries to locate factories in Chatham. Mr. Westman is in close touch with a number of companies on the other side that may later decide to locate Canadian branches.

Trade Gossip

The Hamilton Facing Mill Co., Hamilton, Ont., have increased their capital stock to $75,000.

Port Credit, Ont.—A Board of Trade has been formed here. W. C. C. Innes is the president.

The Beaver Asbestos Co., have changed their name to that of the Windsor Asbestos Co.

The Canadian Cartridge Co., Hamilton, Ont., has been authorized to increase its capital stock to $150,000.

Guelph, Ont.—It is announced that the Page-Hersey Iron and Tube Co. will resume operations at their plant here in a week or two.

The Rica-Wil Underground Pipe Covering Co., have obtained a license to manufacture pipes and pipe coverings in the Province of Ontario.

P. Lyall & Son Construction Co., Ltd. of Montreal, have obtained an extension of powers to permit them to engage in the manufacture of shells, guns and other munitions.

Montreal, Que.—The plant of the Montreal Technical School will be used for turning out certain lathe attachments and apparatus required for the manufacture of shells. A. Macheras is principal of the school.

The Polson Iron Works, Toronto, have applied to the City Architect's department for permission to make another small addition to their building for the purpose of manufacturing shells.

Catalogues

Gaskets—The Niagara Falls Gasket & Packing Co., Niagara Falls, Ont., has issued a leaflet dealing with their line of metal asbestos gaskets and the Ames alloy metallic sheet packing.

Steel Castings the product of foundries at Windsor, Ont., and Detroit, Mich., are illustrated and described in a catalogue recently issued by the Swedish Crucible Co. The special "Pyro" brand steel castings are included among the others, and in this connection are a few suggestions for successful carbonizing practice.

Frankfort Furnaces made by the strong, Carlisle & Hammond Co., Cleveland, Ohio. Catalogue No. 7 describes the various types of 'Frankfort' furnaces and states for what work each is specially adapted. Tables are included giving dimensions and other particulars for each size, while the concluding pages are devoted to various types of oil and gas burners, tanks, pyrometers, melting pots, etc.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Halifax, N.S.—T. Hogan & Co. will erect a machine shop here.

St. Jerome, Que.—Alfred A. Viau may establish a foundry here.

Brantford, Ont.—The Brantford Computing Scale Co. new factory is nearly completed.

Gondreau, Ont. — The Madoc Mining Co. will build a power house here at a cost of $70,000.

Port Hope, Ont.—The Standard Ideal Co. will probably receive an order for shells. H. T. Bush is general manager.

Charlottetown, P.E.I.—An effort is being made to obtain an order for shells for the Government railway shops here.

Fort Frances, Ont.—The town council will install a steam heating plant. Particulars may be obtained from C. E. Parry, town engineer.

St. Catharines, Ont. — Arrangements are pending for the extension of the Russell Jennings Co. factory to permit of their undertaking the manufacture of munitions.

Chatham, Ont.—At a special meeting of the City Council last Monday it was decided to turn over the Defiance Iron Works to Alex. Chaplin, of this city, for the purpose of manufacturing shells for the Dominion Government. The Defiance Iron Works is owned by the city.

Chatham, Ont.—The City Council recently received a letter from the Marskey & Schmidt Co., of Detroit, offering the city a contract for manufacturing a million shells as part of a ten million shell order which the company claims to have received from the Russian Government. This offer has been handed over to Alex. Chaplin.

Electrical

Otterville, Ont.—A hydro-electric system may be adopted by the town.

Harriston, Ont.—The hydro-electric by-law was carried here last Monday by a majority of 220.

Toronto, Ont.—An electric bell costing $1,400 will be installed on Eglington Avenue at a point where the G. T. R. and C. P. R. intersect.

St. Catharines, Ont.—The Hydro-Electric Commission are considering utilizing the spillways of the Welland Ship Canal for power purposes. This would be of considerable benefit to St. Catharines and district.

The Harrison Landry Mfg. Co., has been incorporated at Ottawa with a capital of $50,000 to carry on business as machinists and engineers, at Montreal, Que. Incorporators Andrew Harrison Landry and Michael Croghan of Montreal.

The Canadian Dadco Co. has been incorporated at Ottawa with a capital of $75,000 to manufacture mechanical metal devices of appliances for cranking and starting automobile or other gas engines at Toronto, Ont. Incorporators, John Cowan and John Thomas Fuller of Toronto.

Preference to Canadian Smelted.—The suggestion was made in the British House of Commons on July 20 by Sir Edward Cornwall that in the event of purchases of spelter being made in America there should be discrimination in favor of metal made in the United States from ores produced in British Columbia. The Ministry of Munitions promised to consider the suggestion.

Municipal

Delta, B.C.—The town will spend $20,000 on waterworks extensions.

Hull, Que.—The city council are in the market for a quantity of cast iron pipe and specials.

Winnipeg, Man.—Extensions will be made shortly to the high-pressure water main system.

Port Rowan, Ont.—The town council are considering the installing of an electric light plant.

Millardville, B.C.—The town council contemplate making extensions to the waterworks system.

Kamsack, Sask. — Additions will be made to the waterworks plant here to cost $35,000. H. H. Crawford is clerk.

Regina, Sask.—The city council has ordered additions to the waterworks plant to cost $44,500. George Beach is city clerk.

Galt, Ont.—A by-law will likely be submitted to the ratepayers to raise $20,000 for the improvement of the waterworks system.

Chambly, Que.—The town council will make extensions to the waterworks system. Motor-driven pumps and steel pipe will be required.

Chatham, Ont.—The town council have passed a by-law for the purchase of motor fire apparatus and truck, at an estimated cost of $13,000.

Canora, Sask.—The town council will install a waterworks plant to cost $17,700. The engineers are Chipman & Power, Toronto, Ont.

Toronto, Ont.—The Board of Control has recommended the purchase of two new electrically-operated pumps for the high-level pumping station.

Carlyle, Sask.—A by-law will be voted on by the ratepayers on August 9 to raise $3,000 for the purpose of completing the electric light and power plant.

Brockville, Ont.—The approval of the Provincial Board of Health is to be obtained re the laying of the proposed intake pipe before the by-law is passed.

Vernon, B.C.—The Municipal Council will build a new auxiliary pumping station to cost $3,000. One large pump and a 50-h.p. motor are required. D. G. Tate is city clerk.

The Pas, Man. — A light and power system will be installed here to cost $50,000. A waterworks and sewage system to cost $80,000 will also be installed. H. H. Elliott is clerk.

Toronto, Ont.—The recommendation of the Works Committee that tenders be invited for the construction of the proposed new duplicate waterworks system, estimated to cost $4,500,000, was rejected, and the matter was referred back for reconsideration.

Tenders

Ottawa, Ont.—Tenders on the supply of transformers, switches, and equipment will be received until August 3 by the chairman of the Waterworks Commission. Plans and specifications with the city engineer, R. L. Haycock.

Ottawa, Ont.—Tenders will be received until August 3 for high lift pumps and motors for the Lemieux Island pumping station. Plans and

If what you want is not advertised in this issue consult the Buyers' Directory at the back.

specifications may be obtained from the consulting engineer, S. B. MacRae, Ottawa.

Brighton, Ont. — Tenders will be received by the undersigned up to July 29, for the erection and completion of a foundry building at Brighton. Plans and specifications may be seen at the office of Geo. Drewry, Secretary of The D. J. Barker Foundry Co., Ltd., Brighton, Ont.

Toronto, Ont.—Tenders will be received up to Tuesday, August 3rd, 1915, for the supply of 58 tie rods and tie plates for Lansdowne Avenue Extension, Toronto Civic Railway. Specifications and forms of tender may be obtained at the Works Department, City Hall.

Ottawa, Ont.—Tenders for harbor and river improvements in the Mission River, Fort William, Ont., will be received at this office until Wednesday, August 4, 1915. Plans, specification and form of contract can be seen and forms of tender obtained at the Department of Public Works, Ottawa, and at the offices of the district engineers, Fort William, Ont.; Confederation Life Buildings, Toronto, Ont.; Shaughnessy Building, Montreal, P.Q.

Drumheller, Alta.—Tenders will be received up till Monday, August 16, 1915, for the following contracts: (1) Supply of about one mile of 6-in. and 4-in. steel or cast iron pipe; (2) valves and hydrants; (3) One return tube boiler and stack; (4) One duplex pump; (5) Materials for 30,000-gallon wood tank and housing; (6) All labor and certain materials for laying water mains, sinking an open well, constructing pumping station, and erecting wood tank and housing. Plans and specifications and other information may be obtained at the offices of the John Galt Engineering Co., Ltd., consulting engineers at Winnipeg and Calgary.

Contracts Awarded

Transcona, Man.—The Ideal Incinerator Co. of Toronto has been awarded a contract for an incinerator to cost $18,875.

Montreal, Que.—The City Council have awarded a contract for fire alarm boxes to the Northern Electric Co., Montreal.

Preston, Ont.—Wirsching Bros., have been awarded the contract for the foundation for the new Hurlbut shoe factory. No other contracts have as yet been let.

Orillia, Ont.—Thos. W. Stephens has been awarded the contract for the construction of the Orillia-Longford pole line by the Light and Power Commission. His tender was $1,250.

Toronto, Ont.—At a meeting of the Finance Committee of the Board of Education held recently contracts representing an expenditure of $30,512 were awarded. The chief amount was for $29,036 which is for the proposed new wing to be constructed to McMurrich Avenue School.

A. R. C. Clark & Son, St. John, N.B. have been awarded the contract for the installation of the water and sewerage system at Bathurst, N.B. The contract, which will amount to $131,000, covers the construction of a dam and pumping station and about seven miles of water and sewerage mains. A large standpipe with a capacity of 405,000 gallons will also be erected.

Assiniboia, Man.—The municipal council have awarded the following contracts in connection with the waterworks extensions: Canadian Iron Pipe Co., 500 tons iron pipe, $19,000; Western Steel & Iron Co., and Canadian Sarco Engineering Co., 130 hydrants, $5,000. All curved extras and special connections will be supplied by the Manitoba Bridge & Iron Works.

Trade Gossip

Edmonton, Alta.—The Edmonton Shell Co. has been incorporated with a capital stock of $50,000 to manufacture shells, explosives, guns, etc.

The Crown Furniture Co. has been licensed to carry on business in the Province of Ontario with a capital not exceeding $40,000. Austin Moss of Preston, Ont., is attorney.

Port Arthur, Ont.—The Western Dry Dock and Shipbuilding Co. is making good progress with the manufacture of its initial lot of farm tractors, plans for which were announced a few weeks ago.

The Goldie & McCulloch Co. of Galt, Ont., are prepared to manufacture fuse caps and such parts required for fixed ammunition except filling with powder. This concern has in operation a large forging and machining plant.

The Lake of the Woods Boat Co. has been granted a license with a capital stock of $80,000, and has appointed William J. Craig, Keewatin, Ont., its attorney. The company will manufacture boats, launches, engines and other equipment.

The Canadian Mill Supplies & Steam Specialties, Ltd., Toronto, Ont., has been incorporated with a capital stock of $40,000 to manufacture machinery and supplies for all industries. The provisional directors are Frank J. Hughes, Thomas B. Smyth and Duncan P. Clark, all of Toronto.

Iroquois Falls, Ont.—The first run of paper from the large Abitibi pulp and paper mill was made last week. Only one unit is running at present, but this will be augmented by two others which are being put up and adjusted. The mill, which is the largest in Canada, will, it is expected, be running full by September.

Semi-finished Steel Short of the Demand.—It is reported from Pittsburgh, Pa., that for the first time in two years manufacturers report a scarcity of semi-finished steel. Pittsburgh producers of open-hearth steel billets and sheet bars have been out of the market, so far as new business is concerned, for some time, but the pressure for delivery on orders booked has been so great that shipments are behind. Youngstown steel makers yesterday advanced the price of sheet bars to $23.50, Pittsburgh, the highest point in more than two years. A month ago sheet bars were available at $20.50, Pittsburgh.

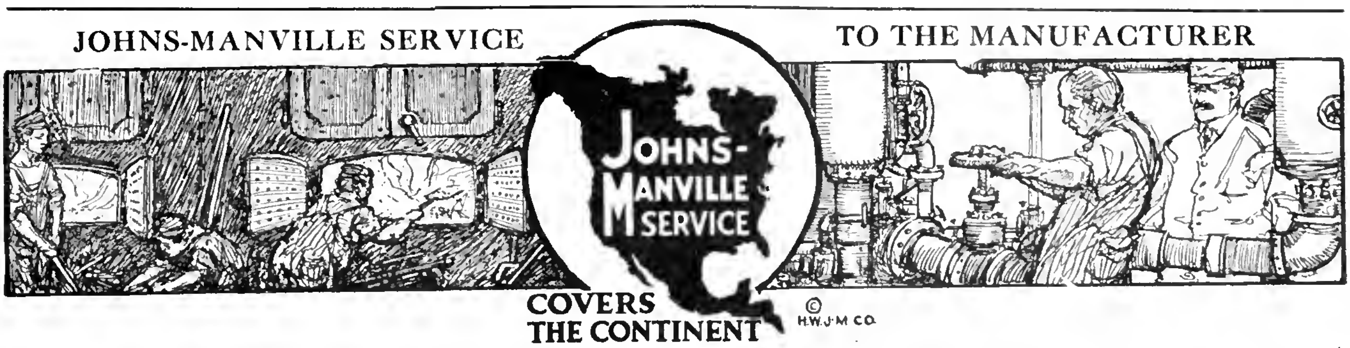
David A. Thomas at Ottawa.—D. A. Thomas, who represents Lloyd George, British Minister of Munitions, in America, arrived in Ottawa on July 25. He is accompanied by Gen. R. H. Mahon and R. H. Carr, and will remain there for some time in close touch with the Canadian Shell Committee. The party will also visit Montreal, Toronto and other cities. Although Mr. Thomas has been given wide powers by the British Minister of Munitions, he states it is not his intention to buy munitions in Canada. The Canadian Shell Committee will attend to that. What his mission is is to inquire into the capacity of the Dominion to turn out shells, rifles, small arms ammunition and explosives.

Personal

A. M. Bray, assistant professor of electrical engineering at McGill University, Montreal, has resigned to become professor of electrical engineering at Cornell University.

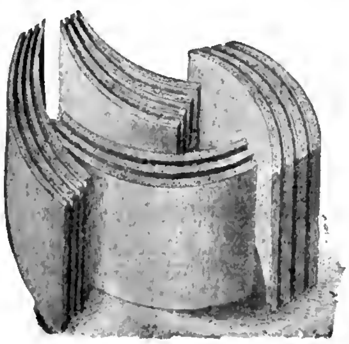
Warren Chambers resigned his position as superintendent with the Chapman Double Ball Bearing Co., Toronto, recently. He has joined the Cobourg Steel Co., which secured a shell contract some time ago.

W. J. McCallum, until recently chief draftsman with the Chapman Double Ball Bearing Co., Ltd., Toronto, has assumed the position of superintendent,



THIS emblem is more than a trade-mark device. It stands for the experience, ability and business integrity of a long-established house. So that any article upon which it appears is not merely offered for sale; it is meant to give service. And that every J-M Product shall give this service fully and permanently, is the whole meaning of J-M Responsibility.

The most important thing about a stack is the draft area. Why choke it up with a thick fire-brick stack lining?



J-M Vitribestos Stack Lining offers even greater lining protection than fire brick, and weighs about 1/10 as much. A six-foot stack lined with J-M Vitribestos allows a net draft diameter of 5′ 8″ and gives maximum draft area.

If you are figuring a new stack, order a lighter gauge material—a lighter foundation and a J-M Vitribestos Lining. You'll have a better stack and a cheaper one.

Vitribestos Stack Lining is impervious to all effects of smoke and fumes of combustion.

It has been a revelation to users. Are you interested in revelations that save money?

Be sure of these three things in planning your pipe covering installation

(1) Proper design of covering.
(2) Good quality of covering.
(3) Proper application of covering.

These things are all of great and equal importance. You may buy a good covering and pay a fair price for it, but it may not be the covering for your conditions. You may buy a good-looking covering and have it fail on account of its inefficiency, and again the best covering obtainable may be inadequate as a heat insulator if not properly applied.

Johns-Manville Pipe Covering Service satisfies these three conditions of Design, Quality and Installation. This service includes advisory work in planning the job, it includes the *right* covering, of insured quality, and, if you please, it includes the proper installation of same through the contract departments of its branches.

If you prefer to apply these coverings yourself you will appreciate the convenience of materials that go on and come off easily and quickly without breakage or mutilation.

Johns-Manville Pipe Covering Service starts with the plan and stays with the job to the finish.

One Style of J-M Heat Insulation

rendered vacant by the resignation of Warren Chambers.

H. E. Tanner, formerly assistant town engineer of Chicoutimi, Que., and for three years on the engineering staff of the Transcontinental Railway, has been appointed to succeed Mr. H. Hadley as city engineer of Verdun, Que.

J. Frank Chapman, general manager of the Thousand Islands Railway and the Oshawa Railway, passed away recently at his residence in Gananoque. Ont. The deceased, who was a railroad man of thirty-four years experience, was born in Frankford, Ont., in 1863.

Hurlbut S. Jacoby, formerly chief engineer of the Standard Steel Construction Co., of Welland, Ont., and recently appointed Instructor in Civil Engineering at Pennsylvania State College, has been retained as associate engineer for summer work by the Samuel Austin & Son Co., industrial engineers and builders, of Cleveland, Ohio.

Clark T. Morse, formerly Montreal and Toronto district manager for the Canadian Sirocco Co., has been transferred to the head office at Windsor, Ont., to take charge of the engineering and sales work in place of Ralph T. Coe, resigned. A. M. Nichol continues in charge of Eastern Canadian sales with headquarters in McGill Bldg., Montreal.

Ralph T. Coe, manager of the Canadian Sirocco Co., Windsor, Ont., since the organization of the company, has resigned to enter the engineering service and sales field in New York State. Mr. Coe has been appointed district manager for Warren, Webster & Co. and the American Blower Co., and will have offices at 519 Insurance Bldg., Rochester and 19 Live Stock Exchange Bldg., Buffalo, N.Y.

Sir Sandford Fleming, engineer and scientist, died at Halifax on July 22, after a short illness, at the age of 88. Sir Sandford was known as the dean of the engineering profession in Canada and the "father of the Canadian Pacific Railway." Sandford Fleming was born in Kirkealdy, Fifeshire, Scotland, on January 7, 1827. He was educated there, and came to Canada in 1845. He joined the engineering staff of the Northern Railway, Toronto, subsequently becoming chief engineer. Later he practised engineering in Ontario, and was elected a member of the Institute of Civil Engineers, London, and of the American Society of Engineers, and elected honorary member of the Canadian Society of Civil Engineers. In 1863 he was chosen by the Governments of Canada, Nova Scotia and New Brunswick and Great Britain to conduct a survey for the first link of a railway which would join the Atlantic and the Pacific. His survey showed the practicability of the scheme, which developed, when carried out, into the Canadian Pacific Railway system. He helped to build the railway system of Newfoundland. In recognition of his public services Queen Victoria made him a Companion of the Order of St. Michael and St. George in 1877 and a Knight Commander in 1897.

Wood-Working

Smithville, Ont.—The sawmill of Robert E. Brooks has been destroyed by fire, with a loss of $5,000.

Tenino, B.C.—The plant of the Tenino Lumber Co. has been totally destroyed by fire with a loss of $60,000.

Montreal, Que. — Z. Charbonneau's sash and door factory on Alice street has been destroyed by fire with a loss of $20,000.

Newcastle, N.B.—W. M. Sullivan's mill at Redbank has been destroyed by fire. The loss is estimated at about $40,000.

Monteith, New Ont.—C. Brisbois will build a sawmill and pulp mill here. John Thompson, Peterborough, Ont., is interested in the undertaking.

West Broughton, Que.—T. Beaudouin's saw mill which was totally destroyed by fire with a loss of $8,000, will be rebuilt. Steam power machinery is required.

Goderich, Ont.—A furniture factory is being erected here for J. E. Baechler, Goderich Lumber & Milling Co., who is in the market for wood-working machinery.

North Bay, Ont.—The loss by fire of the Gordon Lumber Co. saw mill at Cache Bay on July 19 amounted to $150,000, of which $75,000 is covered by insurance.

Ottawa, Ont.—The Davidson Woodworking Factory will build a large addition to its plant. Woodworking machinery will be required. L. Henderson is manager.

Haileybury, Ont.—The Dunbar Lumber Co. mill was entirely destroyed by fire on July 13. The loss is estimated at $15,000, of which about $4,500 is covered by insurance.

St. John, N.B.—Fire completely destroyed the Miramichi Pulp Mill property at Chatham, N.B. Only the office building remains. The loss is estimated at $50,000, and is partly covered by insurance.

Berwick, N.S.—Berwick Planing Mills, owned by J. W. Hutchinson, were destroyed by fire on July 14. The loss is over $10,000. In addition to the machinery much valuable lumber was destroyed. There was no insurance.

Building Notes

Beamsville, Ont.—The Board of Education contemplate erecting a school at an estimated cost of $20,000.

Orillia, Ont.—The town council have decided to build a new town hall to replace the building recently destroyed by fire.

Transcona, Man.—It is proposed to build a new school at a cost of $35,000. A by-law will be submitted to the ratepayers.

Winnipeg, Man.—A permit has been granted to build a school at St. Boniface to cost $139,544. The building will be 156 feet x 83 feet and three stories high.

Regina, Sask.—The Robert Simpson Co. of Toronto will erect a building here in connection with their mail order business. The cost is estimated at $150,000.

Chatham, Ont.—The McClary block on King street, recently destroyed by fire, will be rebuilt. A permit has been issued for the work, which it is estimated will cost $10,000.

Levis, Que.—Work is being actively pushed ahead on the construction of the

new Intercolonial freight shed here. The new freight shed is to be 400 x 50 feet, built of concrete, brick and structural steel, and will be thoroughly fire-proof and modern in every detail. The work is in the hands of Mr. G. B. Mitchell, contractor, of Montreal.

General Industrial

Collingwood, Ont.—A by-law will be voted on by the ratepayers on August 11 to grant a loan of $20,000 to the Bryan Manufacturing Co.

Selkirk, Man.—J. S. Hughes, Mill Village, N.S., is interested in a company which will construct a pulp and paper mill at Selkirk, Man., to cost $150,000.

Aurora, Ont.—A syndicate has been formed to establish a plant here for making mechanical orchestras. The Ontario Realty Co., 35 Yonge street, Toronto, are interested.

Railways-Bridges

Alexandria, Ont.—The G. T. R. station here has been completely destroyed by fire.

London, Ont.—The London and Port Stanley Railway was officially opened, by Sir Adam Beck on July 22.

Oil-burning Locos. on G.T.P.—Morley Donaldson, vice-president of the Grand Trunk Pacific Railway, announces that the installation of oil-burning locomotives on the mountain section of the lines has now been completed. These locomotives are of the most modern type and were placed in service for passenger traffic for the first time on July 24. They are operating from Jasper to Prince Rupert, over 719 miles of main line. Especial interest attaches to the installation of this class of motive power, as it marks the first use of oil-burners on an extensive scale in Canada. Oil storage tanks have been erected at various points for supplying locomotives with the necessary fuel.

New Incorporations

The Alton Foundry Co. has been incorporated with a capital of $50,000 to carry on business at Alton, Ont. Incorporators: J. M. Dods, E. Dods and T. B. Deagle, all of Alton, Ont.

The Canadian Ventilator Co. has been incorporated at Ottawa with a capital of $50,000 to manufacture ventilators, screens, etc., at Ottawa. Arthur Ellis, Robert A. Devine and Howard Murray, all of Ottawa, Ont., incorporators.

Classified Advertisements

¶ Those who wish to sell or buy a business, obtain competent help, connect with satisfactory positions, or secure aid in starting new enterprises, should not fail to use the Want Ad. Page of "CANADIAN MACHINERY."

WANTED — EQUIPMENT FOR MACHINE (repair) shop; weight or accuracy not important as price. Give full details. Box 153, Canadian Machinery. (8)

The Lachine Manufacturing Co., has been incorporated at Ottawa with a capital of $120,000 to manufacture bombs and other munitions of war at Lachine, Que. Incorporators—Joseph Descarries and Theophile N. Descarries, of Lachine.

The W. J. Trick Co. has been incorporated at Toronto with a capital of $250,000 to manufacture interior fittings and all kinds of woodwork at Oshawa, Ont. Incorporators: John Fraser Macgregor and Thomas Stewart Hagan Giles, of Toronto.

The Waterproof Stockings, Ltd., has been incorporated at Toronto with a capital of $50,000 to manufacture rubber goods and dry goods of all kinds at Toronto. Incorporators: Frederick Charles Stewart and George Alfred Stewart of Toronto.

The Architectural Woodworking Co. has been incorporated at Ottawa with a capital of $50,000 to manufacture all kinds of office equipment, store fixtures and revolving doors, etc., at Toronto, Ont. William A. Riddell and Harvey Obee, of Toronto.

The Canadian Mills Supplies & Steam Specialties, Ltd., has been incorporated at Ottawa with a capital of $40,000 to manufacture machinery and supplies for all industries at Toronto, Ont. Incorporators, Frank Joseph Hughes, Daniel Kelly, of Toronto.

The St. Thomas Construction Co. has been incorporated at Ottawa with a capital of $40,000 to manufacture shrapnel and high explosive shells at St. Thomas, Ont. Incorporators: Albert Edward Ponsford and Edward Austin Horton of St. Thomas, Ont.

Dominion Aluminum Last Co. has been incorporated at Ottawa with a capital of $50,000 to manufacture boot and shoe lasts, etc., at Windsor, Ont. George A. Farabaugh, William H. Holland and George Chester Clarke, all of South Bend, Ind., incorporators.

The Boving Hydraulic and Engineering Co. has been incorporated at Ottawa with a capital of $500,000 to carry on business as mechanical, hydraulic engineers and contractors at Lindsay, Ont. Donald McLean, James Boxall and William Flavelle, all of Lindsay, Ont., are the incorporators.

Refrigeration

Halifax, N.S.—The City Council have appointed a committee to look into the question of establishing a municipal abattoir. It is estimated that it will cost about $70,000.

The Anglo American Pork Products Co. has been incorporated at Ottawa,

with a capital of $5,000, to manufacture and refine oils, greases, paint and oil products, etc., at Toronto. Incorporators: Harry Riley and Alfred Bicknell, of Toronto.

Marine

Midland, Ont.—The new locks at Port Severn were officially opened on July 26. This point is the Georgian Bay end of the Trent canal.

Kingston, Ont.—After being in commission for 25 years or more, the Dominion Public Works dredge 105 is to be placed on the scrap heap at Ottawa. For the past 8 months this dredge has been engaged deepening the harbor at Bowmanville.

St. John's, Nfld.—The purchase by the Russian Government of the ice-breaking steamer Bruce from the Reid Newfoundland Co. is announced. It is understood that the Bruce, with her sister ship, Lintrose, bought by Russia last winter, will be used in the White Sea during the fall and winter in an effort to keep open later than usual the channel to the port of Archangel. The Bruce and the Lintrose were built a few years ago for service in Cabot Strait, between Newfoundland and Cape Breton, where heavy ice is encountered in the winter. They are steamers of 1,553 tons.

Too Big for Canal.—William G. Davidson, president of the Staten Island Shipbuilding Co., has just purchased four of the large vessels of the Erie Railroads Lake Line, the Brownell, Underwood, Binghampton and Oswego. President F. D. Underwood of the Erie Railroad has made announcement of the sale. The big vessels are too large to go through the Welland Canal, so they will be cut in two and towed through in that manner. The cutting will be done in Buffalo, and the approximate cost of the cutting, towing and insurance will be $25,000. The boats will be used in the coastwise and trans-Atlantic trade.

Catalogues

Grinding and Polishing Machines made by J. G. Blount Co., Everett, Mass. A new catalogue, No. 17, describes at length a complete line of grinding and polishing machinery and speed lathes. Specifications giving the principal dimensions of each type of machine are included and numerous illustrations show the distinctive features embodied in the design of the various types. Copies may be had on application.

Marine Engines.—Catalogue No. 11, issued by the Gas Engine & Power Co., and Charles L. Seabury & Co., Consolidated, New York City, describes the Seabury marine engines for commercial and pleasure craft. A description covering the design of this type of engine is given accompanied by a number of illustrations. A list of the various sizes is included giving the principal dimensions for various horse powers.

Centrifugal Pumps is the title of a 64-page bulletin just issued by the Terry Steam Turbine Co., Hartford, Conn., giving details and data on various turbo-pump applications. The principles of operation and construction of the centrifugal pump are clearly explained, as are the details of the steam turbines which have been successfully used during the past ten years for driving them. This booklet should be in the hands of those who are interested in any kind of a pumping problem. Copies may be obtained on application.

Steel Poles for telephone, telegraph, trolley and transmission lines, etc., is the subject matter of a new catalogue issued by the Carbo Steel Post Co., Chicago, Ill. The "Carbo" steel pole is featured and the principles involved in their design, adaptability, durability and construction. A detailed comparison is made between "Carbo" steel and wooden poles for transmission lines as regards cost of installing, length of service, etc.

Steam Traps.—The Morehead Mfg. Co., Detroit, Mich., have issued catalogue No. 11, dealing with the "Morehead" tilting steam traps and comprising a description of the Morehead "Back to Boiler System" of steam drainage and boiler feeding. The catalogue contains 64 pages and the matter is well arranged. The construction and operation of the various types of steam traps are fully described and illustrated and their principal features dealt with at length. Numerous illustrations are given of plants with the traps installed as part of the "Morehead" system, and showing the wide and varied application of these traps. The illustrations are accompanied by brief descriptions stating the type of trap installed and the kind of plant.

Wagon and Truck Loaders.—The Link-Belt Co., Chicago, Ill., are distributing their new portable wagon loader catalogue No. 210, which describes the machine claimed to load a wagon or truck with material carried on the ground at the rate of one ton per minute. Specifications and price lists are given for each type of machine and numerous illustrations show the wide range of work and various materials these loaders are capable of handling. A number of tes-

timonials and partial list of users are also included.

Slotting Machines.—The Newton Machine Tool Works, Philadelphia, Pa., present their new catalogue, No. 49, dealing with a complete line of standard and special slotters. Specifications giving the principal dimensions of each type are included, accompanied by illustrations. These latter also show machines driven by belt, the pneumatic clutch and reversible motor, in addition to the crank and screw driven machines. A further series of illustrations in the form of an insert show many designs of milling, boring, drilling, and cold saw cutting-off machines.

Steel Split Pulleys.—An attractive catalogue issued by the Keystone Pulley Co., Oneida, N.Y., contains particulars covering the "Keystone" steel split pulleys. The principal features incorporated in the design of these pulleys are described in detail and the illustrations give a good general idea of their construction. Price lists and shipping weights are given for each size and the illustrations show the various types of pulley and also interior views of the factory where they are made. The catalogue concludes with some useful rules for finding pulley diameters and speeds.

Lagonda Vibrator Cleaners is the name of the latest catalogue of the Lagonda Manufacturing Co., Springfield, Ohio. This bulletin discusses formation and removal of scale from fire tube boilers, and describes and illustrates the new Lagonda Vibrator Cleaner, which is proving most highly effective in removing scale from fire tubes. The cleaner also loosens the soot on the interior of the tubes and it is blown out by the air or steam exhausting from the front end of the turbine. The turbine used in this cleaner is the Lagonda high efficiency, high power, air or steam driven machine. Copy of this bulletin will be sent to anyone on request.

Centrifugal Blowers and Compressors for all pressures from 5 ins. of water, as in mechanical draft service, up to 125 lbs. per square inch, as for compressed air distribution in mines, machine shops, ship yards, etc., are described in a 64-page book issued by the DeLaval Steam Turbine Co., of Trenton, N.J. The development of the high efficiency, high-speed centrifugal blower or compressor has been conditional upon improvements in materials, construction, shop practice and design such as are employed in the building of high-grade steam turbines. By careful calculation of stresses, and by the use of good materials and workmanship, it is possible to run blower and compressor wheels safely and satisfactorily at peripheral velocities of 450 to 600 ft. per second, which makes it pos-

sible to develop as much as 3 or 4 lbs. per square inch pressure in a single-stage blower. In the present publication numerous charts are given showing curves for the isothermal, adiabatic and actual compression of air, also the theoretical power required to compress air and characteristic curves of single—and multi-stage blowers and compressors. The influence of impeller design upon the form of the characteristic is discussed at some length. Particulars are given concerning the application of centrifugal blowers and compressors to forced draft, coal gas manufacture, coke oven plants and water-gas plants, sugar factories, cupola and blast furnace work, Bessemer converters, supplying compressed air in mines, ship yards, etc. The illustrations present numerous examples of blowers and compressors directly connected to steam turbines and to electric motors.

Book Reviews

A Study of Boiler Losses, by A. P. Kratz, has been issued as Bulletin No. 78 of the Engineering Experiment Station of the University of Illinois. This bulletin presents a critical analysis of the data obtained from a series of twenty-five trials made on a 500 horse-power Babcock and Wilcox boiler located in the heating plant of the University. The boiler was operated under varying conditions of load and depth of fuel bed. Curves are presented and conclusions are drawn regarding the conditions necessary in order to secure the best continuous operation. In these tests, gas samples were taken both at the bridge and in the breeching, and a determination of the loss due to air leaking through the setting was made. A curve is also given which shows the percentage of excess air represented by the different amounts of CO_2 appearing in the gas. The heat balance has been subdivided so as to isolate and determine the amount of the several losses chargeable to the boiler, furnace and setting. Complete forms for calculating a series of boiler trials are given, and the corrections for differences in pressure and water levels at the beginning and end of a test are discussed. Tests were also made using some samples of coal which had been exposed to the weather for about six years. An interesting fact brought out was that no difficulty was experienced in burning the weathered coal. It had deteriorated until it was of about the same composition and grade as the fresh Vermilion County screenings, and its steaming qualities compared very favorably with those of the latter. Copies of Bulletin No. 78 may be obtained gratis upon application to C. R. Richards, Acting Director of the Engineering Experiment Station, University of Illinois, Urbana, Ill.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Niagara Falls, Ont.—Fire did $1,000 damage to the melting room of the Pollard Mfg. Co. foundry.

Toronto, Ont.—The Canada Metal Co. are making extensions to their factory at a cost of $15,000.

St. Catharines, Ont.—The McKinnon Dash & Metal Works will start the construction of an addition.

Calgary, Alta—The Canadian Pacific Railway is increasing its shell-making facilities at the shops here.

Welland, Ont.—The Canadian Billings & Spencer Co. will purchase forge and metal-working machinery to cost $30,000.

Truro, N.S—The Truro Engineering Co. will install $27,000 worth of machinery in its plant for the manufacture of shells.

Port Arthur, Ont.—The Western Dry Dock & Shipbuilding Co. has received a new order for a large number of high explosive eighteen-pound shells.

Calgary, Alta.—DuCane, Dutcher & Co., consulting engineers, of Vancouver, B.C., are working on a hydro-electric power project on the Elbow river near here.

St. Thomas, Ont.—The St. Thomas Construction Co., who have taken over the Steel Vault Co. plant in order to make shells, are in the market for machinery for this purpose.

Montreal, Que—The Aetna Chemical Co., will build a plant at Drummondville, Que. The general contract has been awarded to the Westinghouse, Church, Kerr & Co., Montreal.

Toronto, Ont.—A building permit has been issued to the Polson Iron Works for the erection of a one-storey frame and metal addition to their factory on the Esplanade, costing $3,000.

St. Catharines, Ont.—Work will be started at once on the construction of an addition to the factory of the Whitman & Barnes Mfg. Co. The new structure will enlarge the forge room to double its present size.

Stratford, Ont.—R. C. Bartlett has secured the Morelock factory building and will install machinery and equipment for the manufacture of automobiles. Mr. Bartlett has been manufacturing automobiles in Toronto, Ont., for some time.

Hamilton, Ont.—The Canadian Cartridge Co. will spend $150,000 on machinery to be installed in its plant which is being erected here. A main building, to cost $30,000, and a boiler house and machine shop will be constructed first. The total investment will be $250,000.

Ford, Ont.—Work on another new addition to the plant of the Ford Motor Co., at an estimated cost of $60,000, has been started. It will extend for 705 feet along the Detroit River frontage. The building will be one storey high, of concrete with a steel "saw tooth" roof. It will be devoted entirely to machine shop work.

Quebec, Que.—G. B. Mitchell, of Montreal, has just been granted a sub-contract by M. P. & J. T. Davis, the contractors of the Lauzon Dry Dock, for the construction of the new power house for the latter. The power house will be 120 x 100 feet, of brick and steel. The smoke stack will be of brick, 180 feet high, 20 feet in circumference at the base and 14 feet at the top. The pump house will be 50 x 70 feet.

Electrical

Blenheim, Ont.—Work will start shortly on the construction of the sub-station in connection with the hydro-electric system.

Municipal

Colborne, Ont.—The town council will buy a fire engine. The by-law has passed.

Melfort, Ont.—The town will spend $2,500 on extensions to the telephone system.

Matheson, Ont.—The town will spend $20,000 on the construction of a waterworks system.

Outremont, Que.—The City Council have decided to buy a combined sprinkler and flushing machine.

Palmerston, Ont.—A by-law providing for the installation of a hydro-electric system will be submitted to the ratepayers on August 7th.

Meaford, Ont.—A by-law will be voted on by the ratepayers on Aug. 16 to authorize the expenditure of $4,000 on waterworks extensions.

Milverton, Ont.—By a majority of 155—only seven ratepayers voting against the measure—Milverton carried a hydro-electric by-law on July 30.

Carlyle, Sask.—A by-law will be voted on by the ratepayers on Aug. 9 for the purpose of raising $3,000 to complete the civic power plant.

Lennoxville, Que.—A by-law has been passed authorizing the purchase of the waterworks, and the expenditure of $14,000 on repairs and extensions.

London, Ont.—It is proposed to spend $62,000 on electric light plant and $30,000 on waterworks extensions. A by-law will be submitted to the ratepayers.

Markham, Ont.—It is estimated that the proposed extensions to the waterworks system will cost $15,000. E. A. James, Adelaide street, Toronto, is the engineer.

Montreal, Que.—It is expected that a retaining wall will have to be built to protect the aqueduct. The length of wall will be about seven miles and the cost approximately one million dollars.

Brockville, Ont. — Dr. McCullough, chief medical officer of health for Ontario, has written the chairman of the Board of Water and Light Commission approving of the location of the proposed new intake pipe at the pumping station. To ensure a pure water supply, Dr. McCullough insists upon the installation of a filtration plant.

General Industrial

Galt, Ont.—Getty & Scott, Ltd., propose making an extension to their factory.

Calgary, Alta.—The Southern Alberta Refineries, Ltd., will establish a refinery near here.

Louisburgh, N. S.—The Marconi Wireless Telegraph Co. will make extensive alterations and additions to its plant.

Chatham, N. B.—The Miramichi pulp mill of the Dominion Pulp Co was de-

stroyed by fire recently with a loss of $50,000.

Calgary, Alta.—The Western Canada Flour Mills Co. have started construction work on five of its ten new elevator plants to be built at once in Alberta. The five points at which work is now progressing are, Ensign, Kircaldy, Champion, Dalmead and Street, Alberta, and five more points, yet to be chosen, will each get one of the new elevators. The new elevators will be built at a cost of $75,000.

Tenders

Regina, Sask.—Tenders will be received by the City Commissioners up till Monday, September 6th, 1915, for the supply, delivery and erection of a 7,000,000 gallon pumping unit at the city power house. Specifications and other information may be obtained from J. M. MacKay, Superintendent of waterworks, Regina, Sask.

Contracts Awarded

Strathroy, Ont.—The Nicholson Planing Mills have received an order for shell boxes.

Lachine, Que.—The city council has awarded the contracts for the supply of cast-iron water pipe to the Dominion Bridge Co.

Windsor, Ont. — The city council awarded the contract for the supply of cast iron water pipe to the National Iron Works, Ltd., Toronto, at $30.25 per ton, and for specials, valves, hydrants, etc., to the Kerr Engine Works, Walkerville, Ont.

Building Notes

Barrie, Ont.—Work will commence at once on a new $15,000 Carnegie Library.

Toronto, Ont.—The city architect's department has issued a building permit to Gunn's Limited for the erection of a two-storey corrugated iron warehouse, costing $6,000, on Symes road, near Scarlett road.

Toronto, Ont.—A building permit was this morning issued to the Dunlop Tire & Rubber Goods Co., for the erection on Booth avenue near Queen street of a three-storey brick addition to their factory costing $30,000.

Railways-Bridges

Toronto, Ont.—Plans for the construction of the new pedestrian subway under the tracks at Ashdale Avenue will shortly be submitted to the Dominion Railway Board for approval. The estimated cost is $11,500.

Fredericton, N.B.—Premier Clarke has announced that borings would be made for the proposed bridge crossing for the St. John Valley Railway at Gorham's Bluff, near the Mistake. This work is to start as soon as arrangements can be made to have the drilling outfit taken to Gorham's Bluff and will be rushed to completion. Premier Clarke stated that this course had been finally decided upon by the government.

Wood-Working

Martintown, Ont.—A. D. Clinger's sawmill has been destroyed by fire. The loss is estimated at $8,000.

Ditchfield, Que.—Fire recently destroyed the saw mill belonging to P. H. Renaud. Loss is estimated at $6,000, which is covered by insurance.

Marine

Kingston, Ont.—Navigation on the Rideau is practically at a standstill. All season the steamer Rideau Queen has been unable to proceed as far as Smith's Falls, owing to low water. On July 27, the steamer was taken off the route entirely. Lately she has been able to go only as far as Portland.

S.S. Parima Damaged.—The freighter Parima, of the Quebec Steamship Co., was damaged by fire on July 29, at Hoboken, N.J., where the ship was undergoing repairs. The fire is believed to have started in a pile of rubbish collected for removal. An investigation is being made to determine whether the blaze was of accidental or incendiary origin.

Refrigeration

Ingersoll, Ont.—A large cold storage plant and tin shop will be constructed by the Borden Milk Co.

Personal

J. T. Breckon, waterworks engineer for the city of Vancouver, B.C., has resigned.

R. H. Parsons, superintendent of the municipal power plant at Edmonton, Alta., has resigned.

M. S. Gibson has been appointed general manager of the National Fireproofing Co. of Canada, Ltd., with headquarters at Toronto.

Hon. Jean Provost, ex-Premier of Colonization, Mines and Fisheries in the Gouin Government, and member of the Legislature for Terrebonne, died at Quebec on July 26, in his forty-sixth year.

M. J. Butler, C.M.G., of Armstrong, Whitworth of Canada, Ltd., is to be appointed consulting engineer of the Montreal city waterworks, which will include the construction of the filtration plant and the widening of the aqueduct.

Joseph R. Henderson, of Montreal, president and general manager of Brandram-Henderson, Ltd., Montreal and Halifax, manufacturers of paints, etc., died suddenly in Halifax on July 31. He was born in Hexham, Northumberland, England, in August, 1851. He will be buried in Halifax.

Trade Gossip

Vancouver, B.C.—It is reported that the plant of the Ocean Falls Co. will be re-opened.

The Cedars Rapids Manufacturing & Power Co., have under consideration adding 10,000 to 30,000 horse power to the capacity of the plant.

The General Car & Machinery Works, Ltd., of Montmagny, P.Q., makers of road machinery, have opened an office at 317 St. James street, Montreal, under the managership of J. H. Langis.

Canadian Shipping. — During 1914 there were constructed in Canada 43,346 tons of new shipping, which at $30 per ton, as a fair average value, makes the total value of vessels entered on the Canadian registry $27,972,000. The tonnage constructed in 1914 is the largest annual output of the Dominion in 15 years.

Scarcity of Coal Freighters.—The Sydney Record says that owing to scarcity of ships, it understands that negotiations are in progress between the Dominion Coal Co. and the Intercolonial Railway for the shipment of a large tonnage of coal from Sydney to Quebec and Montreal by rail. Owing to a quietness in freight business, it is considered possible an arrangement will be concluded at a tariff profitable to the railway and satisfactory to the Coal Co.

Aetna Explosives Co.—The big plant of the Aetna Explosives Company, upon which operations are being rushed at Drummondville, Que., will stand as one of the important industries which the war business has brought to Canada. A subsidiary of the Aetna Explosives Co. of the United States, it will be backed entirely by American capital, but the

HANG THIS UP

There is a Geometric Die Head on every make of screw machine engaged in thread cutting.

Some day we will ask you to strike out the word "make," for it is our purpose to put a Geometric Die Head on every screw machine engaged in thread cutting.

Every condition fosters this expectation :—

Die Heads that are indispensable to those who have used them.

Expert workmen.

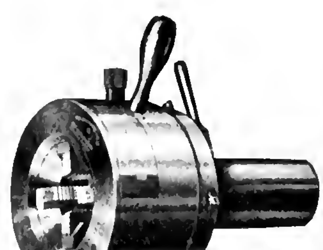
Business integrity.

A reputation that is sound.

A strong faith in The Geometric Tool Company, its products and its customers.

DO YOU KNOW WHAT GEOMETRIC SATISFACTION IS?

You probably do not know how satisfied you can be with your Screw Threading Operations unless you know what Geometric Satisfaction is.



Ask us about it in connection with your requirements.

THE GEOMETRIC TOOL CO., NEW HAVEN, CONN., U. S. A.

Canadian Agents:—Williams & Wilson, Ltd., Montreal; The A. R. Williams Mchy. Co., Ltd., Toronto, Winnipeg, St. John, N.B.

business for the time being at least will be the outcome of the big contract which the company secured from the Canadian Car & Foundry Co. to supply explosives in connection with the Russian shell order. The company has secured a big site outside the town of Drummondville, and the plant will probably cost $500,000 and employ a large number of hands. The operation of the works is expected to commence in the course of a few months to fill contracts this fall.

Catalogues

The Universal Iron & Supply Co., St. Louis, Mo., have issued a leaflet giving particulars of storage tanks with sketches of various types. An interesting feature is a calibration curve for horizontal cylindrical tanks of any dimensions.

The Providence Engineering Works, Providence, R.I., have mailed a bulletin describing the "Providence" shaper which they are putting on the market. The essential features incorporated in the design of this machine are dealt with, and a brief specification is included giving the principal dimensions. Two illustrations give a general idea of the style of machine.

The Sunbeam Index to the proper lighting of homes is the title of a bulletin issued by the Canadian General Electric Co., Toronto. The bulletin contains much useful information on the illumination of the various parts of a house accompanied by a table on the selection of the right lamp. Another table gives the cost of electricity for the various electrical devices used around the home.

Pulleys—The Oneida Steel Pulley Co., Oneida, N.Y., have issued a new general catalogue No. 5 dealing with a complete line of pulleys of both steel and wood construction. The principal features embodied in the design of these pulleys are described in detail with explanatory illustrations. Price lists are included and also tables giving weights of stock sizes and a telegraph code. The catalogue concludes with a number of mechanical tables.

Electric Furnaces made by the Canadian Hoskins, Ltd., Walkerville, Ont., are described in bulletin No. 12. Full particulars are given covering the construction, temperatures, operation and uses of furnaces, together with dimensions and price of each size. Other lines dealt with include thermo-electric pyrometers, portable and wall meters, etc. Inserted leaflets illustrate and describe the "Stewart" combination furnace,

gas and oil furnaces and a recalescent outfit. The catalogue is fully illustrated.

Power Transmission Appliances. — The "Keystone" line of improved appliances for power transmission is the subject of introductory bulletin K2 issued by the Keystone Pulley Co., Oneida, N.Y. The line dealt with in this bulletin consists principally of various types of shaft hangers and pillow blocks, but safety set collars, flange and clutch couplings are also included. The principal features of these products are clearly explained accompanied by illustrations and diagrams. Several tables give dimensions and prices for each size.

The Gisholt Machine Co., Madison, Wis., have sent us a copy of their new catalogue K3 describing the "Gisholt Universal Tool Grinder." The catalogue contains a matter of 32 pages and is gotten up in an attractive style. The opening pages deal with the advantages to be gained by using this machine. Following are three or four pages devoted to tool grinding by the "Gisholt" method including a number of settings for grinding the different cutters, illustrated. Pages 16 and 18 deal respectively with grinding inserted tool, post tools and the correct forging of tools. Pages 20 and 21 give the principal dimensions and weights and also a list of parts, illustrated, of the tool grinder. Pages 22 to 26 inclusive contain a general description of the machine together with cross sections and a floor plan. The succeeding pages deal briefly with turret lathes and boring mills, and conclude with a map showing the location of Madison accompanied by an invitation to visit that city. The illustrations are exceptionally good and include views of tool rooms, two grinding charts, a sample of tools ground on this grinder, in addition to those already referred to.

Book Reviews

Submarines, Torpedoes, and Mines, by W. E. Dommett, 106 pages 7¼ inches, 21 illustrations and 16 full size plates. Published by Whittaker & Co., London, and New York, price 25c net. This is the second impression of an exceedingly interesting little volume, especially so at the present time when the work of submarines is so much before the public. The author states that in the preparation of this book, the endeavor has been to present the subject in such a manner that it shall be understood by, and together with the plates, be of interest to the general reader, and at the same time contain sufficient technical matter to be of value to the reader having some technical knowledge. The latter feature, however is limited to some extent by the necessity for secrecy enjoined by the various governments or private yards building submarines. That

the book is up to date is proved by the reference to incidents of the present war; viz., the action at Heligoland Bight and the feat of the B. 11 in penetrating the Dardanelles and torpeding a Turkish warship. The book contains ten chapters with the following headings:—Historical, British naval submarines, submarine tactics, steering and manoeuvring apparatus, propelling plant, armament, navigation fittings, routine on submarines, mines, and lastly auxiliary vessels. It will be noted from the above that submarines and their constructions have been covered quite comprehensively. The plates sixteen in number, are excellent reproductions and show various types of submarine craft, while twenty-one illustrations show the propelling engines and other details. Among the latter is included a folding plate illustrating the interior of a submarine. The chapters on torpedoes and mines are also equally interesting, the illustrations being of considerable help to a clear understanding of the text.

HASTE AND WASTE.

IT is hurry in the morning, hurry at noon-time, and hurry at night. Nervous bodies, wrought up to a certain speed, fret away pleasure and good nature just to keep up the pace. Relaxation becomes almost painful—rest a farce. To be in any measure content one feels it necessary to be rushing along "breakneck." No more is accomplished, homes are not the brighter, children the happier, or lives made more useful by all this rush. Yet we keep it up.

One has only to watch the crowds in the cities going to trains or cars to see the working out of the speed mania. Rights of others are forgotten, personal safety seems naught, just crowd, push and get ahead. Strange to say, however, we do not get ahead as quickly as we would if we were to move in a more leisurely manner.

Haste makes waste, and waste is expensive in the extreme. Some persons are too busy to attend to that which insures themselves good health. They expect to mend a broken auto tire hastily and with no skill.

This is an impossibility, but that is not taken into consideration; and so the haste and waste go on, and every day comparatively young men and women let slip from their hands all that is useful and happy in life. Their grasp has grown weak and nothing can be held longer. All due to the daily rush of eating, of working, of walking—everything done hastily, with only a thought for saving an hour or two. Think it over!—Todge Idea.

WHAT REASON HAVE YOU

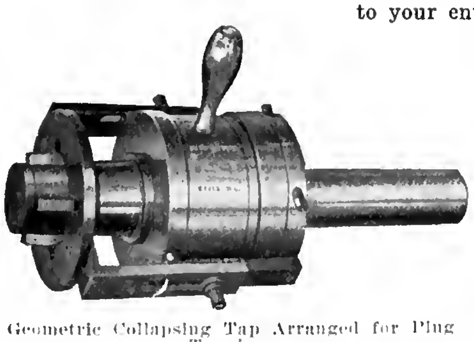
For not using a Geometric Collapsing Tap in tapping out holes above ¾-inch diameter?

Your rate of production would be increased, and your cost of production decreased.

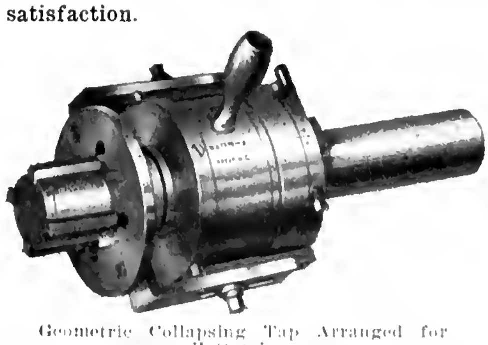
Geometric Collapsing Taps require no backing out over the threads. They are rigid while cutting, but collapse their chasers at the prescribed depth of thread.

It makes no difference what the thread is, a Geometric Collapsing Tap can be furnished that will produce it

to your entire satisfaction.



Geometric Collapsing Tap Arranged for Plug Tapping.



Geometric Collapsing Tap Arranged for Bottoming.

We will fit the tap with whatever size shank your machine requires. Send specifications of your work, and our experts will make a study of it and tell you what we can do for you.

Look over our catalogue. Get in touch with us, at least.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Cobalt, Ont.—The Coniagas Mining Co. will build a new cyanide mill.

Mount Brydges, Ont.—It is probable that an automobile factory will be built here.

Galt, Ont.—The Galt Machine Screw Co. has purchased a site in Jackson Park, and will build a new plant there.

Chatham, N.B.—The Maritime Foundry Co.'s new shell plant is under construction. The building is 100 x 40 feet.

Walkerville, Ont. — The Dominion Stamping Co. will make an extension to their plant.

Goderich, Ont.—The Doty Engine Co. have received an order for 4.5 high explosive shells.

Berlin, Ont.—The Central Heating Co. have ordered two 300 h.p. boilers from the Babcock & Wilcox Co.

Winnipeg, Man.—The city is contemplating making an extension to the power plant at the municipal hospital.

Brampton, Ont.—A company has been formed to make shells here. A factory building on Nelson Street will be utilized.

Renfrew, Ont.—It is reported that M. J. O'Brien is interested in a proposition to establish a factory here for making shells.

Montreal, Que.—The Canada National Gas Co. are calling tenders for the laying of a pipe line from the wells at St. Barnaby to the city of Montreal, a distance of 40 miles. The cost is estimated at about $200,000.

Electrical

Peterborough, Ont.—It is stated that the Hydro-Electric Commission will take over the Healey Falls dam, the property of the Seymour Power Co.

Palmerston, Ont.—The obtaining bylaw for Ontario hydro-electric power was voted on here on Aug. 4, and carried almost unanimously. The projected line starts near Mitchell and supplies Milverton, Listowel, Palmerston, Harriston and Clifford. Milverton, Harriston and Palmerston have decided handsomely in its favor, and the other towns will likely do the same. Hydro is expected to be installed in December.

CANADIAN GOVERNMENT PURCHASING COMMISSION.

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George Gault, Winnipeg; Henry Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

General Industrial

Kerrobert, Sask.—The Federal Elevator Co. will build an elevator here. The contract has been let.

Montreal, Que. — The Consolidated Rubber Co. will make an extension to their factory on Notre Dame street.

London, Ont.—Beatty Bros., Ltd., will make an addition to their factory on York street at a cost of $3,000.

Port Arthur, Ont.—The Barnett & McQueen Co., contractors, have commenced work on the new National elevator.

Vancouver, B.C.—The W. H. Malkin Co., wholesale grocers of this city, are having plans prepared for the installation of up-to-date machinery for the manufacturing of their food products.

Victoria, B.C.—The Imperial Oil Co. bought five lots at Esquimalt, and has begun preliminary work for building an oil depot there. Storage facilities are to be erected and a wharf put up. A. M. Abbey represents the Imperial Oil Company.

The Cowan & Britton, Ltd., plant at Gananoque, Ont., manufacturing butts, hinges and other shelf hardware, established 54 years ago by C. E. Britton and the late O. D. Cowan, has been purchased by the Canada Steel Goods Co., Hamilton, Ont.

Winnipeg, Man.—The establishment of big pulp mills and a pickle factory on the line of the Greater Winnipeg Water District railway is proposed by Controller Midwinter. The controller outlined his plan at a meeting of the board held recently.

ALLIES PURCHASING AGENTS.

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:—

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafculloux, Hotel Brevort, New York: Direction de l'Intendance Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Messrs. S. Ruperti and Alexsieff, care Military Attache, Russian Embassy, Washington, D.C.

Municipal

Vernon, B.C.—The city council may install an auxiliary pumping station.

Sherbrooke, Que.—The city council have purchased a site for the new gas plant.

Owen Sound, Ont.—The council are considering the purchase of a motor hose wagon for the fire department.

Lindsay, Ont.—The Horn Bros' industrial by-law has been given the third reading by the council.

Port Rowan, Ont.—The installation of an electric lighting plant is contemplated by the town council.

St. John, N.B.—The city council are in the market for a quantity of cast iron pipe for water main extensions.

Stratford, Ont.—The town council contemplate purchasing about 1,800 feet of 6-in. cast iron pipe.

Athens, Ont.—The town council are considering installing an electric light and power plant.

Beauceville, Que.—The town council will call for tenders shortly on the construction of water-works, drainage and lighting systems. Engineer, F. Mignault, Sherbrooke, Que.

Toronto, Ont.—It is estimated that it will cost between four and five million dollars to rebuild the Morley avenue sewage disposal plant.

Collingwood, Ont.—A by-law will be submitted to the ratepayers to authorize a loan of $20,000 to the Bryan Mfg. Co. to rebuild their factory.

Sherbrooke, Que.—The Gas and Electric Committee have decided to purchase a motor truck from the Andover Motor Vehicle Co. at a cost of $1,860.

Tavistock, Ont.—J. G. Field has accepted an offer from the council of $3,000 for his electric light plant. Hydro power will be installed in the town.

Winnipeg, Man.—The city council contemplate extensions to the gas distribution system. A considerable quantity of cast iron pipe may be required.

Elmira, Ont.—The town council are considering the installation of a sewage system, estimated to cost $25,000. Engineer, H. J. Bowman, Berlin, Ont.

The Pas, Man.—The town council is considering the installation of a waterworks and sewage system, estimated to cost $80,000. H. H. Elliott, clerk.

Dorchester, Ont.—A by-law has been passed granting a franchise to the Southern Ontario Natural Gas Co., and permitting the laying of gas mains in the municipality.

Petrolia, Ont.—The power by-law and the one authorizing the raising of $35,000 for installing a hydro power plant were finally passed by the town council at a meeting held recently.

Chatham, Ont.—The Hydro-electric Commission has submitted a proposal to the city for using hydro power at the civic pumping plant. The scheme includes the purchase of two centrifugal pumps and motors. Total cost is estimated at $3,000.

Brockville, Ont.—The Light and Water Commissioners have instructed that plans and specifications for filtration and intake be sent to the Provincial Board of Health, Toronto. These are the plans made some time ago. It was also authorized that a new set of plans be prepared by G. Bryson, town engineer, and E. J. Philip, manager, covering the whole proposition for intake and filtration. The approval of the department will be sought as to the best method.

Contracts Awarded

Hamilton, Ont.—The Dominion Sheet Metal Co. have awarded the building contracts for their new factory.

Toronto, Ont.—Purdy, Mansell, Ltd., have been awarded a contract by the Board of Control for a steam pump.

A. R. C. Clark & Son, of St. John, N.B., have been awarded the contract for the construction of a sewerage system.

The Jenckes Machine Co., Sherbrooke, Que., will supply and erect a steel water tank for the town of Bedford, Que., at a cost of $4,675.

The Chatham Bridge Co., Chatham, Ont., have been awarded a contract for pumping machinery by the Chatham Township Council.

Brockville, Ont.—The Light and Water Commissioners have passed a resolution accepting the tender of the Donnelly Wrecking Co. for laying the intake under water for $4,973.

Toronto, Ont.—The Toronto Hydro-Electric Commission has awarded a contract for the supply of 1,000 feet of conductor cable at 42 cents a foot to the Eugene Phillips Electric Co. of Montreal.

Tenders

Ottawa, Ont.—The city council will proceed with the installation of an incinerator. Tenders are being received until Aug. 26. F. C. Askwith is city engineer, from whom particulars may be obtained.

Regina, Sask. — Tenders will be received by the City Commissioners up till Monday, September 6th, 1915, for the supply, delivery and erection of a 7,000,000 gallon pumping unit at the city power house. Specifications and other information may be obtained from J. M. MacKay, Superintendent of waterworks, Regina, Sask.

Toronto, Ont.—Tenders, addressed to the secretary-treasurer of the Board of Education, will be received until Tuesday, August 17, 1915, for all trades for enlargement of Eglinton Public School, also heat regulators and sundry trades in other schools. Specifications may be seen and all information obtained at the office of the superintendent of buildings, City Hall, Toronto.

Burlington, Ont.—Tenders will be received by the secretary of the Board of Water Commissioners until Monday, August 23rd, 1915, for the construction of a reinforced concrete gallery and connections thereto. Plan and specification may be seen at the office of the Water Commissioners, Burlington, or at the office of the engineers, Chipman & Power, Mail Building, Toronto.

WINNING THE BUYER'S FAVOR

THE best possible buyer is not made an actual buyer at a single step. It is one thing to win the buyer's favor for an article and another to make adjustments incident to closing the sale. Winning the buyer's favor is the work of trade paper advertising. Under ordinary conditions it should not be expected to do more.

Drumheller, Alta.—Tenders will be received up till Monday, August 16, 1915, for the following contracts: (1) Supply of about one mile of 6-in. and 4-in. steel or cast iron pipe; (2) valves and hydrants; (3) One return tube boiler and stack; (4) One duplex pump; (5) Materials for 30,000-gallon wood tank and housing; (6) All labor and certain materials for laying water mains, sinking an open well, constructing pumping station, and erecting wood tank and housing. Plans and specifications and other information may be obtained at the offices of the John Galt Engineering Co., Ltd., consulting engineers at Winnipeg and Calgary.

Personal

L. S. Hawkins, chief engineer of the Marconi Wireless Co., of Canada, is visiting Port Arthur, Ont.

David A. Thomas, representative of the British Government, and Gen. Mahon, ordnance expert, have been visiting the Maritime Provinces.

Sir Charles Ross, president of the Ross Rifle Co., Quebec, has been given the temporary rank of colonel in the Canadian militia, according to militia orders just issued.

R. O. McCulloch, secretary-treasurer of the Goldie and McCulloch Co., Ltd., Galt, Ont., has been appointed a director of the Union Bank of Canada.

C. H. Webster, formerly secretary of the Calgary Board of Trade, has been appointed secretary of the Western section of the Canadian Manufacturers' Association.

E. W. Knight, until recently with Frankel Bros., Toronto, has opened an office in the Stair Building, Bay street, Toronto, and will carry on a metal business.

Andrew Malcolm, president of the Andrew Malcolm Furniture Co., Kincardine, Ont., died at his home there on Aug. 9. The deceased was born at Killearn, Scotland, 75 years ago, and came to Canada in 1867, settling in Kincardine in 1874.

A. M. Mosley, who for the past few years has been manager of the National Tube Works at Fort William, Ont., has left for Guelph, Ont., where he will assume a similar executive position with the Page-Hersey Co., an affiliated concern.

C. E. Austin, general manager of the Moose Jaw Mills, Ltd., has been appointed general manager of the Dominion Government interior storage elevators between Fort William and Vancouver, with headquarters at Fort William, Ont.

WANTED — EQUIPMENT FOR MACHINE (repair) shop; weight or accuracy not important as price. Give full details. Box 153, Canadian Machinery. (8)

TO THE USER OF WRENCHES

Users of Wrenches, both Pipe and Monkey Wrenches, will find economy in buying the Trimo makes. A new standard of quality has been set by Trimont Mfg. Company, the makers of these improved wrenches.

Be sure to ask for the Trimo Wrenches, both Pipe and Monkey, which are all-steel goods. They are equipped with Nut Guards that prevent the accidental turning of the adjusting nut in close quarters, and with Steel Frames, in the principal sizes that will not break.

These new Trimos are worth more to the user because of these improvements. Ask for the genuine and take no other. Don't let unfair dealers pass out the imitation on you. The name Trimo is on every Trimo tool.

Very truly yours,

TRIMONT MFG. COMPANY,

Roxbury, Mass.

CLEVELAND RIVETING, CHIPPING, CALKING AND BEADING HAMMERS

MOST POWERFUL AND EFFICIENT AIR TOOLS ON THE MARKET

Cleveland Riveters are made in 20 styles and sizes with driving capacities of ¼-in. to 1½-in. rivets in Boilers, Tanks, Stacks, etc.

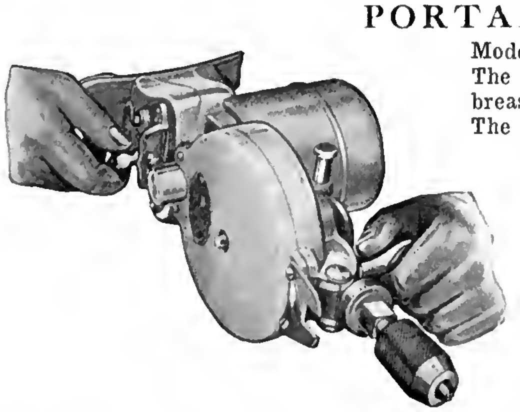
They have an enviable record for durability and economy in service.

CLEVELAND CHIPPING HAMMERS

are made in 20 styles and sizes to suit all classes of work. They are ideal tools for foundries, as they have high speed, no recoil and are practically dust-proof.

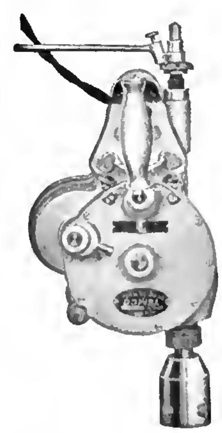
In stock: Riveting and Chipping Hammers, Air Drills, Corner Drills, Sand Rammers, Portable Grinders, Bowes Couplings, Chisels, Rivet Sets, etc.

PORTABLE ELECTRIC DRILLS



Model "B" Drill illustrated, shows compactness of design. The Casing, Switch and Gear Covers are aluminum; the breast plate, motor-head and handle supports are of steel. The machine is light in weight, convenient in shape; has high speed; operates on either A.C. or D.C. currents and runs either forward or reverse as desired. Model "C" has two speeds and in construction is similar to Model B.

Bulletins mailed on request.



Cleveland Pneumatic Tool Co. of Canada, Limited

80 Duchess Street, - Toronto, Ont.

Trade Gossip

Collingwood, Ont.—The Imperial Steel & Wire Co. have closed a large contract for wire and nails.

The Hamilton Bridge Works, Hamilton, Ont., will supply the steel work for the T. Eaton Co. factory.

Ottawa, Ont.—It is reported that the Government contemplate installing shoe machinery in the prison workrooms.

The Goldie & McCulloch Co., of Galt, Ont., have offered a gift of $5,000 to the Canadian Government for war purposes.

The Storey Pump and Equipment Co., New York, have been awarded a contract for pumps by the town of Stratford, Ont.

The International Engineering Works, Toronto, have sold a 12-6-12 in. outside end packed boiler feed pump for the Toronto Island filtration plant.

The Canadian Sarco Engineering Co., Winnipeg, has been awarded a contract by the municipality of Assiniboia, Man., for the supply of 193 Chapman gate valves at $3,500.

St. Andrews, N.B.—The sardine factory at Chamcook, four miles from St. Andrews, has resumed operations after having been closed for the last year. Recently the entire plant and equipment were purchased by the Lane-Libby Fisheries Co., of Boston, Mass.

T. MacAvity & Sons of St. John, N.B., have offered to place at the disposal of the War Office the site and preliminary work on a new plant on Marsh road, on which $10,000 has already been expended. D. A. Thomas, to whom the offer was made, has the matter under consideration.

Orillia, Ont.—The Orillia smelter has begun the treatment of molybdenum. This rare metal is used for hardening steel in connection with the manufacture of guns and other armament. The ore, which is a substitute for nickel, is found in Renfrew County, but it has not been treated in Canada previously.

The Toronto Hydro-Electric Commission has decided that $1,300,000 would have to be provided to carry on necessary extensions and liquidate some of the accounts owing the city. It was pointed out that money would be required to place the Interurban system, recently taken over, in a satisfactory condition.

Canadian Car & Foundry Contract.—The New York Journal of Commerce reports that the Canadian Car & Foundry Co., which early this year received a contract, valued at $83,000,000 from the Russian Government calling for a large

As additional machine tools are installed, new power transmission machinery looms up as important.

The AMERICAN PULLEY COMPANY maintains a constant stock of steel-split pulleys—50,000 of them—for immediate shipment. Sizes from 3" to 72".

These pulleys are 20-year-old successes, and over 2¼ million have been marketed.

Drop us a line to-day for a rapid-fire execution of your wants.

quantity of shrapnel and high explosive shells, has had the original order raised to the sum of $154,000,000.

C.P.R. Taking Over Allan Line.—The C.P.R. Company is taking over the Allan Line steamship business, beginning October 1, this year, a new corporation having been organized in Montreal for this purpose under the name of the Canadian Pacific Steamships, Limited. George M. Bosworth, vice-president of the C.P.R. Company, is the president of the newly-formed Canadian Pacific Steamships, Limited, and H. Maitland Kersey is to be the managing director, with his office in London, England. The new company is to take over all the ocean steamships now operated by the C.P.R. Company and the Allan Line, and the head office will be in Montreal. Messrs. G. M. Bosworth, I. G. Ogden, E. W. Beatty, K.C., vice-president of the C.P.R. Company, and F. E. Meredith, K.C., were the directors in attendance at the organization meeting.

Book Reviews

"The Coking of Coal at Low Temperatures, with Special Reference to the Properties and Composition of the Products," by S. W. Parr and H. L. Olin, has been issued as Bulletin No. 79 of the Engineering Experiment Station of the University of Illinois. This report covers a series of studies made in continuation of the work on the coking of coal at low temperatures, described in Bulletin No. 60. Coke resulting from the low temperature process contains from 18 to 22 per cent. of volatile matter but retains none of the tar forming constituents. In domestic appliances it kindles readily and burns with a bright, smokeless flame. A suction gas-producer test made with this fuel compared favorably in ease of operation and efficiency with similar tests of anthracite. The tar has a specific gravity of 1.069, contains less than 2 per cent. of free carbon and is rich in low boiling substances, many of which are suitable for use in internal combustion engines. Its adaptability to wood preservation processes is shown by its high content of tar acids, which constitute nearly 30 per cent. of the crude material. The pitch residue amounts to 30 per cent. and is low in precipitated carbon. Naphthalene is absent. Results of these studies show that the coke, tar, and gas have specific properties of especial value, and indicate that the process of coking at low temperatures could be established successfully on a commercial basis. Copies of Bulletin No. 79 may be obtained gratis upon application to C. R. Richards, Acting Director of the Engineering Experiment Station, University of Illinois, Urbana, Ill.

Thread Milling Machines

For High Explosive Shells

Designed for the purpose of milling the thread in the base and nose of high explosive shells.

Shell is placed inside a revolving spindle and is self-centering. A perfect thread is produced in base of shell in approximately 2½ minutes.

Milling Cutter is made from best high-speed steel, by Brown & Sharpe, from special design by Holden-Morgan Co., and is so shaped that it can be sharpened without changing the form. Cutter is designed to mill the top of thread as well as the depth.

Machines are fully equipped for work, including oil pump. Fitted with automatic stop motion, which stops machine when thread is completed. One operator can run several machines. Eliminates all risk of having shells rejected on account of thread being stripped, as is liable to be the case when tapped by the old method.

Write for complete particulars, prices, etc.

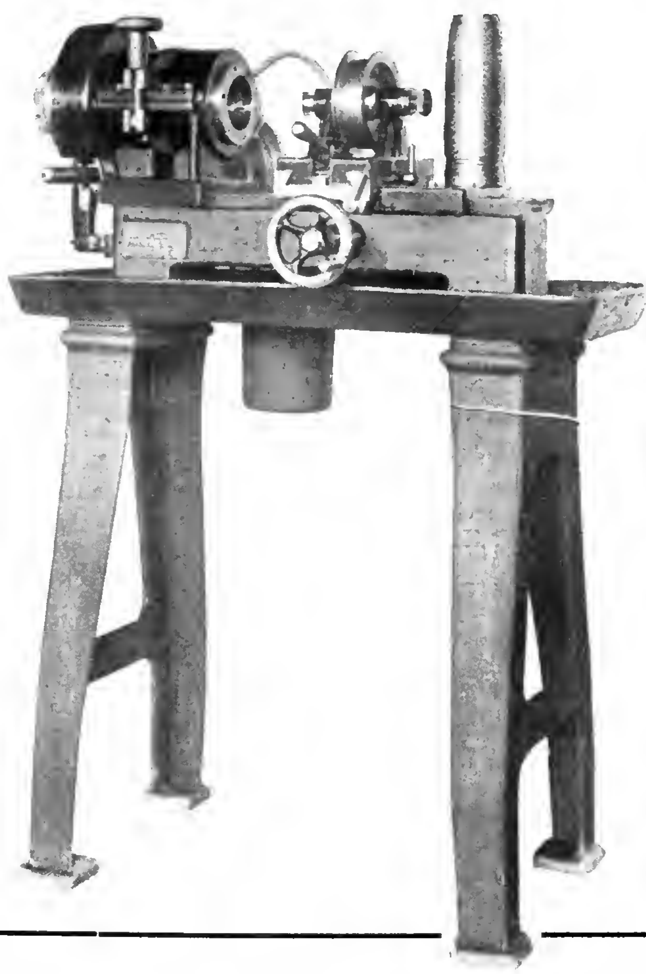
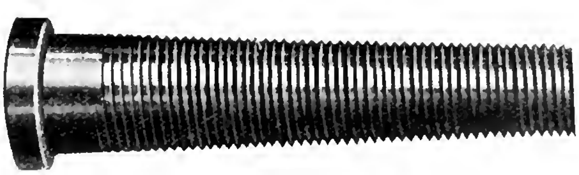
IF IT'S MACHINERY—WRITE "WILLIAMS."



Taper Threading With a Geometric Die Head is a Simple Matter

The chasers follow the taper of the work automatically, and release the work at the end of the cut. Head is withdrawn without touching the finished threads.

Geometric Taper Threading Die Heads are adapted to Screw Machines and Turret Lathes. When not cutting taper threads, the Head can be removed, leaving the machine free for other work.



Made to order, specially suited to requirements of machine and work.

Employed very generally at present on fuse work.

—Consult us about your taper threads—

& Co., of Oshawa. The new building, which will be of fireproof construction, will cost about $30,000 equipped, and work will be commenced at once.

Contracts Awarded

St. John, N.B.—Vroon & Arnold, of this city have been awarded the contract for a quantity of cast iron pipe of various sizes.
tion have awarded a contract to the Dominion Radiation Co., Toronto, for heating and ventilating the new public school. The cost will be $2,527.

Chambly Basin, Que.—The town council have awarded the contract for laying sewer and steel pipe and installing pumps to S. W. Hamilton of Montreal.

Brockville, Ont.—The city council has awarded the contract of $4,600 for the laying of 800 feet of intake pipe to the Donnelly Wrecking Co., Ogdensburg, N.Y.

Montreal, Que.—The Phoenix Bridge and Iron Works, Ltd., have secured the contract for the extension to the Harrison Co. bakery, at Westmount. The new building will be three storeys high, 265 x 140 feet and will cost $200,000.

Collingwood, Ont.—It is announced that the Imperial Steel & Wire Co., will re-open their plant about the end of August. The company has recently booked a large export order for wire and wire nails.

Tenders

St. Hilaire, Que.—The town council are calling tenders for the construction of an electric lighting system.

Ottawa, Ont.—The city council will proceed with the installation of an incinerator. Tenders are being received until Aug. 26. F. C. Askwith is city engineer, from whom particulars may be obtained.

Toronto, Ont.—Tenders will be received by the chairman of the Toronto Electric Commissioners up to Thursday, Aug. 26, for an overhead traveling crane. Specification and form of tender may be obtained from the office of the purchasing agent, 15 Wilton ave., Toronto.

Regina, Sask.—Tenders will be received by the City Commissioners up till Monday, September 6th, 1915, for the supply, delivery and erection of a 7,000,000 gallon pumping unit at the city power house. Specifications and other information may be obtained from J. M. MacKay, Superintendent of waterworks, Regina, Sask.

Burlington, Ont.—Tenders will be received by the secretary of the Board of Water Commissioners until Monday, August 23rd, 1915, for the construction of a reinforced concrete gallery and connections thereto. Plan and specification may be seen at the office of the Water Commissioners, Burlington, or at the office of the engineers, Chipman & Power, Mail Building, Toronto.

Ottawa, Ont.—Tenders will be received until Wednesday, September 1st, 1915, for the manufacture, delivery of, construction and erection complete of sluice pipes, valves, operating machinery and electrical equipment for Swift Rapids Dam, Trent Canal. Plans, specifications and forms of tender can be obtained by application to the chief engineer, Department of Railways and Canals, Ottawa, or to superintending engineer of the Trent Canal, Peterboro, Ont.

Thorold, Ont.—Tenders will be received by the town clerk until Wednesday, August 25th, 1915, for the construction of a system of sanitary sewers in St. Andrews Ward, comprising about 14,225 lineal feet of pipe laying; also for the construction of sewage pumping station. Machinery to be furnished and installed by corporation. Plans and specifications may be seen at the resident engineer's office, Thorold, or at the office of the chief engineers Chipman & Power, Mail Building, Toronto.

Wood-Working

Northland, Ont.—James Bryant's saw mill was destroyed by fire recently.

Kingston, Ont.—S. Anglin & Co. will build a planing mill at a cost of $4,000.

Kingston, Ont.—S. Anglin & Co., are building a planing and sawmill to cost $4,000.

Makamik, Que.—The Makamik Sawmill Co., is building a sawmill to cost $6,000.

Montreal, Que.—The S. & A. Brochin Co., are in the market for woodworking machinery.

Bury, Que.—L. H. Martin's sawmill has been destroyed by fire, with a loss of $8,000, including machinery.

North Bay, Ont.—The Gordon Lumber Co. saw mill has been destroyed by fire. The loss is estimated at $150,000 about half of which is covered by insurance.

Sydenham, Ont.—It is reported that H. M. Woodruff has sold his mill to a Renfrew syndicate, who will convert it into a power plant and also build a sash and door factory.

Milton, N.S.—Fire breaking out in the lumber mill and box factory of the McLeod Pulp Co. destroyed both buildings and a large amount of machinery on July 27. The loss is estimated at something over $10,000 with some insurance.

Personal

Charles F. Gray, of Winnipeg, has been appointed manager of the Watrous Electric Light Co., in succession to W. E. Thorneloe, resigned.

T. A. Kerr, formerly of the Sudbury Construction and Machinery Co., has been appointed general manager of the Nipissing Foundry Co., North Bay, Ont.

Robert Bowie, vice-president of the Canada Foundries & Forgings, Ltd., died at Brockville, Ont., on August 13. The late Mr. Bowie was born in London, England, on March 3, 1840.

H. B. VanEvery, Power Building, Craig st., Montreal, has been appointed Canadian representative of the S. Morgan Smith Co., of York, Pa., manufacturers of hydraulic turbines.

D. A. Thomas, representative in Canada of the Minister of Munitions, has returned to Ottawa from New York, and the Shell Committee and Mr. Thomas' party expect to leave this week to visit shell plants in Ontario and the West.

Louis Charlton Fritch has been appointed general manager of the C. N. R. lines east of Port Arthur, Ont., with headquarters at Toronto. Mr. Fritch, who has been assistant to the president of the railway since March, 1914, was born in 1868 at Springfield, Ill.

George Henderson, son of the late Joseph R. Henderson, succeeds his father as president and general manager of the Brandram-Henderson Company. The new president has been a director for some years, and has had charge of the Maritime end of the business. At the time of his father's death he was preparing to go to the front with the overseas expedition.

New Incorporations

The Sardis Shingle Co., Vancouver, B.C., has been incorporated with a capital stock of $10,000.

a capital stock of $25,000 to manufacture timber, etc.

The Keystone Logging & Mercantile Co., Silverdale, B.C., has been incorporated with a capital stock of $10,000 to manufacture lumber, shingles, etc.

The Burbank Motor Co., Kelowna, B.C., has been incorporated with a capital stock of $15,000 to manufacture automobiles, agricultural implements, etc.

McFee, Henry & McDonald, Ltd., Victoria, B.C., has been incorporated with a capital stock of $50,000 to manufacture drills, drilling machinery and other implements, etc.

The Rosetown Electric Light & Power Co., Rosetown, Sask., has been incorporated with a capital stock of $50,000 to erect plants and generate electricity, light, heat, power, etc.

The R. M. Moore & Co., Vancouver, B.C., has been incorporated with a capital stock of $50,000 by Robert M. Moore and others of Vancouver to manufacture engines, lighting, heating and power machinery, etc.

The Montreal Leather Goods Co. has been incorporated at Ottawa with a capital of $50,000 to make leather goods and machinery at Montreal. Incorporators: A. Papineau Mathieu, Armand Mathieu and Robert T. Mullin, all of Montreal.

C. A. Spencer, Ltd., has been incorporated at Ottawa with a capital of $150,000 to carry on business as contractors at Montreal. Incorporators: A. Huntley Duff, Walter A. Merrill and Phillippe Marchant, all of Montreal.

The Georgian Bay Coal Co., has been incorporated at Ottawa, with a capital of $100,000 to operate and develop mining properties. Head office is at Toronto and the incorporators are Robert Charles Vaughan, Lorne William Mitchell, of Toronto, Ont.

Montreal Motor, Ltd., has been incorporated at Ottawa with a capital of $75,000 to manufacture all kinds of steel goods, projectiles, ammunition and gun carriages, etc., at Montreal. Incorporators: Samuel Bruce Holmes and Edward Charles Baker, all of Montreal.

The George Frid Brick Co. has been incorporated at Toronto with a capital of $40,000 to carry on business as contractors and brick makers at Hamilton, Ont. Incorporators: John Edward Frid, J. A. Forrest and Robert B. Cheyne, all of Hamilton, Ont.

The Canadian Metal Cap and Seal Co. has been incorporated at Ottawa with a capital of $600,000 to manufacture the "Spengler" bottle cap and similar products at Montreal. Incorporators: Leslie H. Boyd, A. R. Johnson and Arthur Ross, all of Montreal.

The Ideal Canning Co. has been incorporated at Ottawa with a capital of $50,000 to carry on a canning business at St. Dorothee, Que. Incorporators: Joseph E. Decelles, Joseph N. Decarie and P. A. Decarie, all of Montreal, Que.

Hubert Villeneuve, Ltd., has been incorporated at Ottawa with a capital of $50,000 to carry on business as contractors, with head office at Montreal. Incorporators: Hubert Villeneuve, J. E. Carpentier and W. J. B. Johnston, all of Montreal. P.Q.

The United Engine & Separator Co., Ltd., has been incorporated at Ottawa to take over the business of the United Engine Co., of Toronto, Ont. The company is capitalized at $50,000 and the incorporators are Robert B. Gardner, Charles E. Lillie and Jeremiah Skelton, all of Toronto.

Trade Gossip

The Nova Scotia Steel & Coal Co. has given four machine guns to the Government for the Canadian expeditionary forces. Officers and clerks of the company at the Sydney mines have promised another.

Ottawa, Ont.—The Ottawa Board of Control at its next meeting will consider the advisability of assisting the Empire in this war by making a grant towards the establishment of a shell factory to sell to the Government at cost, and will later take the matter up with the Shell Committee.

Windsor, Ont.—Secretary Ray, of the Board of Trade, is in receipt of an inquiry from a manufacturing firm in Ohio desirous of establishing a Canadian branch. A building of 5,000 or 10,000 feet of floor space would be suitable, if located on railway switch. The secretary would be glad to hear from anyone who has such a building to offer.

John Bertram & Sons and Pratt & Whitney Co., of Dundas, Ont., and their employees have decided to donate ten machine guns to the Government for the use of Canadian soldiers at the front. A meeting of the employees of both firms was held on Aug. 6 and it was decided that each employee would donate two days' pay and the firms would make up the balance.

St. John, N.B. — New Brunswick Metals, Ltd., a new company, has been organized with an authorized capitalization of $98,000 to operate the antimony

WINNING THE BUYER'S FAVOR

THE best possible buyer is not made an actual buyer at a single step. It is one thing to win the buyer's favor for an article and another to make adjustments incident to closing the sale. Winning the buyer's favor is the work of trade paper advertising. Under ordinary conditions it should not be expected to do more.

For Rapid Production and Accurate Work

USE THE

"BRIGGS"

The Briggs Miller handles work no other machine of its size can touch. It is a manufacturing machine. On account of its rigid construction it will produce accurate work when running at a high rate of speed and feed.

The Base Tank and Large Gear Pump is the latest addition to its many advantages. Tank holds 20 gallons of cutting lubricant.

Pump never requires priming and will deliver ten gallons per minute to the cutters, keeping them cool when run at very high speed.

780

mines at Lake George, 25 miles from Fredericton, J. A. DeCew, chemical engineer of Montreal backed by English capital, is at the head of the enterprise. Arrangements are being made for the operation of the mine on an extensive scale.

St. John, N.B.—The government of New Brunswick, impressed with the necessity of conserving the economic resources of the province, has in view the projection of a scheme of reforestation. As a step in this direction, a classification of the Crown lands has been entered upon. Premier Clarke and Hon. J. D. Landry have been in Quebec lately looking into the plan of reforestation adopted by the government of that province.

Shell Committee Visit Plants.—Members of the Shell Committee and of the party accompanying D. A. Thomas, Lloyd George's agent of munitions in Canada, have returned to Ottawa from their visit to Montreal and the Maritime Provinces, where they inspected factories which are turning out shells. The party will leave in a few days to visit factories in Ontario and the West. They expressed themselves as well satisfied with the manner in which Canadian manufacturers are responding to the call for munitions.

Nickel Output of Canada.—The output of copper-nickel matte in Canada in 1914 was 46,396 gross tons, valued by the producers at the smelter at $7,189,031. It contained 28,895,825 lb. of copper and 45,517,937 lb. of nickel. The ore tonnage smelted was 947,053. The production in 1913 was 47,150 tons of matte containing 25,875,546 lb. of copper and 49,676,772 lb. of nickel. An increase was thus shown in copper content and a decrease in nickel. The world's production of fine nickel in 1913 approximated 34,000 tons, of which the Canadian ore contained 24,838 tons.

Butterfield & Co.—Work has commenced on the new plant of the Butterfield & Co., Rock Island, Que., branch of the Union Twist Drill Co. of Athol, Mass. There will be two buildings, the first 185 feet by 60 feet, three storeys; the second 175 feet by 60 feet, one storey. The new plant will be devoted to the manufacture of the complete line of twist drills and milling cutters which have hitherto not been made in Canada. The present tap and die factory of Butterfield & Co. will be transferred into the new building and the old building probably used for storage and warehouse purposes. The buildings are to be of reinforced concrete construction and it is expected that they will be completed and in operation by December next.

Vancouver, B.C.—As the result of negotiations which have been progressing for the past month with respect to the property and plant of the Ocean Falls, Ltd., the well known pulp and sawmills of this province, a new company has been formed to take over the plant and all the assets of the former company, and to erect a paper mill for the manufacture of that commodity in addition to pulp. The name of the new company is the Pacific Mills, Ltd., in which the Crown-Willamette Paper Co., of Portland and San Francisco are the parties most heavily interested. The new company is capitalized at $9,-500,000. J. H. Lawson, jr., of Vancouver, is to be president of the new concern and W. S. Lane is secretary. The directors are Messrs. N. R. Lang, S. D. Brooks, W. S. Lane, R . R. Parker, and J. H. Lawson, jr., all of Vancouver.

Catalogues

Wood Split Pulleys made by the Oneida Steel Pulley Co., Oneida, N. Y., are described fully in catalogue No. 6. Tables giving prices and shipping weights of the various sizes are included.

Flexible Shafts.—Bulletin No. 54 is devoted to a description of the combinations of "Stow" flexible shaft and electric motor. Particulars are given of the suspended type, of a general utility tool and of a two-spindle drill accompanied by illustrations.

Turbo-Generators.—The many advantages of the turbo-generator in small and moderate sizes are set forth in detail in Bulletin No. 54, just issued by the Kerr Turbine Co., Wellsville, N.Y. Many interesting installations of "Economy" turbo-generators are also described and illustrated. Copies will be mailed upon request.

"Shaw" Compression Couplings are described in a bulletin issued by the Keystone Pulley Co., Oneida, N. Y., who are exclusive agents for this line. The bulletin deals with both the single and double compression flange couplings, and contains tables giving prices and principal dimensions for the various sizes.

Metals.

The feature of the market this week is the continued decline in prices notwithstanding that conditions have changed very little. The inference is that prices are gradually reaching their proper level and that the previous inflated quotations have been due partly to manipulation and also on account of unsettled conditions due to the war. Copper, tin, spelter, and lead are all lower, while antimony, although unchanged is very easy. All solders have declined approximately ½c per pound on account of the weakness in the tin market. The general situation is practically unchanged there being a good demand for metals for munitions.

Tin.—The market is stagnant there being little inquiry for any position with the exception of a few inquiries for early delivery. Tin has declined 1c and is being quoted locally at 39c per pound.

Copper.—The International situation is depressing the market which is dull and weaker. There is very little business moving, both buyers and sellers awaiting political developments. The market has declined 1c locally and Lake copper is now quoted at 19c per pound.

Spelter.—The market is gradually getting into a more normal condition, the recent abnormal prices being the result of speculation. The demand is improving to some extent but the market has declined 4c and quotations are nominal at 16c per pound.

Lead.—The London market is improving slowly but New York is quiet and lower. The "Trust" price is being maintained at $4.50 New York, but sales are being made under that figure. Lead is quoted locally at 6c per pound representing a decline of ½c.

Antimony.—The market is stagnant and an entirely nominal one with a weaker undertone. Quotations are unchanged at 40c. per pound.

Aluminum.—The market is unchanged and quotations entirely nominal at 40c per pound.

CANADA'S DEBT.

THE financial statement of the Dominion to August 1 shows some striking increases in liabilities as compared with the same date last year. In the twelve months there has been an increase in temporary loans of $92,000,000, of $13,000,000 in the net debt, and of $16,000,000 in Dominion notes outstanding. The total gross debt of the Dominion in August 1 was $734,656,544, of which $362,703,312 was payable in London.

Temporary loans included amount to $100,673,684, and Dominion notes outstanding $152,043,872, an increase of $16,111,396 over last year. The total net debt on July 31 was $463,745,092, an increase of $13,457,371 for July.

Customs, excise and post office alike show an increasing revenue for July as compared with July last year. The figures are:

	July, 1914.	July, 1915.
Customs	$6,807,058	$7,240,321
Excise	1,653,050	1,734,477
Post Office	825,000	1,200,000
Public works, including railways	1,678,298	1,152,374
Miscellaneous ..	1,558,215	1,327,917
Total	$12,521,624	$12,655,085

Total revenue for the first four months of the fiscal year was $29,371,327, as against $32,704,870 for the corresponding period last year. July expenditure on capital account (for permanent works) was $3,920,518, of which $3,808,273 was on public works, including railways and canals, and $112,245 for railway subsidies.

The statement does not show war expenditure separately, but the increase in temporary loans is understood to be chiefly accounted for under this head. War expenditure is now averaging approximately $10,000,000 a month.

ALLIES' PURCHASING AGENTS.

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:—

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendance Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Messrs. S. Ruperti and Alexsieff, care Military Attache, Russian Embassy, Washington, D.C.

THE WORLD'S ZINC SUPPLIES.

THE Financial Times of July 26 contains the following notes on zinc, compiled by Rudolf Wolff Kreuger & Co.:—

"We compile statistics every year of the production of virgin and secondary spelters; the last available statistics that we have before us are those for 1913, because, naturally, for 1914, after five months of the great European war, no enemy returns were available. Examining our figures for 1913 we find the total European output was 661,325 tons. Australia gave us 3,666 tons and the United States 508,549 tons. Out of the European total we must now cancel the Belgian, Silesian, Rhenish, Northern French, Austrian and Polish productions; these amount together to 570,152 tons per annum. It, therefore, follows that the onus of supplying the allies with spelter falls upon the United Kingdom, Holland, Spain, Australia and the United States.

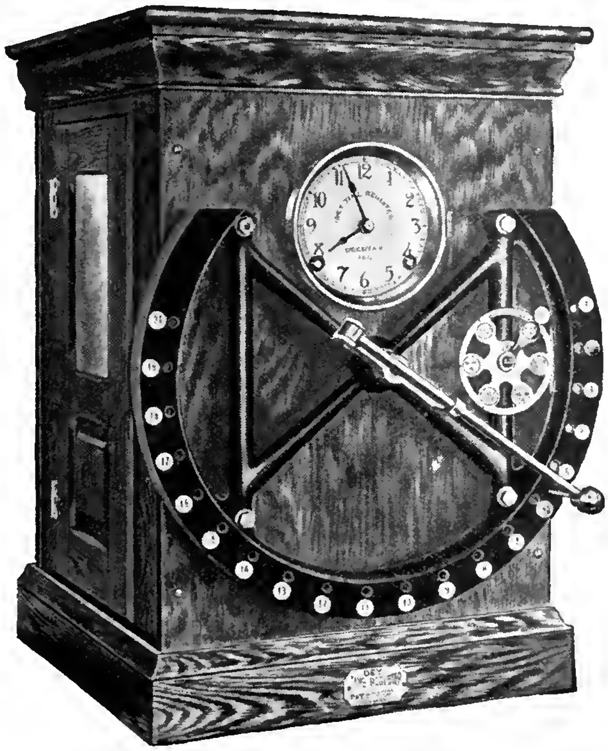
Our own producers have probably slightly increased their output during the present year, but owing to the shortage of labor and the lack of furnace capacity we have not made anything like the advance that we should have done. The Dutch production has certainly fallen off, owing to the extreme difficulty of getting the ores into Holland. (Holland itself produces no zinc ores.) The Spanish production most likely remains unchanged. Australia has undoubtedly developed, and may send us 1,000 to 1,500 tons more this year. To make up for the bulk of the shortage, we have to look to the United States of America. In this respect it is, therefore, interesting to study the figures compiled by the United States Geological Survey. These statistics have already been considered very reliable, and when it is intimated, therefore, that the United States of America during 1915 may be in a position to furnish about 560,000 tons of spelter, this is interesting, as it provides for an increase on their 1913 total of something like 250,000 tons.

War Consumption of Spelter.

"Were the consumption of spelter to take normal course, even this increase on the part of the United States of America would not be sufficient to meet all demands. The price of spelter, however, has risen now to a level, which practically precludes any consumption save that for war purposes. This is a state of affairs which we forecast in many of our previous reports; that it was distasteful to those consumers, who were going to be squeezed out of business, we fully understand, but it was a situation that had to be faced. The requirements of the European war upon spelter are monthly increasing, and it is to be anticipated that consumption for war purposes will grow larger and larger. We think, however, that the smelting capacity among the allies and neutral countries will also increase, and with all normal peace trade suppressed, the equilibrium between supply and demand will be found again.

"Much has also been written about the German control of the vast zinciferous resources of our colonies. Most of the observations made upon this subject we entirely concur with; we have often made allusion to the same thing before, and we think it is pitiable to find a situa-

Here are "3 buys" that run into thousands of dollars



A splendid machine—costs only $85.

Raw Materials
Machinery
Labor

Raw materials are checked, counter-checked and tested. You know what you're getting.

You carefully check the machinery buys—you get guarantees. It would be hard to beat you on these purchases.

Now, the Labor. Ah! the biggest daily buy you make. How do you check IT? Do you get every minute you pay for? Haven't you a right to?

There is just one system that will guarantee this—The International Time Recording Co. Time Clocks and Cost Systems. They play no favorites. They are absolutely automatic, unchangeable—and the employee makes the records himself!

Thousands of firms use the International System. How much did it cost them? That depends on how long they waited before they bought.

There is an International Recorder and System that exactly fits your business, no matter how "different" you think your business is. Ready to save you money. Write us for particulars to-day.

ECONOMIC WATER OIL

SHELL MANUFACTURERS use ECONOMIC WATER OIL for METAL CUTTING of every description; it will not gum nor rust, and it SAVES TIME AND LABOR.

WE CAN SAVE YOU 50% in the **COST** of your **CUTTING MIXTURE** BECAUSE

ONE GALLON of ECONOMIC WATER OIL will mix readily with **30 to 50** gallons of WATER, making a thick, creamy emulsion, and giving you a cutting mixture which will not only be **satisfactory**, but will produce very **ECONOMIC RESULTS.**

One TRIAL ORDER will prove our STATEMENT.

tion created like the present one, owing to the fact that German houses have been always able to contract for our output of colonial concentrates to the detriment of the British buyer.

Present Situation Summary.

"Our summary of the whole position is this: The spelter market may have been, and probably has been to a certain extent, exploited, but the situation at which we have arrived was inevitable, when German houses established the control of the British zinciferous reserves, and made full arrangements for treating the same. We consume alone in the United Kingdom something between 170,000 and 200,000 tons of spelter per annum, and we actually produce about 60,000 tons. At all events, it is satisfactory to know that Lloyd George's recent action has removed any likelihood of a shortage in the large supply needed for munitions."

CANADIAN TRADE SHOWS INCREASE.

THE total Canadian trade for July reached $100,000,000, according to the statement now issued by the Hon. J. D. Reid, Minister of Customs. For the corresponding month of 1914 the total trade amounted to $93,000,000.

The feature of the statement is the large increase in domestic and foreign exports. During the month of July, domestic exports reached $45,600,000 and foreign goods exported from Canada $16,000,000, compared with $41,000,000 domestic and $8,000,000 foreign for the corresponding month of 1914. Eleven million dollars worth of animals and their product was exported during July, being a substantial increase over the corresponding month last year. Manufactured goods also show a good increase, the exports being $12,500,000, against $5,800,000 for July, 1914.

While the exports are soaring, there is a decrease in the merchandise entered for consumption. During July $36,000,000 worth of goods were imported, made up of $20,000,000 dutiable and $15,000,000 free goods. This is a falling off for the corresponding month of 1914, when the imports amounted to $42,000,000, made up of $26,000,000 dutiable and $16,000,000 free goods.

For the four months of the present fiscal year, ending July 31st last, the total Canadian trade was $371,000,000, compared with $306,000,000 for the four months of the corresponding period last year. Last July $13,000,000 worth of corn and bullion was exported.

Truro, N.S—The plant of the Truro Engineering Works has been purchased by the Truro Steel Co.

Stott & Hamilton, of St. Thomas, have been awarded the contract for installing a low pressure steam system for heating the public school at Belmont, Ont.

Shell Tapping

IS THE IDEAL TEST FOR TAPS

They have got to be made right and tempered right to stand up to the job on shell metal.

Butterfield Taps

are just in their element on shell work or any other job where fast cutting on tough materials is required.

They produce more work in a given time and last longer. We know it because we have put them to many working tests against other makes.

Positively Guaranteed.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Toronto, Ont.—The Russell Motor Car Co., have been given an order for shells.

New Glasgow, N.S.—McNeil Brothers, will spend $75,000 on equipment for its plant.

Goderich, Ont.—The Doty Engine Co. are about to purchase machinery for making shells.

Renfrew, Ont.—A building will be erected by Mr. Low, of this town, to be used for the manufacture of shells.

Cowansville, Que.—The Norwood Engineering Co. is erecting a plant for the manufacture of shells and ammunition.

Deseronto, Ont.—It is reported that a syndicate has purchased a site here and propose establishing a plant for making shells.

Toronto, Ont.—The Bawden Machine Co. have obtained a permit for the erection of an addition to their shop, to cost $2,500.

Fort William, Ont.—It is reported that the old Zenith zinc mine at Nipigon Bay will be opened again for active mining operations.

Halifax, N.S.—The Imperial Oil Co. may establish an asphalt and fuel oil refinery here. The company expect to spend $400,000.

St. Catharines, Ont.—The Whitman & Barnes Mfg. Co. will soon begin work on an addition to its plant for the manufacture of tools.

Smith's Falls, Ont.—The Frost & Wood Co. will install $35,000 worth of machinery in its plant for the manufacture of shells, etc.

Bridgeburg, Ont.—It is announced that the King Separator Co., of Buffalo, N.Y., will establish a plant here for assembling parts of their Canadian product.

Kincardine, Ont.—The Hunter Bridge & Boiler Co. expect to commence work on the manufacture of shells for the British Government in the course of a few weeks.

Edmonton, Alta.—G. W. Farrell, of Montreal, is interested in a scheme to develop hydro-electric power at a point on the North Saskatchewan River, near Rocky Rapids, about 60 miles from here.

Hamilton, Ont.—It is reported that the Garland Stove Works have received an order for 500,000 high explosive shells from the French government.

Quebec, Que.—Tenders will be called shortly by the Quebec Streams Commission for the damming of the St. Francis River at a point in the neighborhood of Disraeli, Co. Wolfe, on the Quebec Central Railway. The cost of the work is estimated at $350,000.

Kingston, Ont.—The Canadian Fire Underwriters' Association have recommended that the capacity of the pumping plant be increased, a new boiler purchased for the pumps, and the water main be renewed between the pumping station and standpipe.

New Hamburg, Ont.—On August 20 a fire broke out in the plant of the Electric Meteor and Stamping Metal Co., and the entire building and contents were destroyed. The factory was managed by John Messner and employed about 75 hands. The loss is estimated between $30,000 and $40,000, partly covered by insurance.

Edmonds, B.C.—Plans and specifications have been submitted to the Burnaby Council by the Shell Oil Co., for the building of a plant here. The plans, which entail an expenditure of $110,000, call for the erection of wharfage, crib work, warehouses and several steel tanks having a capacity ranging from 5,000 gallons to 38,000 gallons.

Electrical

Berlin, Ont.—The Light Commission will purchase a number of 25-cycle motors to replace 60-cycle machines.

Listowel, Ont.—Vote is to be taken on August 21st, on a by-law authorizing the installation of a hydro-electric system at a cost of $6,600.

Welland, Ont.—The Hydro-Electric Commission propose to spend $8,000 on a transmission line and transformer at the Weedon Mining Co. plant.

Southampton, Ont.—A by-law providing for the installation of a hydro-electric system at an approximate cost of $13,000 will be submitted shortly.

Lambton, Ont.—Work has been commenced on the erection of a new electric sub-station in Lambton Park by the Toronto Suburban Railway Company.

Thistletown, Ont.—A movement is on foot in the village for the linking up of Thistletown with the hydro-electric system. At present the village is served by a private power concern, which, besides providing some street lights, does a considerable business with the local consumers.

Toronto, Ont.—The Toronto Hydro-Electric Board have applied for the passage of a by-law by the City Council to raise $1,375,000 for new work. The items of the work are given as follows: Sub-feeders and feeders generally, east end station, construction and equipment, additional equipment for direct current supply in downtown district, increased general capacity of station and pole type transformers, additional services and meters, general line extensions, Sterling Road transformer house and equipment, additional requirements for civic car line service, towers to cross new channel for Ashbridge's Bay development and to complete the loop circuit to the Island, and general extensions and improvements as required to meet the general development of the business as required.

Municipal

Victoria, B.C.—The City Council are contemplating the installation of a civic abattoir to cost $20,000.

Liverpool, N.S.—A by-law has been carried to authorize an expenditure of $10,000 on repairs to the electric plant.

Weyburn, Sask.—Work is in progress on the construction of the $15,000 sewage disposal plant here. Engineer, George Reed.

Meaford, Ont.—The ratepayers on August 15 turned down the by-law to sanction improvements to the waterworks system.

Berlin, Ont.—An extension to the sewage disposal plant is under consideration. Chipman & Power, of Toronto, are the engineers.

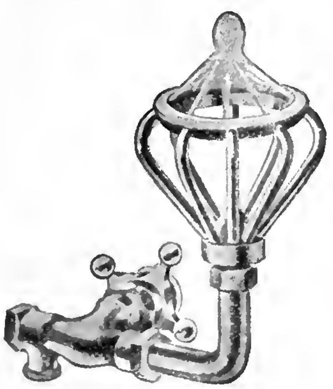
Welland, Ont.—A by-law will be prepared and placed before the Town Council to fix an assessment of $5,000 for the Weedon Mining Co., who propose establishing a zinc smelter here.

JOHNS-MANVILLE SERVICE
COVERS THE CONTINENT

JOHNS-MANVILLE SERVICE TO THE MANUFACTURER

J-M Products are not only the result of experience and expert workmanship on materials of the highest grade, but have behind them the backing of J-M Service and Responsibility. They *must* give absolute satisfaction in service.

J-M Sanitor Drinking Fountain eliminates the contaminations of Bubble Jet as well as those of Public Cup.



The J-M Sanitor Drinking Fountain Head forms a jet of water with eight small streams opposed annularly. All waste water falls within the ring, and does not come in contact with the supply orifice. Contamination is impossible and sterility is assured.

The fountain head itself may be attached to any standard fixture now in place. We supply Drinking Fountains in all styles equipped with the J-M Sanitor Bubbler and fittings to meet any requirement. Ask our nearest branch to show you this head and demonstrate it or send you explanatory literature.

There's a difference between covering steam pipes with "pipe covering" and insulating a steam line with the proper materials.

The business of Johns-Manville Heat Insulation Service is to recommend, sell and install a specific insulation for a specific requirement.

Steam insulation is a study in heat economy and not the dispensing of so many feet of pipe covering so many inches thick.

The purpose of J-M Heat Insulation Service is to furnish efficient insulation on your job so that when the work is done the system is as efficient thermally as it is possible to make it.

Every variety and combination of insulations are manufactured by the Johns-Manville Co. and Johns-Manville specialists are ready to recommend the proper insulation for your work. Why not let them confer with you?

One style of J-M Heat Insulation for pipes over 4½" diameter.

The Canadian H. W. Johns-Manville Co., Ltd.

Manufacturers of Asbestos Roofings; Pipe Coverings; Packings; Mastic Flooring; Conduit; Stack Lining; Fireproof Paint; Fire Extinguishers; Fuses; etc.

TORONTO MONTREAL WINNIPEG VANCOUVER

3132 D, 3100 B

Galt, Ont.—In the smallest vote polled in recent years, a by-law to raise $40,000 for the Waterworks Commission was recently carried by a majority of 169.

Sarnia, Ont.—The City Council is about to take steps to get water from the new waterworks at the lake shore. A scheme has been planned for improving the infiltration basins.

Listowel, Ont.—The hydro by-law authorizing the expenditure of $12,000 on a distribution plant was carried on Aug. 21. Of the above amount, $6,600 will be required in connection with the waterworks system.

Calgary, Alta.—The power and development committee of the City Council held a meeting recently, at which the proposed contract between the city and the Alberta-Electric Co. was endorsed and recommended to the City Council.

Chatham, Ont.—The City Council are considering the purchase of new pumps for the waterworks plant with a capacity of 2,000,000 and 3,000,000 gallons each. One of these pumps is to be a turbine, changeable from electricity to steam. William Gordon and Stewart Lamont are water commissioners.

Windsor, Ont.—Ratepayers voted on two money by-laws on August 18, and, despite very light attendance at the polls, both carried easily. The Devilbiss Atomizer Co. has been granted a fixed assessment of $10,000 on its new factory, and the issuance of $30,000 worth of debentures to cover the cost of local improvement work, completed last year, has been authorized.

General Industrial

Collingwood, Ont.—The Tobey Tannery Co., will make an extension to their plant.

Calgary, Alta.—The Western Canada Flour Mills Co. will build ten new elevators in this district.

Esquimalt, B.C.—The Imperial Oil Co. will commence shortly the erection of an oil refinery, to cost $175,000.

Kamloops, B.C.—H. Nixon is the president of a company who are developing a fruit canning industry in this district.

Milton, Ont.—The Milton Mfg. Co. are installing machinery in their new mill for making textile fabrics, such as plushes and velvets, etc.

Hamilton, Ont.—A by-law has been passed by the council granting permission for a factory to be built by an American firm, who propose locating here.

Three Rivers, Que.—It is rumored that another big pulp and paper mill is to be established in this city and the building of the plant will probably be commenced this fall.

Foremost, Alta.—The Ellison Milling Co. of Lethbridge, have commenced the erection of their new elevator at this point, which will be the third in Foremost. It is understood that the Lake of the Woods Milling Co. will also erect an elevator here, which will make the fourth.

Tenders

Toronto, Ont.—Tenders will be received up to Tuesday, August 31st, 1915, for the supply and erection of screens for windows and doors at the main sewage disposal works. Specifications and forms of tender may be obtained at the Works Department, City Hall.

Ottawa, Ont.—Tenders will be received until Tuesday, August 31st, 1915, for dredging required at mouth of Kaministiquia River, Fort William, Ont. Combined specification and form of tender can be obtained on application to the Secretary, Department of Public Works,, Ottawa.

Toronto, Ont.—Tenders will be received by the Board of Education until Friday, August 27, for all trades for new building, Dovercourt school grounds, Bartlett Ave. Specifications may be seen and all information obtained at the office of the Superintendent of Buildings, City Hall, Toronto.

Toronto, Ont.—Tenders will be received up to Tuesday, August 31st, 1915, for the supply and erection of an electric crane, hoist and single line clam shell bucket at the main sewage disposal works, Toronto. Specifications and forms of tender may be obtained at the Works Department, City Hall.

Regina, Sask.—Tenders will be received by the City Commissioners up till Monday, September 6th, 1915, for the supply, delivery and erection of a 7,000,000 gallon pumping unit at the city power house. Specifications and other information may be obtained from **J. M. MacKay**, Superintendent of Waterworks, Regina, Sask.

Ottawa, Ont.—Tenders will be received until Wednesday, September 1st, 1915, for the manufacture, delivery of, construction and erection complete of sluice pipes, valves, operating machinery and electrical equipment for Swift Rapids Dam, Trent Canal. Plans, specifications and forms of tender can be obtained by application to the chief en-

gineer, Department of Railways and Canals, Ottawa, or to superintending engineer of the Trent Canal, Peterboro, Ont.

Ottawa, Ont.—Tenders will be received at this office until Wednesday, September 8, 1915, for the construction of station, water tank, engine-house, transfer platform, standpipe pit, ash pit and turntable foundations for the Carleton Point Car Ferry Terminal, Prince Edward Island. Plans, specifications and form of tender may be obtained from the chief engineer, Department of Railways, and Canals, Ottawa; the chief engineer, Canadian Government Railways, Moncton, N.B.; and the engineer in charge, Car Ferry Terminals, Carleton Point, P.E.I.

New Incorporations

The Beaver Knitting Mills, Ltd., has been incorporated at Ottawa, with a capital stock of $75,000, to manufacture wearing apparel, in the village of Alton, Ont. Incorporators—Phebe Algie, Janet Dorrington, of Alton, Ont.

The J. R. Eaton & Sons, Ltd., has been incorporated at Ottawa, with a capital of $200,000, to take over the business of the J. R. Eaton & Sons, Ltd., of Orillia, Ont. Incorporators—James Russell Eaton, Edwin Russell Eaton, of Orillia, Ont.

La Compagnie d'Appareils Automatiques, Ltee, has been incorporated at Ottawa, with a capital of $200,000, to build and operate automatic distributors and automatic machines of all kinds at Montreal. Incorporators—Victor Lemay and Pierre Christie, of Montreal.

The Auto Products Co. has been incorporated at Ottawa, with a capital of $250,000, to manufacture automobiles, aeroplanes, auto cars and motor vehicles of all kinds, at Ottawa. Incorporators—Reynolds Delmeige Bray and William Joseph Halpin, of Ottawa.

McVitie & Price, of Canada, Ltd., has been incorporated at Ottawa, with a capital stock of $10,000, to carry on in Canada and elsewhere the business of biscuit manufacturers in all its branches at Montreal. Incorporators—Alexandre Chase Casgrain and Errol Malcolm McDougall, of Montreal.

Ideal Incinerator and Contracting Co. has been incorporated at Ottawa, with a capital stock of $250,000, to take over as a going concern the business carried on by the Ideal Incinerator and Contracting Co., Ltd., at Toronto. Incorporators—George Edward Farley and Allen Earle McFaul, of Toronto.

Advertising

"Advertising is the education of the public as to who you are, where you are, and what you have to offer in the way of skill, talent or commodity. The only man who should not advertise is the man who has nothing to offer the world in the way of commodity or service."—*Elbert Hubbard.*

Canada Cheese Box Co. has been incorporated at Ottawa, with a capital stock of $90,000, to manufacture cheese boxes, barrels ,etc., at Ottawa, Ont. Incorporators—Byron Moses and Robert Kenneth Milks, of Ottawa.

The T. & K. Industries, Ltd., has been incorporated at Ottawa, with a capital stock of $50,000, to carry on the business of mechanical and electrical engineers, tool makers, machinists, founders, metal workers, etc., at Montreal, Que. Incorporators — Henry Judah Trihey and Peter Bercovitch, of Montreal.

The Ottawa Valley Radial Co. has been incorporated at Ottawa, with a capital of $50,000, to manufacture all kinds of explosives, explosive apparatus, explosive by-products ,engine and other fuels, at Ottawa. Incorporators—O. Benjamin Villeneuve, Allan Joseph Fraser and W. J. McCarthy, all of Ottawa.

The Quebec Munitions Co. has been incorporated at Ottawa, with a capital of $50,000, to manufacture all kinds of war munitions, including high explosives and shrapnel shells, fuses, bullets, cartridges, grenades, small arms amunition of all sorts and descriptions at Montreal. Incorporators—Howard Murray, Charles Nicholas Monsarrat and Valentine Irving Smart, all of Montreal, Que.

Trade Gossip

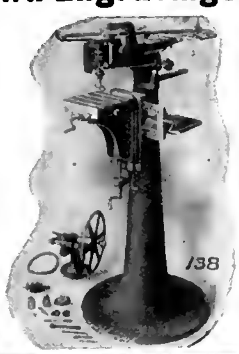
Lucknow, Ont.—The Lucknow Table Co. last week shipped 15,000 feet of lumber for export, to be used in making axles for gun carriages, soup kitchens, etc.

Regina, Sask.—Contract for 500 tons of reinforcing bars for the Robert Simpson Co. new warehouse, has been awarded to Burlington Steel Co., Limited, Hamilton, Ont.

Hamilton, Ont.—It is understood that the National Steel Car Co. has received an order from the Edmonton, Dunvegan and British Columbia Railway for ten stock cars. The value of the consignment was placed at $125,000.

American Foundrymen's Association.—The headquarters of the American Foundrymen's Association during Convention Week in Atlantic City will be the Hotel Traymore, instead of the Marlborough - Blenheim, as first announced.

The Chapman Double Ball Bearing Co., Toronto, are arranging an attractive display for the Canadian National Exhibition at Toronto, commencing Aug. 28th. Visitors will be able to see shells in pro-



cess of manufacture, including copper bands being pressed on. The "Chapman" elevating transfer truck and "Chapman" ball bearings will complete a most interesting exhibit.

Winnipeg, Man.—At a meeting of the Manitoba branch of the Canadian Manufacturers' Association held on Aug. 19, a war purchasing committee was appointed whose duties will be to put forth the claims of Winnipeg when war orders are being distributed, and will strive to influence the powers that be to make the purchases in the West on a larger scale than has been the case in the past. M. F. Christie is chairman of the committee.

Montreal, Que.—W. W. Butler, vice-president of the Canadian Car & Foundry Co., announced last Monday that an order for one hundred box cars, valued at $100,000, had been received from the Alberta Great Waterways Co., and the Edmonton, Dunvegan & British Columbia Railway. The company also secured an order from the same source for $10,000 worth of switch and frog materials, which will be manufactured by their subsidiary, The Canadian Steel Foundries.

Canada Asked to Tender.—The growing importance of Canada in the eyes of the other great portions of the Empire is indicated in the fact that Canadian manufacturers are being invited to tender for large supplies of materials required for the equipment of the North-western Railway of India. Copies of the forms of tender, etc., have been received by the Government at Ottawa. Thousands of brass and steel boiler tubes are called for.

National Steel Car Prospers.—The National Steel Car Co. is making a remarkable showing in point of earnings, which are now running in excess of $100,000 monthly. It is understood that the directors are considering putting the preferred stock on a regular dividend basis of 7 per cent. per annum shortly, and clearing up the back dividends, which will amount to $21 a share at the end of the current quarter. The matter of making up the arrears may, however, go over until the end of the year.

Ottawa, Ont.—It is announced that the new Government grain elevator, under construction at Calgary, will be completed and ready for use by the 1st of September. This completes the chain of internal terminal elevators built by the Government between the Great Lakes and the Mountains, those at Moose Jaw and Saskatoon being already in operation. All these elevators, including, of course, the big elevator at

the head of the lakes, will thus be available for the handling of this year's crop, of which, it is estimated, there will be 175,000,000 bushels for export. The Calgary elevator will have a capacity of two and a half million bushels.

Pembroke, Ont.—A fire recently recently destroyed the plant of the Hardware Specialty Co., the loss being estimated at nearly $15,000 all covered by insurance. The company will rebuild.

Personal

Hon. J. D. Hazen, Minister of Marine and Fisheries, has gone on a tour of inspection down the St. Lawrence. He will inspect the lifeboat and naval stations.

J. W. Eber, who resigned from the general managership of the Toronto, Hamilton & Buffalo Railway a few months ago, died in Hamilton, on Aug. 18.

Ernest L. Ganter, of St. John, N.B., has been appointed assistant inspector of gas and electricity, in the gas and electricity inspection district of St. John.

Josie & McLeod, 49 Gertie street, Winnipeg, are receiving prices and catalogues on hot water boilers, black, galvanized and cast iron pipes; hydraulic pumps, cast and galvanized iron fittings, etc.

Thos. Voyce, of Stratford, Ont., has been given a lieutenant's commission in the 33rd Overseas Battalion. Lieut. Voyce is the 160th employee of the Grand Trunk shops to leave on active service.

David A. Thomas, representative of the British war office on munitions in Canada, is visiting a number of plants in Hamilton, Ont., this week. He is accompanied by Generals Bertram and Mahon and two members of his staff.

R. O. Wynne-Roberts has opened an office at 310 Temple Building, Bay street, Toronto, where he will practice as a consulting engineer. Mr. Wynne-Roberts was at one time consulting engineer to the Saskatchewan Provincial Government investigating lignite deposits and later acted in a similar capacity for the city of Regina reporting on the water supply.

H. P. Meldrum, who for the last two years has been the assistant general secretary of the Canadian Manufacturers' Association in charge of the Eastern Division, has sailed for London, where he will join that part of the staff of the C. P. R. engaged in the purchase of equipment for the Imperial Government. Mr. Meldrum was at one time secretary of the Montreal Branch of the Association.

Contracts Awarded

Hanover, Ont.—The Spiesz Furniture Co., here have received an order for 10,000 shell boxes.

Charlottetown, P.E.I.—A. E. Ponsford, has been awarded the contract for constructing a reservoir at $1,932. and a fuel building at $887.

Toronto, Ont.—The Sheppard & Abbott Co., have been awarded a contract for heating and ventilating the Eglinton public school at $3,415.

Guelph, Ont.—A contract for laying about 4,900 feet of cast iron pipe has been awarded to Brennan & Hollingsworth of Hamilton, at $3,794.

Toronto, Ont.—The Johnson Temperature Regulating Co. will install their appliances in the Eglinton public school. The contract amounted to $747.

Brantford, Ont.—The Brandon Shoe Co. has received an order from the Canadian Government for 8,000 pairs of Canadian army shoes and 15,000 canvas rest shoes for wounded soldiers in hospitals.

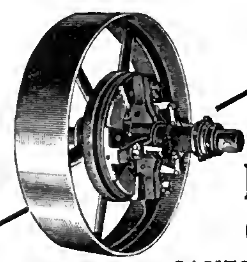
Catalogues

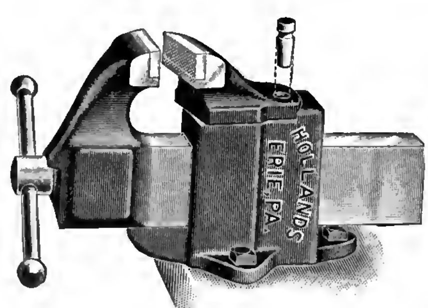
The Mott Sand Blast Mfg. Co., New York, N.Y., have had prepared for distribution four write-ups of different sand blast machines which they manufacture. Copies may be obtained upon application to the company.

Portable Tools, made by the Stow Mfg. Co., Binghampton, N.Y, are dealt with in bulletin No. 400. A complete line of belt and electrically-driven tools is described, which serves to show the different classes of work they are capable of doing. The bulletin is fully illustrated, and is being mailed to the trade.

Burning Crude Oil is the title of a bulletin dealing with one of the principal features of the De la Vergne oil engine, viz., the spray valve and vaporizer. A cross section through the cylinder head shows the construction of the apparatus. Copies of the bulletin may be obtained from the De la Vergne Machine Co., New York, N.Y.

Exhausters.—The Oneida Steel Pulley Co., Chicago, Ill., have issued a bulletin describing steel plate exhausters and cast iron blowers. The bulletin contains a speed, horse-power and pressure table, and also a price list for the exhausters. Another useful table gives the velocity and volume, etc., at given pressures. Among the illustrations are in-





cluded an efficiency curve and diagrams with dimensions for the various sizes.

Crude Oil Engines. — "Munktell" crude oil engines are described in a comprehensive manner in special catalogue No. 5. The method of operation is described at length, each part of the engine being taken in detail. Tables of prices and dimensions are included for each type, accompanied by illustrrations and diagrams. Copies of the catalogue may be obtained from the Canadian representatives, Hyde & Sons, Ltd., Montreal, Que.

Steam Trap Catechism is the title of a new booklet which has just been issued by the American Steam Gauge & Valve Mfg. Co., Boston, Mass. The booklet contains considerable information of interest to users of steam traps, and includes descriptions of various types. Other matter covers the operation of steam traps, water-hammer, and wire-drawing in steam traps, ratings, selection of suitable sizes and limits on buying steam traps, etc. An illustration is shown of the "American" Ideal" trap, accompanied by a diagram and table of dimensions. This booklet may be obtained from the head office of the company, or at any of the branches.

Shop Furnaces is the title of a bulletin recently issued by the American Shop Equipment Co., Chicago, Ill. The bulletin contains particulars covering a line of rivet forges, welding and forge furnaces, hardening and tempering furnaces, etc. The principal features of each type are described, while tables give the principal dimensions and shipping weights of each size. The bulletin has been gotten up particularly with a view to furnishing information for exporters, as the weights are given in both pounds and kilogrammes, and the shipping measurements in both cubic feet and meters. The bulletin is fully illustrated.

Pumps.—Rumsey & Co., Seneca Falls, N.Y., have issued their 1915 catalogue. This is the 56th edition of this publication. It describes an extensive line of hand, force, triplex and centrifugal pumps for all purposes such as domestic, farm, industrial and power plant installations. The catalogue contains a comprehensive description of each type of pump, together with tables giving the principal dimensions, weights, code word and price for each size. The concluding pages contain some useful information and tables for pump calculations, list of repair parts for "Rumsey" pumps with prices, telegraph code, alphabetical index and index to figures in addition to the general index. The catalogue contains 201 pages and is fully illustrated.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Embro, Ont.—H. McDonald will establish a general blacksmith shop here.

Brampton, Ont.—The Pease Foundry has received an additional order for shells.

Ridgeville, Ont.—The Chippewa Gas Co. propose to lay gas mains from Cayuga to St. Catharines.

Ottawa, Ont.—The Russell Natural Gas & Oil Co. is in the market for drilling equipment and pumps.

Calgary, Alta.—The Canadian Western Foundry & Supply Co., with plants in Alberta cities, have received a large order for shells.

Brantford, Ont.—A building permit has been issued to the Brantford Emery Wheel Co. for a $1,500 brick addition to their factory here.

Wingham, Ont.—Owing to increased business, the Western Foundry Co. expects to recommence operations in the new portion of their plant.

London, Ont.—The Wortman & Ward Co. will build an addition to its factory to cost $20,000. The company manufactures iron force and lift pumps, etc.

Welland, Ont.—It is reported that the Electric Steel & Metals, Ltd., are considering building an extension to their plant and installing another furnace.

St. Mary's, Ont.—Additions will be made to the plant of the Thames Quarry Co. A new crusher building, 30 x 60 ft., will be built and new machinery installed.

Lake Megantic, Que.—P. H. Renaud is preparing plans for the erection of a pulp mill. New machinery, including "Baker" cut-off saws, a 70-h.p. engine, etc., will be required.

Nelson, B.C.—The Ivanhoe concentrator at Sandon, B.C., was totally destroyed by fire on Aug. 30. The plant, valued at about $50,000, was treating ore from the Lucky Jim and Surprise mines.

Municipal

Brandon, Man.—The City Council has authorized the extension of the street lighting system.

Beeton, Ont.—The town council contemplate the purchase of boiler and power house equipment.

Guelph, Ont.—The city council will take immediate steps to secure a pulmotor, which will be placed at the firehall.

Oshawa, Ont.—The town council have passed the first reading of a by-law dealing with the steel plant which it is proposed to establish here.

Petrolea, Ont.—The town council has ordered the Hydro-Electric Power Commission to proceed with the construction of an entirely new outfit for the distribution of the hydro light and power.

Sudbury, Ont.—The town council have given permission for the Sudbury and Copper Cliff Suburban Electric Railway Co. to install an electric generating unit in the civic waterworks pumping station.

New Toronto, Ont.—The town will extend its intake 350 feet farther out in the lake, where the water is 25 feet deep. Upon the recommendation of Engineer E. A. James, a tender to do the work for $5,000 was accepted.

Brockville, Ont.—Work is progressing favorably on the preliminary operations necessary for laying the new intake pipe for the Waterworks Department. The Donnelly Wrecking Co., of Kingston, Ont., are the contractors.

Prince George, B.C.—The ratepayers of this city passed four money by-laws as follows:—$80,000 on waterworks; $45,000 on electric light and power system; $15,000 on street improvements, and $10,000 on a city hall.

St. Catharines, Ont.—The ratepayers of St. Catharines will on September 21 vote upon a by-law to grant a franchise to the Relief Natural Gas Co., composed of local capitalists, for the supply of gas to the civic gas plant system.

Moose Jaw, Sask.—The council has decided to purchase from the Turbine Equipment Co., of Toronto, a new electrically-driven pump. The pump is to have a capacity of 700 Imperial gallons per minute, and is for use in pumping crude sewage at the disposal plant.

Markham, Ont.—The village council has decided to install new water mains in the village, also a new tank and collecting basin. The tank is to be 150 feet high and the capacity will be 60,000 Imperial gallons. This new scheme, it is estimated, will cost slightly under $15,000.

Berlin, Ont.—Plans for extension of Berlin's sewage disposal plant have been approved by the Provincial Board of Health. They were prepared by Engineer W. Chapman, of Toronto, and it is expected that when the work is completed the city sewage disposal problem will be solved for some years to come. The cost of the extension will be about $75,000.

Markham, Ont.—At a special meeting of the village council held on Aug. 27, it was decided to submit a by-law to the ratepayers, authorizing the raising of $20,000 for the construction and installation of a modern waterworks system, for both domestic and fire protection purposes. The measure will be given its first reading on Wednesday next, and the vote will be held on October 2nd.

Petrolea, Ont.—The town council on Aug. 23 ordered the Hydro Commission to proceed with the construction of an entirely new outfit for the distribution of the incoming hydro light and power. This action followed the expiry of the time set in which the Petrolea Co. had the option of selling to the town its plant for $15,000. The council turned down the proposed compromise of $16,200 offered by the company.

Weston, Ont.—Providing the Etobicoke Township Council will guarantee sufficient private contracts to secure the Weston Water, Power and Light Commission financially, the latter are quite willing to proceed with the proposed Hydro extension to Thistletown according to their decision at a special meeting held on Aug. 24. The linking up of Thistletown with the local system will involve an expenditure of about $3,200.

Electrical

Granton, Ont.—The vote on the hydro by-law will be taken on September 28, and there seems no doubt that it will pass by a large majority.

St. Thomas, Ont.—The local Hydro-Electric Commission has purchased the property at the corner of Gas and St. Catharine streets for $3,000, and will erect a modern power-house and transmission station. Plans and specifications for this structure are now being prepared by the Provincial Commission.

Trade Gossip

Hespeler, Ont.—The employees of A. B. Jardine & Co. have contributed over $100 towards the purchase of a machine gun.

The Canada Forge Co. and Canadian Billings & Spencer Co. employees and officials have raised $1,000 for a machine gun.

Owen Sound, Ont.—The Northern Bolt & Screw Co. have taken over the Dominion Bolt Co. of West Toronto and will remove the machinery here.

The Cleveland-Sarnia Sawmills have now in their booms in Sarnia Bay, Ont., about 12,000,000 board feet of logs, which are to be sawn up this fall and winter.

The Canadian Fairbanks-Morse Co., Montreal, have been awarded the contract for the conveying machinery for the addition to the No. 1 elevator for the Montreal Harbor Commission.

Windsor, Ont.—The Windsor Industrial Bureau was organized on Aug. 19 in the Board of Trade rooms. Ald. Winter was chosen chairman and T. C. Ray will be the secretary-treasurer. The Board of Trade has raised $960 in subscriptions so far.

The Boving Hydraulic and Engineering Co., Ltd., has been reorganized with the following directorate:—President, Major R. W. Leonard; vice-president, Wm. Flavelle; secretary-treas., T. H. Stinson; directors, Alex. Longwell, Sydney B. Kendall, W. K. George, Jens Orton, Boving, London, England.

Montreal, Que.—Bondholders of the Canadian Cereal and Milling Co. met here on Aug. 26 and decided upon definite plans of reorganization. It was decided to apply to Ottawa for incorporation papers and to organize a new company, which will start with a bond issue of $300,000 and a common stock issue of about $500,000.

The Canadian Locomotive Co., Kingston, Ont., are working on orders for thirty large locomotives for the Russian Government. Russia is thoroughly re-organizing its railway system, which will involve a standardizing of roads, and this will facilitate the filling of later orders by Canadian concerns. The Canadian Locomotive is also filling orders for the Federal Government.

Hamilton, Ont.—In addition to the 400-foot extension to the plant of the Steel Company of Canada, in which have been installed a number of presses for making shells, the company is at work now on a new open hearth furnace for the purpose of supplying raw material for shell making. This new departure will enable the company to secure a primary profit in addition to that of mere assembling of shells.

The Canada Steamship Lines have about twenty per cent. of their vessels serving on the ocean traffic at the present time. While the passenger business of the company, taken altogether, has not been quite up to normal this season, revenue from ocean freight traffic has been substantial. Lake freight rates are high this season, and traffic from the west will be a paying proposition. It is stated that after the interlake season closes a considerable proportion more of the freighter fleet will be transferred to the ocean trade, and in this way a revenue will be maintained during some four months that is usually a blank on the company's books.

General Industrial

London, Ont.—Beatty Bros. will build an addition to their factory to cost $3,000.

Ridgetown, Ont.—D. P. McNorgan of London, Ont., contemplates erecting a flour and grist mill here.

St. Marys, Ont.—William Weir has bought the old Brown Milling Co. property and will convert it into a knitting mill.

Hamilton, Ont. — The Frost Wire Fence Co. will build an addition to their factory. G. E. Mills is the general contractor.

East Toronto, Ont.—One thousand dollars damage was done by a fire which broke out in the drying plant of the Chapman Brock Co., Dawes Road, on August 30.

Vancouver, B.C.—The W. H. Malkin Co. will build a factory. Machinery for the manufacture of food products, etc., will be required.

Parry Sound, Ont.—A fire caused by lightning destroyed two drying houses at the Canadian Explosive Co. plant here on Aug. 24.

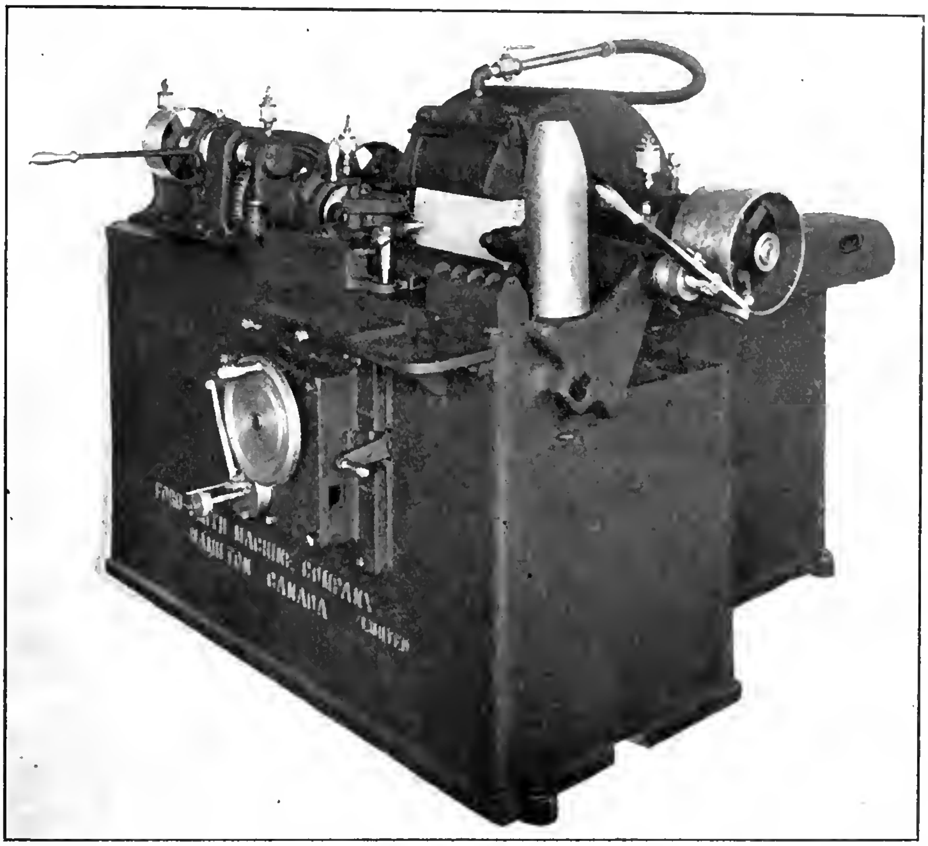
Montreal, Que.—C .H. Johnson & Sons, Ltd., will build an addition to its factory to cost $3,000. The company manufactures wire guards for machinery and other wire goods.

Railways-Bridges

Hamilton, Ont.—A hydro-radial line to St. Catharines and intermediate points is projected.

Three Rivers, Que.—Operations have commenced on the construction of a

The Ford-Smith Shell Grinder



Cut shows trueing device in position on machine arranged for finishing 4.5 shells in one operation.

Unskilled help only required to finish your shells accurately on this Grinder. Does the work of three to five lathes.

Operated entirely from one position; right in front of machine. Nothing to get out of order, and with Belt Power and rigidity to spare.

Our latest model, shown above, is the heaviest and most powerful Grinder on the market for finishing Shrapnel and High Explosive Shells.

Fifty-three of these Grinders are in operation in Canada, United States, and Great Britain, at least one-third of these being repeat orders.

We have evolved a very simple, efficient and inexpensive method of trueing the wheel, using the diamond device only occasionally, and eliminating a big source of expense over earlier practice.

Shells ground in one operation on this machine are true and concentric from base to nose, and the finish is perfect.

We also arrange the machine to grind either body or nose separately for customers whose sequence of operations falls short in this respect.

This machine will solve your lathe question on the finishing operation, and release lathes more suited to roughing and other operations.

The machine is sold complete, ready to run on your particular shells, and our expert's service included. This is not a superficial showing off of the machine, but includes the instruction of your own operators to produce the output.

Get the price and further particulars to-day. Deliveries from stock or within one week.

List of users on application.

The Ford-Smith Machine Company, Limited

HAMILTON, CANADA

If what you want is not advertised in this issue consult the Buyers' Directory at the back.

street railway. The Three Rivers Traction Co. are the owners.

Guelph, Ont.—The Toronto Suburban Railway have almost completed the new electric railway from Toronto to Guelph. Some overhead construction has still to be finished at this end.

Trenton, Ont.—The council will probably submit a by-law shortly for the purpose of authorizing an issue of debentures for $40,000 to cover the town's share of a new bridge. The total cost is estimated at $127,183, the Government paying the balance.

Windsor, Ont.—Plans for a $45,000 bridge on Wyandotte Street, across the M. C. R. tracks, have been approved of by the city council, and the city solicitor has been instructed to make application to the Dominion Railway Board for an order directing the work to be done.

Winnipeg, Man.—The laying of steel on the twenty-five miles of grade east of Foremost, Alta., on what will ultimately be known as the Lethbridge-Weyburn branch of the Canadian Pacific Railway will be started immediately, it has been announced. It is the intention of the company to rush the work to completion as fast as possible.

Refrigeration

Amherstburg, Ont.—The Falls Barron Co. will build a cold storage plant to cost $10,000.

Victoria, B.C.—The establishment of a public abattoir is being considered by the city council. Estimated cost of plant is $20,000.

Amherstburg, Ont.—The erection of a cold storage plant, at an estimated cost of $10,000, is contemplated by the Falls Barron Co. of this town.

St. Thomas, Ont.—The St. Thomas Packing Co., Ltd., may rebuild a portion of their plant, which was recently destroyed by fire. General Manager, J. Moody.

Tenders

Tavistock, Ont.—Tenders will be called at once for the erection of a distribution station in Tavistock for hydro-electric power.

Winnipeg, Man.—Tenders are now being called for the construction of a bridge at Headingly, to be built by the municipality of Assiniboia, with assistance under the Good Roads Act.

Toronto, Ont.—Tenders will be received up to Tuesday, September 7th, 1915, for constructing radial brick chimney for incinerating plant on Don Roadway. Specifications and form of tender may be obtained at Street Commissioner's Office.

Regina, Sask.—Tenders will be received by the City Commissioners up till Monday, September 6, 1915, for the supply, delivery and erection of a 7,000,000-gallon pumping unit at the city power house. Specifications and other information may be obtained from J. M. MacKay, superintendent of waterworks, Regina, Sask.

Quebec, Que.—Tenders for storage dam at the outlet of Lake St. Francis will be received at the office of the Quebec Streams Commission, Room 264, Parliament Buildings, Quebec, until Tuesday, September 7, 1915. Plans and specifications can be seen at the above office or at the Quebec Streams Commission's office, Room 803, McGill Building, Montreal.

Berlin, Ont.—Tenders will be received by the City Clerk until Tuesday, September 7th, 1915, for the construction of sewage disposal works, comprising tanks, filters, sludge beds and pumping station. Plans and specifications may be seen at the office of the Consulting Engineers, Chipman & Power, 204 Mail Building, Toronto, also at the City Engineer's Office, Berlin.

Toronto, Ont.—Tenders for underground work, addressed to the Chairman of Toronto Electrical Commissioners, will be received until Tuesday, Sept. 7. Details of work to be performed consisting of laying cable ducts, building manholes and transformer vaults. Plans specifications and form of tender may be obtained at the Purchasing and Engineering Dept., 15 Wilton avenue.

Ottawa, Ont.—Tenders will be received at this office until Wednesday, September 8, 1915, for the construction of station, water tank, engine-house, transfer platform, standpipe pit, ash pit and turntable foundations for the Carleton Point Car Ferry Terminal, Prince Edward Island. Plans, specifications, and form of tender may be obtained from the chief engineer, Department of Railways and Canals, Ottawa; the chief engineer, Canadian Government Railways, Moncton, N.B.; and the engineer in charge, Car Ferry Terminals, Carleton Point, P.E.I.

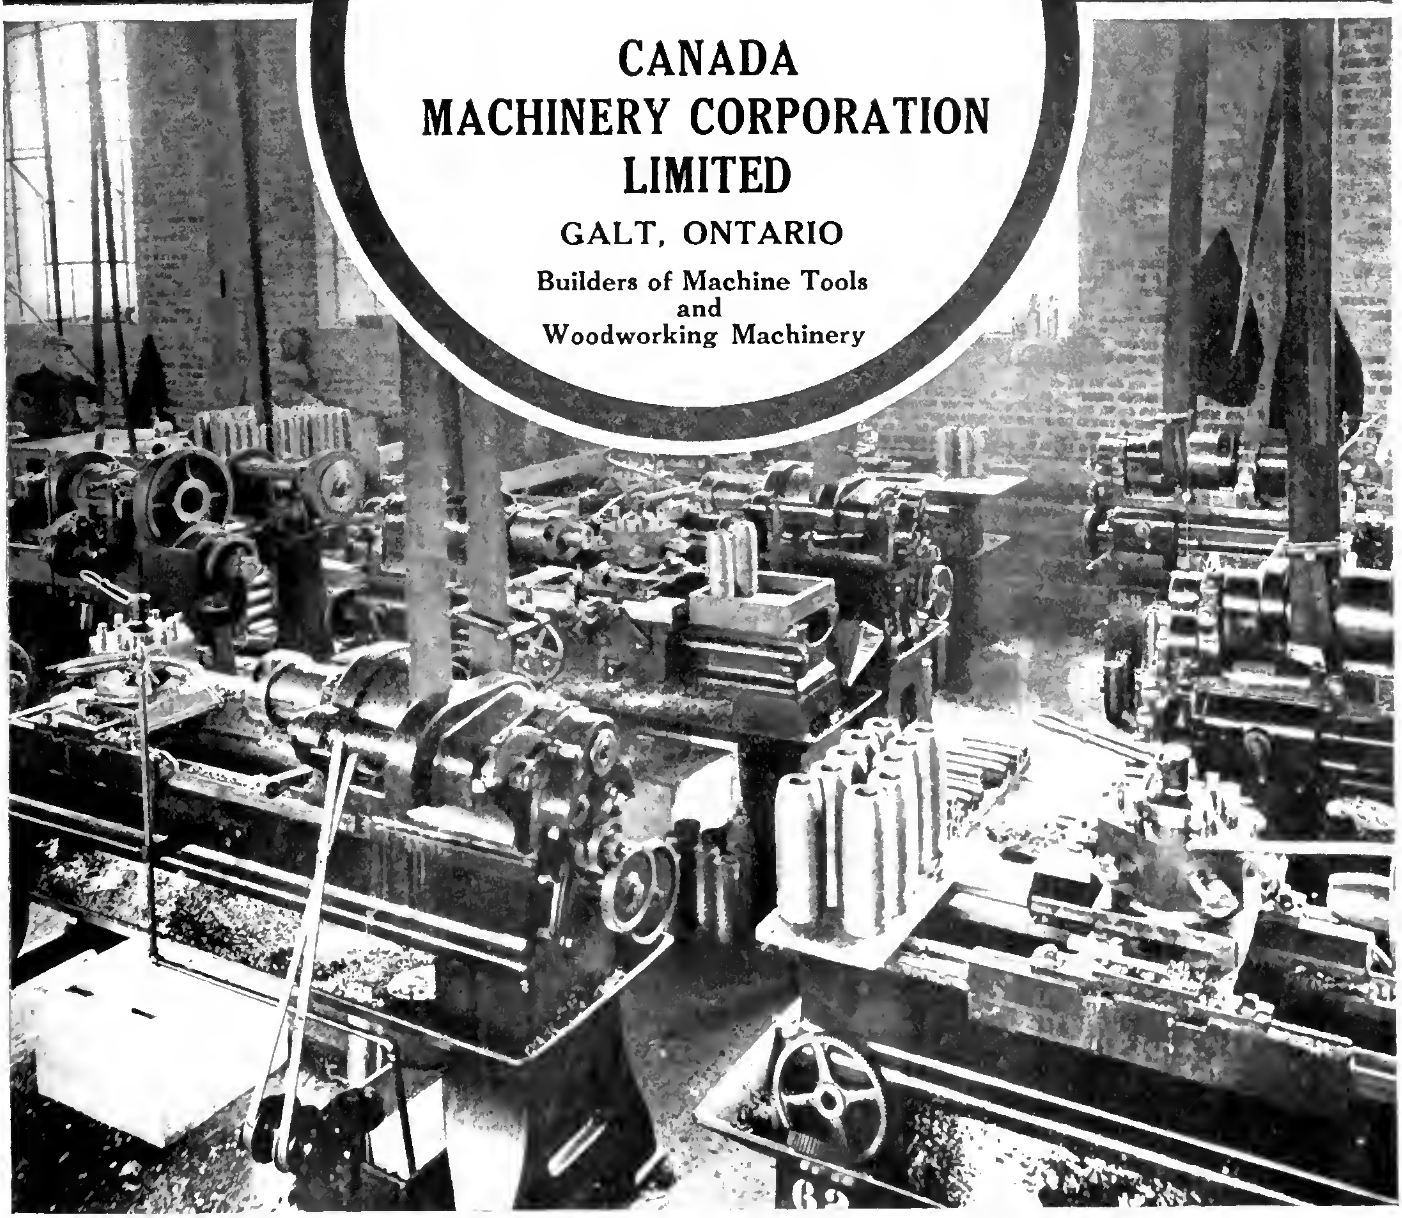
CANADA MACHINERY CORPORATION LIMITED

GALT, ONTARIO

Builders of Machine Tools and Woodworking Machinery



R. W. ASHCROFT HONORED

A NUMBER of American manufacturers, such as the Winchester Repeating Arms Co., the Yale & Towne Mfg. Co., Berry Brothers, Ltd., L. S. Starrett & Co., and thirty-six others, who are members of an organization known as the Rice Leaders of the World Association, have conferred a high honor on one of Montreal's business men.

Somewhat over a year ago, they offered nearly $3,500 cash prizes for ideas and suggestions. This was open to anybody, and the ideas and suggestions could relate to production, sales, advertising or anything else.

The object of the offer was to develop suggestions that would tend to improve the methods or products of these American manufacturers.

But one idea could be submitted to each manufacturer, no two ideas could be alike, and each idea had to be compressed into fifty words.

R. W. ASHCROFT.
Manager of publicity for the Canadian Consolidated Rubber Co., Limited.

Thousands of Americans entered the contest, together with a few Canadians, Britishers and others, and the Second Prize of $500 cash has been won by a Canadian, R. W. Ashcroft, of Montreal, who is manager of publicity for the Canadian Consolidated Rubber Co., Limited, and Associated Companies.

In presenting the prize, Elwood E. Rice, president of the association, wrote Mr. Ashcroft as follows:

"To have earned this second prize in this international competition where people in all walks of life from all parts of the world entered, is cer-

"Hercules" Twist Drills

FOR HIGH EXPLOSIVE SHELLS

PROOF OF THE BACKBONE OF A DRILL IS IN DRILLING SHELLS.
IF A DRILL HAS ANY WEAKNESS THIS CLASS OF WORK WILL QUICKLY BRING IT OUT.
THE "HERCULES" HAS SCORED A WONDERFUL SUCCESS IN MUNITION PLANTS—A FACT THAT STRONGLY RECOMMENDS IT FOR ANY DRILLING JOB IN THE PLANT.
The "Hercules" superiority is due to the use of High Percentage Vanadium High-Speed Steel and the only "**Twisted-While-Hot-Process**" that retains all the strength of the steel in the finished drill. The backbone is all there because the grain of the steel is undisturbed, insuring longer edge-holding and greater resistance to the strains of drilling the toughest of metals.
We also make special Finishing and Roughing REAMERS for shells.

The Whitman & Barnes Mfg. Co.
Established 1854

Ontario

tainly a great evidence of your unusual ability, and in which you are indeed justified in taking exceptional pride.

"I extend to you my best wishes for the continued success your able efforts so richly deserve."

This is not only a feather in Mr. Ashcroft's cap, but is also a compliment to the business ability of Canadians, particularly in view of the fact that Mr. Ashcroft only heard of the contest a few weeks before it closed last May, and therefore had but very little time in which to compile and submit his ideas.

No special publicity was given to the contest in Canada, so those resident in the United States, who had a whole year in which to evolve ideas, naturally had a better opportunity than Canadians to successfully compete.

Contracts Awarded

Brampton, Ont.—The Copeland-Chatterson Co. have let the contract for an addition to their factory to Hill & McCulloch.

Renfrew, Ont.—The Renfrew Electric Co. recently received a large order from the Northern Electric Co., which hitherto had been buying these particular goods from an American concern.

Montreal, Que.—The contract for the structural steel for the addition to No. 1 elevator for the Harbor Commission has been let to the Dominion Bridge Co., Lachine, Que.

The Canadian Brakeshoe Co., of Sherbrooke, Que., have placed an order for the installation of a Snyder electric furnace for the melting of steel. The steel will be used for the manufacture of 4 in. rounds to be forged into shells for the British Government. The Snyder electric furnace is being installed under guarantee as to operating cost. These furnaces are built by the Snyder Electric Furnace Co., Chicago, Ill.

Wood-Working

Matsqui, B.C.—T. Z. Smith will build a factory for the manufacture of boxes.

Sidney, N.S.—Wrights, Ltd., will build a furniture factory to cost $25,000.

Petrolia, Ont.—R. D. Hall will build a factory for the manufacture of gates and woodenware of all kinds.

Montreal, Que.—H. A. Broehu, 294 St. Catherine street, east, is asking information and prices on wood-working machinery, etc.

Bishops' Falls, Nfld.—The Albert F. Reed Co. plans the erection of a factory for the manufacture of wood pulp, lumber, timber, etc.

Catalogues

Norton Ball Bearing Jack made by A. E. Norton, Ltd., Coaticook, Que. Catalogue No. 28 describes a complete line featuring the various types of ball-bearing jacks. Tables give the principal dimensions, weight and list price of each size, and are accompanied by illustrations of the different types and repair parts. Interested readers may obtain copies by writing the company.

Link-Belt and Sprocket Wheels.—The Link-Belt Co., Philadelphia, Pa., are distributing Section A of general catalogue No. 110, dealing with the original "Ewart" detachable link-belt and sprocket wheels. A large number of full-size cuts are shown of standard and special sizes of "Ewart" link-belts and a number of attachments are also illustrated. The catalogue also contains a brief description and price list of attachments, also price lists of sprocket wheels and "Ewart" detachable link-belts.

Betson's Plastic Fire Brick for one-piece boiler furnace linings is the title of a 20-page booklet being distributed. The Betson Plastic Fire Brick Co. Rome, N.Y., make this material. The booklet tells how to construct a solid gas-tight, one-piece boiler furnace lining throughout from this plastic refractory material without the use of any special tools. It gives directions for the testing of boiler settings for air leaks, and for the immediate repair, without shut-down, of cracks and holes, to preserve the life of ordinary brick linings to the time when they can be replaced. Illustrations and diagrams show the one-piece lining as applied to the several types of boilers in general use. Copies of this book will be sent on request to those concerned with the management of boilers.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Sherbrooke, Que.—The Eustis Mining Co. plant has been destroyed by fire, the loss being estimated at $50,000.

Murray Bay, Que.—The boiler-room and laundry at the Manoir Richelieu have been destroyed by fire, the loss being estimated at $20,000.

Brighton, Ont.—The D. J. Barker Foundry Co. have let the contract for the erection of a foundry to Thomas Garnett & Sons, Port Hope. Estimated cost, $13,000.

Burnaby, B.C.—The Shell Oil Co. will spend $110,000 on improvements and buildings to be constructed at its plant as well as the erection of six tanks with a capacity of from 5,000 to 38,000 gallons each.

Hamilton, Ont.—The Canadian Horse Shoe Co. which was recently incorporated with a capital stock of $300,000, is erecting a plant which will represent an outlay of $150,000. The plant will ultimately require the addition of a rolling mill.

Chatham, Ont.—Representatives of an automobile concern, believed to be located in Brantford, are negotiating with the Canadian Wolverine Mfg. Co. for the purchase of their plant on St. Clair Street, apparently with the object of starting the manufacturing of automobiles here. The Wolverine Co. has decided to discontinue manufacturing certain lines of brass goods, but have not formulated definite plans for the future.

Municipal

Thetford Mines, Que.—A waterworks system will be installed at a cost of $12,000.

New Westminster, B.C.—The City Council are considering laying a 14-in. water main to cost $15,000.

Edmonton, Alta.—A by-law is contemplated to raise $250,000 for the building of a sewage disposal plant.

Guelph, Ont.—The city will spend $24,500 on extensions to be made to the water works plant. F. McArthur is the engineer.

Listowel, Ont.—The by-law providing for the construction of a waterworks system has been carried, and tenders will be called shortly. Approximate cost, $5,400.

Cochrane, Ont.—The Town Council will shortly call for tenders on extensions to the water and sewerage systems.

Welland, Ont.—A by-law will be voted on by the ratepayers on Sept. 20 to fix an assessment of $5,000 for ten years to the Weedon Mining Co., who propose establishing a zinc smelter here.

Youngstown, Alta.—A by-law is contemplated to provide $8,400 for the purchase of fire apparatus, sinking well, building fire hall, and putting in tank and reservoir.

Markham, Ont.—The village council have decided to submit a by-law to the ratepayers on October 2, authorizing the raising of $20,000 for the construction and installation of a modern waterworks system.

St. Hyacinthe, Que.—A by-law will be submitted to the ratepayers on September 16 providing for the construction of gravity filters and the installation of two pumps, motor, boilers, pipe connections, valves, etc., estimated to cost $75,000.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen, constitute the Commission appointed to make all purchases under the Dominion $100,000,000 was appropriation:—George Gault, Winnipeg; Henry Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

Owen Sound, Ont.—At a joint meeting of the Utilities Commission and the Finance and Fire Committees held on September 1, it was decided to recommend to the council the extension of the high pressure waterworks system to the factory district on the west side of the town. It is estimated that the cost of the proposed extensions will be in the neighborhood of $5,000.

Electrical

Dutton, Ont.—Hydro was officially turned on here on August 30 by Sir Adam Beck.

Harriston, Ont.—At a special meeting of the Town Council the hydro-electric by-law, recently approved by the ratepayers, was given its third reading.

Chatham, Ont.—At a meeting held at Kent Centre on August 20 farmers of the district decided to have an engineer prepare estimates of the cost of erecting a hydro distributing line into that part of the county.

General Industrial

Winnipeg, Man.—The Auto Light Gas Mfg. Co. will build a new plant at 462 Lipton street.

Ottawa, Ont.—The Ottawa Sanitary Laundry Co. is building a new laundry at an estimated cost of $40,000. M. M. Pyke is manager.

Winnipeg, Man.—The Concrete Post Co.. which already has factories in Saskatchewan and Ontario, has recently secured quarters for a factory in Winnipeg situated on James street east.

Cochrane, Ont.—The Metagami Pulp & Paper Co. are about to commence operations in connection with the establishment of a pulp and paper mill on the Metagami River, thirty miles west of this place

Building Notes

Montreal, Que.—A permit has been issued to the Ogilvie Flour Mills Co. for alterations to their mill here. The cost is estimated at $3,500.

Port Arthur, Ont.—A permit has been issued to the National Elevator Co. for the erection of an elevator at Third Avenue and King street. Approximate cost, $15,000.

Hamilton, Ont.—The Canadian Cartridge Co. have secured a permit to extend their office building at a cost of $2,000. Christman & Co. have the contract.

Winnipeg, Man.—All the tenders for the new Ford building to be erected at the corner of Portage Avenue and Wall Street are now in, the time limit having expired.

Winnipeg, Man.—Work has started on a contract which the Carter-Halls-Aldinger Co. has obtained for the erection of a big assembling plant for the Ford Company at Portage avenue and

Wall street. The building, which will cost about $200,000, will be of reinforced concrete, with exterior walls of red, pressed brick. It will be 200 feet by 150 feet, and will be four storeys high.

Contracts Awarded

Berlin, Ont.—The Kaufman Rubber Co. has received an order for hip boots from the British Government, valued at $40,000.

James Malcolm, of the Andrew Malcolm Furniture Co., Kincardine, Ont., has secured a contract for the making of shell boxes.

Lachine, Que.—The contract for the construction of an incinerator has been let by the City Council to the Atlas Construction Co., Montreal, at $9,000.

Point Pelee, Ont.—The contract for the erection of a lighthouse tower has been let by the Department of Marine and Fisheries, Ottawa, to Charles Mattaini, Fergus, Ont., at $8,490.

Toronto, Ont.—Contract for supply and installation of 7,000 ft. 13,200 volt, paper-insulated, lead-covered cable has been awarded to Eugene Phillips Electrical Works, Montreal, by the Toronto Hydro-Electrical System.

Maillardville, B.C.—The Widdess, McDonald Co., of Vancouver, have been awarded the contract for supplying the material necessary for the installation of the Maillardville water system at a figure of $3,249.25 by the Coquitlam Council.

Drumheller, Alta.—The following contracts have been awarded in connection with the installation of the waterworks system:—E. R. Leverton, Calgary, construction of system, $5,170; elevated tank and housing, Vancouver Wood Pipe & Tank Co., Vancouver, $1,145; duplex pump, Canadian Western Foundry & Supply Co., Calgary, $410; boiler, etc., E. Leonard & Sons, Ltd., Calgary, $1,127; hydrants, Empire Waterworks Supply Co., Winnipeg, $47.11 each; 6-inch valves, Canadian Western Foundry & Supply Co., $10.77 each; 6-inch steel pipe and specials, General Supplies, Ltd., Calgary, 59c per foot.

New Incorporations

The Patent Grates Co. has been incorporated at Ottawa, with a capital of $50,000, to manufacture patent boiler grates at Sorel, Que. Incorporators—Arthur Langlois, Francis Hurtubise, of Montreal.

The Burnall, Ltd., has been incorporated at Toronto, with a capital of $100,000, to manufacture lighting and heating plants at Toronto. Incorporators—Bessie Cook, William Henry Latimer, of Toronto.

Everyman's Car Co. has been incorporated at Ottawa with a capital of $40,000 to manufacture motor cars, trucks and motor vehicles of all kinds at Ottawa. Incorporators, Arthur Meredith Jacques, Frank H. Jacques, and Charles A. Jacques, all of Montreal.

British-American Chemical Co. has been incorporated at Ottawa with a capital of $50,000 to manufacture chemical for medicinal and industrial purposes at Montreal. Incorporators, Errol Languedoc, Ralph Erskine, Allan and Ernest Copeland, all of Montreal.

The Excel Chemical Co. has been incorporated at Ottawa, with a capital of $1,000,000, to manufacture all kinds of chemicals, explosives and other products of a similar nature at Montreal, Que. Incorporators—Eugene H. Godin and Joseph E. Morier, all of Montreal.

ALLIES' PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:—

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendance Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Messrs. S. Ruperti and Alexsieff, care Military Attache, Russian Embassy, Washington, D.C.

The Flexible Metal Hose Co. has been incorporated at Ottawa, with a capital of $200,000, to take over the business of Charles Forth, manufacturer of flexible metal hose and other products. Incorporators—James B. Watson, Francis E. Higgerty, of Ottawa.

The Zinc Co. has been incorporated at Ottawa, with a capital of $100,000, to operate zinc mines and smelters at Sherbrooke, Que. Incorporators — Leland Drew Adams, Charles Herbert Maxey, of Oaklands, Cal., and John Perley Wells, of Sherbrooke, Que.

The Capital Electric Co. has been incorporated at Ottawa, with a capital of $40,000 to carry on business as iron-founders and machinists at Ottawa, Ont. Incorporators, Robert P. Moodie, Edward Thomas Headley and Bernard Gillies, all of Ottawa.

The Russell Fireproofing Co. has been incorporated at Ottawa with a capital of $250,000 to manufacture fireproofing materials, brick and tile, etc., at Russell, Ont. Incorporators, Andrew Walker, Hiram Kenney and James A. Cochrane, all of Russell, Ont.

Marine

Port Arthur, Ont.—The steamers Turret Cape, Turret Chief and Paliki are to be added to those formerly on the Great Lakes and now doing service on the Atlantic. All were ocean-going vessels before being brought to the lakes.

Steamer Condemned.—The steamer Helen R., plying between North Bay and the French River, has been condemned by Government officers, and is now laid up at the wharf, North Bay. She failed to carry the necessary lifeboats and belts as required by law.

Submarine Destructiveness.—Lloyd's official report for the quarter ended August 12 gives the loss to British shipping by submarines as 77 vessels. At that fearful rate, says the Wall Street Journal, there won't be anything left of the British merchant marine in 200 years.

Montreal, Que.—After spending five weeks in dry dock at St. John's, Newfoundland, the steamer Polan Hall arrived in Montreal on September 2. In a dense fog the vessel ran into a short cliff, about 100 feet high, just north of Cape Race, and pounded on a rocky bottom for an hour before being relieved.

New Brunswick Shipping Situation.—The announcement has been made that the British deck-load law will not come into operation this year until November 15. This will mean that steamships with summer deck-loads will be able to clear from New Brunswick ports up to November 1 at least. This extension will mean a period of greatly increased activity at St. John. So far this year the summer shipping business has been ahead of last year.

Montreal, Que.—The master of the steamer Alexandria, Captain William Bloomfield, was justified in his action in beaching the vessel, in a judgment given on September 3, by Captain L. A. Demers, Dominion Wreck Commissioner. The Alexandria was lost in a hurricane off Scarboro Bluffs, near Toronto, on August 3. The master ran her on the beach and she went to pieces. The commissioner finds no fault with this ac-

tion, and exonerates everybody else in connection with it.

Personal

R. W. Hendry, of Hendry, Ltd., has been appointed managing director of the Halifax and Sheet Harbor Steamship Co., Halifax, N.S.

R. J. Cluff has resigned his position as general manager of Steel & Radiation, Ltd., Toronto, to engage in the manufacture of war munitions.

Geo. L. Williams, of Brampton, Ont., has taken over the management of a shoe factory in Toronto and left for that city last week to assume control.

Charles A. Murton has been appointed sole representative in Hamilton, Ont., of the Ahern Safe Co., Montreal, the well-known makers of fire-proof safes, vault doors, etc.

Hon. Finlay McDiarmid, Minister of Public Works, and Hon. I. B. Lucas, Attorney General for Ontario, who have been touring Western Canada, have returned to Toronto.

John L. Feeney, of Fredericton, N.B., has been appointed by the Provincial Government of New Brunswick to the position of road engineer in charge of all important highway improvements.

John Knox, treasurer of the Dominion Power & Transmission Co., died at his home, 15 Robinson street, Hamilton, Ont., on Aug. 31. The late Mr. Knox was born at Kilwinning, Ayrshire, Scotland, and came to this city 32 years ago.

Giles S. Ransom died at his late residence, 386 Indian Road, Toronto, Ont., on Aug. 31, at the age of 62. The late Mr. Ransom was born in Buffalo, N.Y., in 1853, where he received his education. About 40 years ago he came to Toronto, where he has resided ever since. For the past 27 years he had been president of the Toronto Furnace & Crematory Co.

Trade Gossip

Hespeler, Ont.—The employees of the R. Forbes Co. have raised $750 towards the purchase of a machine gun.

The Dominion Canners, Ltd., whose head office is at Hamilton, Ont., have taken over the British-Canadian Canning Co.

The North Bay Iron Works, of North Bay, Ont., have secured a contract from the Sturgeon Falls Pulp & Paper Co. to supply all castings and machine work for a year. The contract will amount to at least $25,000.

The Northern Canada Power Co. have decided to increase their plant in Porcupine to an extent that will cost them at least one million dollars.

The A. B. Jardine Co., Hespeler, Ont., have sent a cheque for $300 to the local machine gun fund on behalf of the company and employees.

Munitions Manufacture.—It is reported that 10,000 brass cartridge cases for shrapnel shells are being turned out each day in the Montreal district.

Customs Notice. — Steam towing winches are now manufactured in Canada by the Corbet Foundry & Machine Co., of Owen Sound, Ont., and are, therefore, not entitled to entry under tariff item No. 470.

The Process Engineers, Ltd., of Montreal, Que., have leased for three years the antimony mines owned by the Canadian Antimony Co. at Lake George, York County, N.B., about 25 miles from Fredericton, and operations will be commenced immediately.

The Imperial Oil Co., Toronto, announce that married men among the employees of the corporation who have enlisted or may enlist for active service overseas will receive half pay and single men quarter pay until the end of the war. In addition, the company will hold the men's positions open for them on their return.

Montreal, Que.—A comprehensive scheme is on foot to erect a large exhibition building or "Palace of Industry" for the holding of trade exhibitions in the Montreal area, and in particular for a large industrial fair in the spring of 1917, according to a statement by T. C. Kirby, manager of the Montreal Automobile Trade Association, Ltd.

Ontario Nickel Commission. — The chairman of the new Ontario Nickel Commission, George T. Holloway, London, Eng., has arrived in Canada and has already met his colleagues, Prof. Miller, Provincial Geologist; T. W. Gibson, Deputy Minister of Mines, and Macgregor Young, K.C. The first steps of the Commission will be a thorough examination of the Sudbury nickel industry, to be followed by a visit to the big New Jersey refining plants, where most of Ontario's nickel ore is treated. One of the Commission's duties will be to prepare an estimate of the extent of Ontario's nickel ore bodies, which would be necessary as a basis for permanent taxation policy.

Collingwood Shipbuilding Co.—The annual general meeting of the Collingwood Shipbuilding Co. was held on Sept. 1. The usual financial statements and balance sheets were presented and we under-

stand were of a satisfactory character, considering the dull period of the first half of the company's year. The following were elected directors: Thos. Long, Toronto; Capt. Alex. McDougall, Duluth; S. H. Lindsay, Collingwood; P. M. Campbell, Collingwood; H. B. Smith, Owen Sound; S. Dyment, Barrie; M. P. Byrnes, Collingwood; T. P. Long, Collingwood. At a subsequent meeting of the directors, the following officers were elected: President, Thos. Long; Vice-President, Capt. Alex. McDougall; Secretary-Treasurer, S. H. Lindsay.

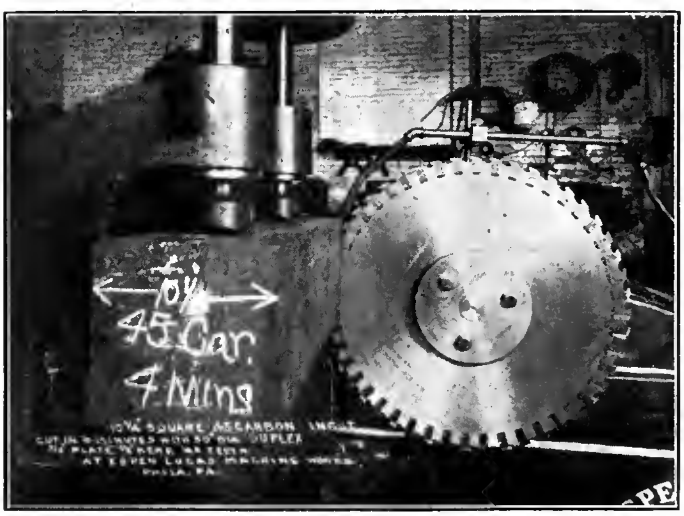
Heavy Exports Anticipated.—Inquiry of shipping companies brings responses to the effect that there is a big demand for grain for all periods from now to the close of navigation, and that this demand extends to all other classes of cargo as well. That is to say, large quantities are demanded of flour, cheese, deals, and provisions, as well as of manufactured articles of every description. One feature in the export trade, which of itself makes this a remarkable year as compared with all past ones in the history of the port of Montreal, is the export of large quantities of steel in billets, tubes, bars and all kinds of shapes. In previous years it has been rather a case of importing such articles than exporting them. Apples will also commence to move freely about the middle of September. With these cargoes in prospect the various steamship lines look for a very heavy export business this fall.

Catalogues

"Burd" Piston Rings.—Bulletin describing the "Burd" high compression rings, made by the Burd High Compression Ring Co., Rockford, Ill. The principal features of this ring are dealt with at length, accompanied by illustrations showing the general construction.

Machinists' Tools.—The National Machinery and Supply Co., Hamilton, Ont., have issued a new catalogue dealing with machinist and woodworker tools, such as vises, planes, handscrews, clamps, etc. The catalogue is fully illustrated and prices are included for each product.

Dixon's Graphite Brushes is the title of a booklet, which explains how the characteristic lubricating qualities of graphite are utilized for reducing commutator troubles to a minimum. The entire booklet is recommended for careful consideration, especially page 3, where the advantages of graphite are clearly set forth. A copy of the booklet may be obtained free upon request from the Joseph Dixon Crucible Co., Jersey City, N.J.



A Chain of Evidence is the title of a publication, No. 13, recently issued by the Morse Chain Co., Ithaca, N.Y., illustrating and describing the "Morse" silent chain and showing a few applications in textile mills. The illustration shows several "Morse" chain drives, each being accompanied by particulars of the drive.

Steel Sheet Piling.—Bulletin No. 108 describes fully arched web, straight web, centre flange protected and plate types of steel sheet piling made by the Lackawanna Steel Co., Lackawanna, N.Y. A number of excellent half-tones show many interesting installations featuring the wide scope of this product. Cross sections are shown of the various types, together with weights and dimensions, while an efficiency table is also included. A brief description accompanies each illustration explaining the principal features of the work shown in the view. The catalogue contains much interesting and useful information on steel piling and its application. The general agents for Canada are the H. A. Drury Co., Ltd., Montreal, Que.

THE A. R. WILLIAMS MACHINERY CO., LTD.

The A. R. WILLIAMS MACHINERY CO., Limited,
Toronto, Winnipeg, St. John, N.B.

Tenders for Scrap.—Sealed tenders for the purchase of a quantity of scrap metal at the Dominion Arsenal, Quebec, will be received up to noon of Thursday, the 23rd day of September, 1915. The quantities are approximately as follows:

	Lbs.
Brass, etc.	16,000
Charger steel	81,120
Steel, tool, lumps	13,950
Steel, mild, lumps	129,232
Turnings	72,074
Cast iron	183,848

The prices should be for delivery, ex stores, Dominion Arsenal, Quebec, material to be removed within 30 days after acceptance of tender. All the scrap is loose, and information required may be obtained from the Superintendent, Dominion Arsenal, Quebec; or Department of Militia and Defence, Ottawa.

Trade Gossip

The Canadian Iron Foundries, Ltd., Montreal, have been awarded a contract for the supply of cast iron pipe to the city of Hull, Que.

St. John's, Nfld.—W. F. Mackay has made application to the City Commissioners for permission to erect a small smelting plant near the west end water front.

The General Supply Co. of Canada, Ottawa, Ont., have opened an office at 408 McGill Building, Montreal, in charge of G. W. Robb. They handle railway supplies, concrete machinery, pumps, etc.

Smith's Falls, Ont.—M. G. Henniger and J. S. Gould, of this town, have purchased an interest in the Rideau Power Co., of Merrickville, Ont. It is understood that the policy under the new arrangement will be to develop power to its fullest extent.

Pit Props to England.—If the war continues Newfoundland expects to ship one million cords of pit props next season for English collieries. During the season just passed, fifty steamers took cargoes running from 5,000 to 20,000 cords each. This was all that was cut last winter.

Canada Iron Corporation—It is announced authoritatively that the affairs of the Canada Iron Corporation, which went into liquidation about two years ago, and the assets of which were taken over by the Canada Iron Foundries, Ltd., will be wound up about the end of the present month.

Steel Billets Higher.—It is reported from Pittsburgh, Pa., that the constantly increasing demand for shrapnel bar is causing the price of steel billets to jump, until a maximum limit has been reached, and buyers in the open market are declaring quotations to be prohibitive.

Nickel Commission at Work.—The Ontario Nickel Commission got down to business on September 10, when it paid a visit to the smelters at Deloro, Ontario. The commission will form its own itinerary, having been given almost carte blanche by the Hon. G. Howard Ferguson, Minister of Lands, Forests, and Mines.

Canadian Gen. Electric Co.—While the ordinary trade of the Canadian General Electric Company has been a little slack during the year so far, war orders have enabled it to maintain its strong financial position and keep up the dividend on the basis that has persisted for some 25 years. The war orders were officially stated recently to be of considerable proportions.

Niagara Falls, Ont.—Engineers of the Ontario Hydro-Electric Commission have just completed a survey for an Ontario Government power-house on the Smeaton farm between Queenstown Heights and Niagara Falls, Ont. It is planned to use the surplus waters of the Welland Canal to develop 300,000 horse-power, carrying the water to the generating station through a canal running from the Chippewa creek.

The Transmission Ball Bearing Co., Buffalo, N.Y., has been incorporated with a capital stock of $100,000 to manufacture ball bearings for factory transmission and for engines, motors and trucks. The directors of the new company (which is the United States branch of the Chapman Double Ball Bearing Company of Toronto) are W. J. Murray and J. P. Beatty, of Toronto, and W. Morse Wilson, of Buffalo. The office of the company is at 1407 West Avenue, Buffalo, N.Y.

U. S. Munitions Export.—American exports of war supplies are increasing enormously now that converted munitions plants are getting into full swing. Figures made public by the Bureau of Foreign and Domestic Commerce show that shipments of horses, mules, automobiles, aeroplanes and explosives, all classed as war supplies, aggregated nearly $50,000,000 in July. The principal increase compared with June exports was in the classification of "all other explosives," including shells and other ammunitions of special manufacture, which jumped from $5,911,929 to $9,329,303. Automobiles, the only item to show a material decrease, dropped from $14,500,000 to $11,000,000.

Steel Co. of Canada.—Figures of earnings of the Steel Co. of Canada, for July, are not yet available, but it is learned that they were well in excess of the June figures, which indicated profits at the annual rate of 21 per cent. on the common stock. In the first half of 1915,

the company did a gross business of about $6,400,000. Its best year's gross was 1912, when orders totalling nearly $16,000,000 were filled. Gross in the second half of 1915 should be at least $10,000,000, which would make the year a record one. Net earnings for 1915 are conservatively estimated at about $3,200,000, this estimate being based on suppositious earnings of $400,000 monthly for the second half.

Canadian Car & Foundry Co.—Advices from New York state that negotiations for the purchase by the Russian Government from the Canadian Car & Foundry Co. of 3,000,000 sharpnel and high explosive shells at a cost of $52,000,000 have been virtually completed. The information was given out at the New York office of the company. Canadian Car & Foundry have already received contracts from the Russian Government valued at nearly $100,000,000. The contract calls for the delivery of the ammunition by April of next year and part of the work will be sublet. Russian funds, it is understood, in Wall Street, have been sent to New York and Canada to cover payment. The contract, it was announced, covers orders for additional shells just as soon as the present ones are turned out.

Personal

Frank Morgan, for 29 years with the Cowan Co., Galt., has been appointed manager of the Dominion Bronze Co., Preston, Ont.

Charles Hothan, of the Brantford Motor Truck Co., has completed a new bayonet and automatic wire entanglement cutter.

E. J. Chamberlain, president of the Grand Trunk Railway, and party of officials, are on their way to Prince Rupert, B.C., on their annual tour of inspection.

Edward Cahill, general manager of the Winnipeg branch of the Gray-Campbell, Ltd., makers of mill equipment and machinery, Chatham, Ont., died suddenly at Hanley, Sask., on September 1. He was 55 years of age.

Hon. T. W. Crothers, Minister of Labor, has left Ottawa on a trip to Western Canada. He will go through to the coast and up as far as Prince Rupert. The Minister of Labor will stop off at all the principal cities and inquire into industrial conditions. At Vancouver he will attend the Dominion Trades and Labor Congress.

The G. H. Tod Co., engineers, late of Manning Chambers, Toronto, have transferred their business to 10-20 Croft Street, city, where a machine shop has been equipped for carrying on a general

engineering business. The company will continue to handle "Bennis" stokers and "Ashworth-Parker" engines, etc., and will in addition be in a position to build machinery and tools for the trade.

D. A. Thomas, the special representative of the British Minister of Munitions, left Ottawa on September 9 for New York. He has completed his work in Canada for the time at least, but will, it is understood, remain in New York. Mr. Thomas' inspection of the munition manufactories in Canada and his conferences with Canadian manufacturers have resulted satisfactorily. He has had several conferences with Sir Robert Borden since the latter's return from England.

Capt. P. M. Campbell, a director of the Collingwood Shipbuilding Co., died at Collingwood, Ont., on September 10, at the age of 69. Capt. Campbell was for many years commodore of the Great Northern Transit Co. fleet, which was later merged into the Northern Navigation Co. He was also one of the founders of the Georgian Bay Navigation Co. Capt. Campbell was one of the original directors of the Collingwood Drydock Co., which ultimately became the Collingwood Shipbuilding Co., of which he was a director up to the time of his death.

D. M. Medcalf, chief inspector of steam boilers for the Province of Ontario, has left for a tour of the Western provinces to confer with the heads of the boiler inspection departments of the Provinces of Manitoba, Saskatchewan, Alberta and British Columbia, with regard to the standardization of rules covering boiler construction and inspection, and to arrange for boilers built under Ontario regulations being accepted by the other provinces. Mr. Medcalf will also visit the Panama-Pacific Exhibition at San Francisco, Cal.

Sir William Cornelius Van Horne, K.C.M.G., at one time president of the C.P.R., died in Montreal on September 11, following a comparatively brief illness. Sir Wm. Van Horne was born at Joliet, Ill., on February 3, 1843, the son of a lawyer. He entered the railway service as a telegraph operator on the Illinois Central Railway in 1857, served in various capacities on the Michigan Central Railway 1858-64, for three years as train despatcher. He was superintendent of telegraphs for a year and divisional superintendent for three years while with the Chicago and Alton Railway, 1864-72; was general superintendent of the St. Louis, Kansas City and Northern Railway, 1872-4; general manager of the Southern Minnesota Railway, 1874-8, and president 1878-9; general manager of the Canadian Pacific

For Rapid Production and Accurate Work

USE THE

"BRIGGS"

The Briggs Miller handles work no other machine of its size can touch. It is a manufacturing machine. On account of its rigid construction it will produce accurate work when running at a high rate of speed and feed.

Fast

The Base Tank and Large Gear Pump is the latest addition to its many advantages. Tank holds 20 gallons of cutting lubricant.

Pump never requires priming and will deliver ten gallons per minute to the cutters, keeping them cool when run at very high speed.

Our booklet describes fully. Drop a card for it.

LYMBURNER LIMITED
5-15 Commissioners St. Montreal, P. Que.

Railway, 1882-4, carrying the road to completion; vice-president 1884-8, president 1888-1899, and chairman of the board of directors 1899-1910, after which he continued on the directorate. In recent years he took a leading part in railway development in Cuba, and he has been interested in many large railway, industrial and financial enterprises.

Catalogues

Forcing Presses.—Catalogue No. 92 deals with the line of hydraulic forcing presses made by the Watson-Stillman Co., New York. A number of presses for various purposes are described and illustrated, making altogether a very complete line. Included is a copper hand-press for shell work.

"**Wrought Iron Railing,** Entrance Gates and Wire Fencing" is the title of a 64-page handsomely illustrated catalogue issued by the J. W. Fiske Iron Works, 78-80 Park Place, New York. This catalogue also includes outside lighting fixtures, mesh wire work for tool and stock room enclosures, and ornamental iron grille work.

Norton Ball Bearing Jack made by A. E. Norton, Ltd., Coaticook, Que. Catalogue No. 28 describes a complete line, featuring the various types of ball-bearing jacks. Tables give the principal dimensions, weight and list price of each size, and are accompanied by illustrations of the different types and repair parts. Interested readers may obtain copies by writing the company.

The Dodge Manufacturing Co., Toronto, have published a report compiled by Professor Price of Toronto University on the properties of wood-split and iron pulleys. The report records a scientific test showing loss from slippage of belts on metal pulleys and the comparative advantages of wood-split pulleys. It also describes the tests in detail and contains a considerable amount of useful information on power transmissions by belts and pulleys. A number of interesting curve and tabulated sheets are included in the report.

Link-Belt and Sprocket Wheels.—The Link-Belt Co., Philadelphia, Pa., are distributing Section A of general catalogue No. 110, dealing with the original "Ewart" detachable link-belt and sprocket wheels. A large number of full-size cuts are shown of standard and special sizes of "Ewart" link-belts and a number of attachments are also illustrated. The catalogue also contains a brief description and price list of attachments, also price lists of sprocket wheels and "Ewart" detachable link-belts.

lower. Antimony has declined 2c and is quoted at 38c per pound.

Aluminum.—There is a considerable increase in the demand for aluminum and the scarcity continues. Quotations have advanced 2c, and are strong at 40c per pound.

INTERNATIONAL NICKEL COMPANY

THE Wall Street Journal says that the International Nickel Co. is receiving and taking care of enormous orders for nickel, its by-products and copper without difficulty.

Nickel is now being used in greater quantities than ever before, due to the abnormal demand for automobiles, manufactured steel products and submarines. The latest use for nickel is in the new electric batteries for submarines, invented by Thomas A. Edison, which will prevent the generation of chlorine gas. In this instance nickel supplants lead.

Another source of increased revenue is the high price of copper. The company's ore recovery is estimated to be about 70 per cent. nickel and 30 per cent. copper. In a year many millions of pounds of copper are produced and sold.

The company owns the most extensive known existing nickel ore deposits. Its patented nickel lands in Ontario, Canada, cover 100,000 acres, and in addition to this the company owns the Town of Copper Cliff, where it has an up-to-date smelting plant. It also owns the shares of the Societe Miniere Caledonienne of New Caledonia, which company owns extensive nickel lands. These lands, it is estimated, will furnish the company with at least 60 years' ore supply.

Earnings during the months of June, July and August, according to well-informed interests, were at the rate of between 25 per cent. and 30 per cent. a year on the common stock. Last year earnings were equal to 13.31 per cent. on the stock.

The company is now paying dividends at the rate of 20 per cent. per annum, having paid 5 per cent. in June and the same tmount in September. This rate will be continued during the remainder of the year, and interests close to the company say it is not unlikely that an extra cash or a stock disbursement will be made this year.

NEW COMMISSION ON PRODUCTION

THE names of the new commission decided upon by the Dominion Government for the purpose of investigating and reporting upon conditions of production, transportation and employment in Canada will be announced shortly. This is the commission of which the late Sir William Van Horne was to have been chairman. His death will necessitate the selection of a new commissioner conversant with transportation and kindred subjects, as the railway facilities of the Dominion provide one of the most important aspects of the problem which is to be solved, particularly the question of a proper system of branch lines to support the great East and West trunk lines already constructed.

The Order-in-Council provides for an investigation of matters relating to scientific production, increased acreage and improved methods, the existing facilities for marketing both at home and abroad, the desirability of providing proper highways and cold storage facilities and the importance of co-operative action by producers. The question of unemployment and immigration, particularly with regard to the expected influx when the war is over, is to be reported upon, and a method devised for so handling this immigration as to promote the cultivation of the great areas of idle land in the Dominion. Questions affecting Canada's position as a borrowing country are also embraced in the Order-in-Council.

Engineering

Tweed, Ont.—Wm. Garrett & Sons foundry and machine shop has been taken over by S. G. Way of Belleville, Ont.

Halifax, N.S.—The Imperial Oil Co., Montreal, is contemplating the erection of an asphalt and fuel oil refinery at Halifax, to cost $400,000.

Toronto, Ont.—W. H. Banfield & Sons have applied for permission to erect an addition to their shell factory on Pape avenue. The addition is estimated to cost about $1,500.

New Westminster, B.C.—The Schaake Co. will install a machine shop at the former Schaake Machine Works. The shops will manufacture machinery for shingle mills, sawmills and canneries, and will also have a capacity of 100 18-lb. high explosive shells a day. Henry Schaake is president.

Electrical

Southampton, Ont.—The town council contemplate spending $13,000 on the installation of a hydro-electric system.

Toronto, Ont. — The Toronto Hydro-Electric Commission will build a sub-station at the corner of Gerrard street and Carlaw avenue, to cost $60,000. Transformers and other equipment will be required.

Municipal

Bridgen, Ont.—It is proposed to increase the capacity of the electric light plant in this village.

St. Andrews, N.S.—A new pumping station will be built. The total cost, including equipment, to be $35,000.

Brigden, Ont.—Extensions to the electric light plant are contemplated. A by-law will be voted on to raise $3,500 for the purpose.

Palmerston, Ont.—The town council has signed a hydro-electric contract for 200 h.p. at $40.82, and the Commission undertakes to make connections by January 1 next.

Markham, Ont.—It is proposed to spend $20,000 on the construction and installation of a modern waterworks system. A by-law will be voted on by the ratepayers on Oct. 2.

Georgetown, Ont.—A by-law will be voted on by the ratepayers on Sept. 27 to raise $30,000 to assist by way of a bonus the Glass Garden Builders, Ltd., who propose establishing a factory here.

Orangeville, Ont.—Two by-laws have been passed by the ratepayers, one to authorize a contract with the Hydro-Electric Commission, and another to raise $33,000 to provide for a municipal distribution plant.

Chesley, Ont.—It is proposed to spend $9,000 for the purchase of portions of M. A. Halliday's electric light plant, and $13,500 to provide for the cost of an electric plant and works to transmit and distribute electric power to be supplied by the Hydro-Electric Power Commission.

Oshawa, Ont.—The ratepayers last Monday voted on and carried by a vote of 839 to 75 a by-law providing for the giving of 140 acres of land to David Maxwell, of Toronto, also guaranteeing $60,000 bonds of the company. Mr. Maxwell proposes to erect a steel plant and rolling mill on the property, valued at $350,000. He will have till the end of 1916 to perform his part of the agreement.

Stratford, Ont.—The Stratford Public Utilities Commission has awarded the contract for a standpipe to the Canadian Chicago Bridge & Iron Works at a cost of $24,800. The pipe purchased, the necessary accessories, together with the labor, will cost altogether $37,250, and with the remainder of the $50,000 to be derived by the Commission fromm the sale of debentures, two gasoline engine-driven pumps will be purchased at a cost of $8,000. Each pump is to have a capacity for pumping 1,000 Imperial gallons per minute.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Messrs. S. Ruperti and Alexsieff, care Military Atache, Russian Embassy, Washington, D.C.

General Industrial

Hamilton, Ont.—The Hamilton Cotton Co. will build an addition to their factory.

Wallaceburg, Ont.—The Wallaceburg, Ont., glass works are building an addition.

Rimouski, Que.—Price Bros. & Co. new paper mill was destroyed by fire recently. The damage is estimated at $3,000.

Montreal, Que.—C. H. Johnson & Sons Ltd., will build an addition to their factory at a cost of $3,000.

Bridgeburg, Ont.—The King Separator Co., Buffalo, N.Y., will erect a plant at Bridgeburg, for assembling parts of its Canadian product.

New Glasgow, N.S.—The Rhodes Curry Co. have the contract for building an extension to the Nova Scotia Underwear Co. factory at Eureka, N.S.

Windsor, Ont.—The Canadian Salt Co. is doubling the capacity of its plant here for the manufahture of caustic powder and bleaching powder.

Edmonton, Alta.—The Canadian Linen Fibre Co., capitalized at $3,000,000, has been organized here. It is proposed to establish a plant to take care of all the flax grown in the district. G. W. Hunt, of Calgary, is interested in the proposition.

Madoc, Ont.—The Elkhorn Lime Co., Ltd., contemplate installing a battery of four kilns for the manufacture of hydrate and bulk lime. The plant will have a capacity of sixty tons of lime per day. In connection with this industry there will also be established a barrel factory. C. W. Sharpe is president of the company.

Personal

Charles Partridge, at one time one of the proprietors of the North Sidney Foundry, North Sidney, C.B., died on Sept. 14, aged 74.

William Delahaye, the Western manager of the National Mfg. Co., of Ottawa, died suddenly in Edmonton, recently. Mr. Delahaye was born in Pembroke, Ont., 54 years ago.

G. T. Hollaway, chairman of the Ontario Nickel Commission, has been making personal inspection of refining plants in Ontario. He was at Orillia and welland last week. The whole commission during the present week visit Sudbury, where they will investigate conditions.

W. F. Angus, vice-president and managing director of Canadian Steel Foundries, has been appointed a director of the parent company, Canadian Car & Foundry, Montreal, to fill the vacancy caused by the death of M. E. Duncan. He has also been added to the executive.

J. Norwood Duffus has taken over the interest of the late Mr. Francklyn in the well known firm of S. Cunard & Co., Halifax, N.S. The business is one of, if not the oldest established in Halifax, probably in the Maritime Provinces, and represents the Cunard, Compagnie Generale and other steamship lines. They also are general agents for Lloyds.

A. W. Draeseke, of the John Bertram & Sons Co., Dundas, Ont., has been made secretary of the Engineers' Committee for Standardizing Drafting Room Practice of the various plants of the Niles-Bement-Pond Co. Carl L. Grohmann, of the Pratt & Whitney Co., was elected chairman. The other members of the committee are G. E. Greenleaf, Pond Co.; A. E. Hogrebe, Crane Dept.; Edward Wray, Bement-Niles Works; Otto Pabst, Niles Works.

Tenders

Victoria, B.C.—The City Council have for sale a quantity of contractors' equipment. Full information may be obtained from the city purchasing agent at the City Hall.

Chatham, Ont.—The city engineer, F. P. Adams, is open to receive tenders for the machinery and equipment of the Chatham electric light plant, which consists principally of gas engines and producers, and electric generators.

Mimico, Ont.—Tenders will be received until Oct. 1 for the following works: sewers and water-mains, sewage disposal works, supply of sanitary vitrified pipes, sewage pumping station. Specifications and plans may be obtained from Engineer T. Lowe, 186 King street West, Toronto.

Ste. Martine, Que.—Tenders will be received by the Municipal Council of the Parish of Ste. Martine, County of Chateauguay, up to the 4th of October next for the construction of a steel bridge, 85 feet span, on concrete abutments, at the outlet of the Beau River, in this parish, according to plans and specifications to be seen at office of the undersigned. Nap. Mallette, secretary-treasurer.

Toronto, Ont.—Tenders will be received addressed to the chairman, Board of Control, up to Tuesday, October 12, 1915, for the construction and delivery of 36-inch stop valves, valve operating mechanism and special castings, for main pumping station. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

Fort William, Ont.—Tenders addressed to the undersigned will be received until Thursday, September 30th, for heating, plumbing and electric wiring of the Registry Office, Fort William. Plans and specifications can be seen at the office of Geo. A. Eoll, Fort William, and at the Department of Public Works, Toronto. Also for the heating, plumbing and electric wiring of the jail building, Sault Ste. Marie, Ont., until October 7th. Plans and specifications can be seen on and after September 22nd in the sheriff's office, Sault Ste. Marie, and at the Department of Public Works, Toronto.

Ottawa, Ont.—Tenders will be received up to Tuesday, October the 19th, for the undermentioned items for delivery to H.M.C. Dockyards at Halifax, N.S., and Esquimalt, B.C.: Brass bars, antimony, iron firebar, brass sheets, aluminum, pig iron, brass tubes, steel angles, iron angles, copper sheet steel, boltstaves, iron boltstaves, copper tubes, steel plates, iron sheets, zinc plates, steel sheets, India rubber, lead, milled steel for tools, sheet packing, or sheet, etc. Forms of tender and all information may be obtained by application to the undersigned or to the Naval Store Officer at H.M.C. Dockyard, Halifax, N.S., or Esquimalt, B.C. Applicants for forms are requested to state definitely the item or items on which they desire to tender. G. J. Desbarats, Deputy Minister of the Naval Service.

Tenders for Scrap.—Sealed tenders for the purchase of a quantity of scrap metal at the Dominion Arsenal, Quebec, will be received up to noon of Thursday, the 23rd day of September, 1915. The quantities are approximately as follows:

	Lbs.
Brass, etc.	16,000
Charger steel	81,120
Steel, tool, lumps	13,950
Steel, mild, lumps	129,232
Turnings	72,074
Cast iron	183,848

The prices should be for delivery, ex stores, Dominion Arsenal, Quebec, material to be removed within 30 days after acceptance of tender. All the scrap is loose, and information required may be obtained from the Superintendent, Dominion Arsenal, Quebec; or Department of Militia and Defence, Ottawa.

Contracts Awarded

Cartierville, Que.—R. T. Smith & Co. have been awarded the contract for laying the intake pipe in connection with the filtration plant.

Ste. Ann's, C.B.—The Cape Breton Pulp Co. have awarded the contract to the local firm of Spurr & Israel for the rebuilding of their plant.

Winnipeg, Man.—The Ford Motor Co. have awarded the general contract for their new factory in Winnipeg to the Carter, Halls, Aldinger Co., of this city. The building will cost about $250,000.

Regina, Sask.—The James Ballantyne Co., of Montreal, have been awarded the plumbing and heating contract for the new Simpson building, and the Vulcan Ironworks Co. will do the steel work.

The Thomas Davidson Mfg. Co., of Montreal, Que., have closed a contract for the installation of a "Snyder" electric furnace, built by the Snyder Electric Furnace Co., Chicago. The furnace will melt and refine cold steel scrap, producing high-grade steel for casting into blanks for the manufacture of shells. This is the second Snyder furnace to be constructed for to produce steel for use in making war munitions. The other furnace will be installed at Sherbrooke, Que., by the Canadian Brakeshoe Co. In view of the stringent requirements with regard to war munitions, it is significant of the development of electric furnaces that they are being installed for this purpose. The Thomas Davidson Mfg. Co. are well known as makers of stamped utensils, and as tin and sheet iron metal workers, and the cuttings from their stamping department will be used, together with scrap available in the district for melting down in the "Snyder" furnace.

Wood-Working

Moncton, N.B.—Mark's Carriage Factory has been destroyed by fire, with a loss of $25,000.

Listowel, Ont.—Work has been started on the new addition to the Malcolm furniture factory. The addition will be 62 by 46 feet, three storeys high, and will be built of brick.

Send for full description, prices and our new list of New and Used Machine Tools

MARSHALL & HUSCHART MACHINERY COMPANY

17 South Jefferson Street, CHICAGO, ILL.

Uxbridge, Ont.—It is announced that a Toronto concern has taken over the old piano factory, and will make cabinets and office fixtures.

Trade Gossip

Latchford, Ont.—The new plant of the Canadian Pulp & Lumber Co., which was built on the site of the one destroyed by fire several months ago, was started last Saturday. It is the intention of the management to work night and day in order to catch up on the large stock of pulpwood now on hand.

Fort Francis, Ont.—After some two years of correspondence with the Hydro-Electric Commission at Toronto the Fort Francis Board of Trade, has succeeded in getting one of the engineers to make a special visit to inquire into the possible amount of power which could be disposed of in case Sand Island Falls should be developed.

Ball Bearing Contract.—In connection with the proposed manufacture of guns in Canada, it will be of interest to manufacturers to learn that the **Chapman Double Ball Bearing Co., Ltd.**, of Toronto, recently received an important contract for a very large number of sets of special ball bearings for a certain type of gun now being constructed.

John S. Metcalf Co., of Montreal, Chicago and London, have been awarded the contract by the Chicago and North-Western Railway Co. to act as designing and consulting engineers for that railway's new grain elevator plant at South Chicago. This plant will be operated by the Armour Grain Company, and is to be the largest and most complete grain handling and storing house yet designed by elevator engineers.

Toronto, Ont.—Over $2,000,000 has been spent on the harbor improvement work this and last year. About two hundred acres of land have been reclaimed in the Ashbridge Bay district. This is for factory sites, and is valued at $10,000 an acre. The cost of reclamation was $450,000, and the value of the land reclaimed is $2,000,000. Fifteen acres of park lands have been made for the city at Ward's Island.

The Thomas Davidson Mfg. Co., Montreal, Que., has closed a contract with the Snyder Electric Furnace Co., Chicago, for the installation of a Snyder electric furnace. This furnace will be used in melting and refining cold steel scrap, producing high-grade steel for casting into blanks for the manufacture of shells. The Thomas Davidson Company manufactures tin and sheet steel products and the cuttings from its stamping department will be used, together with scrap available in the district, for melting down in the furnace.

The Dominion Steel Foundry Co. directors announce the first dividend of 1¾ per cent. on the preferred stock. The concern is a merger of the Dominion Steel Castings Co., and the Hamilton Malleable Iron Co., with an authorized capital of $2,000,000, half common and half preferred. The stock is not listed. In 1914 the company reported a loss in operations of about $25,000, but this year war contracts have placed the finances in a secure position.

The Canada Cement Co. of Montreal, is understood to have secured large contracts for 75 mm. high explosive shells for the French and Russian Governments. The New York legal representative of the Canadian Co. has notified American firms that sub-contracts will be placed with them, and as a preliminary is asking for prices, time of delivery and capacity which each of the prospective bidders can guarantee. Each competing firm is also asked to send a representative to New York, to confer with Frank P. Jones, general manager of the Cement Company.

Steel and Radiation.—R. J. Cluffe has resigned the position of general manager followed by the resignation of H. S. Howard, the sales manager. As a result, the staff is now constituted as follows: general managing director, H. H. Macrae; assistant, T. R. S. K. Case; controller and secretary, F. J. Mayo; general sales manager, W. S. Cooke; assistant sales manager, H. O. Morris; chief heating engineer, James Wilson. Mr. Cluffe has taken over the management of his interests in Canada Pipe & Steel, and the Cluffe Manufacturing Co. Mr. Howard has been appointed to an important position with Lord & Burnham of St. Catharines, heating engineers.

Toronto Terminals Annual Meeting. — The annual meeting of the shareholders of the Toronto Terminals Railway Co. was held in the board room of the general offices of the C. P. R. in Montreal, on Sept. 14. Howard G. Kelly, president of the company, was in the chair, the other directors present being Sir Thomas Shaughnessy, Geo. Bury and I. G. Ogden. All the directors and officers were re-elected as follows:—Directors, Sir Thos. E. Shaughnessy, E. J. Chamberlin, Howard G. Kelly, George Bury, I. G. Ogden and J. E. Dalrymple. Officers, Howard G. Kelly, president; George Bury, vice-president; Henry Phillips, secretary; H. E. Suckling, treasurer; J. W. Leonard, general manager.

Demand for Brass Wire and Pins.—Manufacturers of brass pins in Birmingham and district, England, are experiencing much difficulty in producing brass wire, owing to the commandeering of supplies by the Government. The price of wire has doubled since last August, and Canadian manufacturers with surplus stocks should communicate with Birmingham buyers whose names and addresses may be obtained from the Department of Trade and Commerce, Ottawa. (Refer File No. 1362.) Manufacturers of steel and brass pins are offered more orders than their depleted staffs are able to execute. The subject may or may not be of interest to Canadian manufacturers; but conditions are so abnormal and irregular in the British commercial world that transactions quite impossible in ante-bellum days are now being conducted on a profitable basis.

Condition of Tool Market.—Workshops in the United Kingdom producing machine tools have been placed by the Government under the category of "controlled establishments" and are therefore under the control of the Munitions Department. These workshops will now be engaged in the manufacture of war requirements, and it will be interesting to watch the effect of the new conditions upon the output of tools generally, both for hand and machine use. Large quantities of mechanics' hand tools are imported in normal times, as well as certain classes of machine tools. If Canadian manufacturers will forward their catalogues to the Department of Trade and Commerce, Ottawa, every effort will be made to introduce them to importers.

New Incorporations

The Western Shells & Box Co. has been incorporated with a capital of $25,000 to carry on business at Edmonton, Alta.

The A. Schrader, Son, Inc., has been granted a provincial license at Toronto, Ont., with a capital of $40,000, to manufacture machinery apparatus and appliances of all kinds. Harold R. Cole, of Toronto, is attorney.

The Peninsular Pulp & Paper Co. has been incorporated with a capital stock of $200,000 by William E. Shafer, Edwin R. Larter, and others, of Niagara Falls, N.Y., to manufacture pulp, lumber and paper at Thorold, Ont.

The Pullman Motors, Ltd., has been incorporated at Ottawa with a capital of $100,000 to manufacture motor cars, trucks, etc., at Toronto. Incorporators, David Pullman, John E. Webb and George W. Webb, all of Toronto, Ont.

The Canadian Autopower, Ltd., has been incorporated at Toronto, with a

capital of $40,000, to manufacture power attachments for motor cars, etc., at Toronto. Incorporators—John Reid Robertson, Harold Wilson and Robert Angus, all of Toronto.

The Thompson-James Co. has been incorporated with a capital of $40,000, to manufacture explosives of every description, with head office at Toronto. Incorporators, Cecil H. Thompson, Arthur Stewart James and James R. L. Starr, all of Toronto, Ont.

The Alberta Flour Mills, Ltd., has been incorporated at Ottawa, with a capital of $5,000,000, to carry on a flour milling business, with head office at Calgary, Alta. Incorporators—Arthur T. Seyler, Thomas M. Ovens and Homer H. Farman, all of Calgary, Alta.

The Gowland Optical Co. has been incorporated at Ottawa, with a capital of $1,000,000, to manufacture optical and scientific instruments of all kinds at Montreal, Que. Incorporators—Joseph Armitage Ewing, George Samuel McFadden, and Richard B. Proctor, all of Montreal.

The Automatic Valve Company of Canada, Ltd., has been incorporated at Ottawa with a capital of $20,000 to manufacture automatic valves and other apparatus at Calgary, Alta. Incorporators—Francis W. Griffiths, Clare Montrose Wright, and L. Herson Miller, all of Calgary, Alta.

The Edmonton Power Co. has been incorporated at Ottawa, with a capital of $100,000, to carry on the business of a light, heat and power company. Head office at Montreal, Que. Incorporators—Aubrey Huntington Elder, Patrick Francis Brown, and Burton F. Bowles, all of Montreal.

Universal Measuring Devices, Ltd., has been incorporated at Ottawa, with a capital of $50,000, to acquire patents of and deal in or manufacture measuring devices and gauges, etc. Head office is in Toronto, and the incorporators are Cecil W. Stancliffe, Stanley A. Waggett, and Gerard Ruel, all of Toronto.

Catalogues

The Wentworth Institute, Boston, Mass., has issued a syllabus for 1915-1916, covering the one-year and two-year courses, also the evening shop and technical courses. A number of illustrations show interior views of laboratories and class rooms, etc.

The Mesta Machine Co., Pittsburgh, Pa., have issued bulletin "Ka," containing a horse-power chart for gears and pulleys. The chart may be used for determining the variables for rotating parts transmitting power, such as gears, pulleys, rope wheels, etc. Full particulars regarding this chart may be obtained by writing the company.

Furnaces.—The Monarch Engineering & Mfg. Co., Baltimore, Md., have issued a series of bulletins illustrating and describing some of their products, which include portable "Simplex" melting furnaces, tool room furnaces, core ovens, oil burners, etc. Full particulars are given of each type of equipment, and tables give the principal dimensions and capacities, etc., for each size. The bulletins are fully illustrated.

Fabroil Gears.—Bulletin No. 48703, issued by the Canadian General Electric Co., Toronto, illustrates and describes in detail the construction of "Fabroil" gears, which are applicable to numberless types of machine shop tools, such as lathes, planers, drill presses, etc. They are also well adapted for use on back-geared motors. The bulletin contains complete dimension tables for standard construction "Fabroil" gears for the

various diametral pitches which are accompanied by diagrams. Velocity and horse-power tables are included, also some interesting data on the selection of gears, with a number of tooth profiles. One page contains several useful formulae for gear calculations.

Use and Abuse of Ball and Roller Bearings is the title of a new twenty-page treatise by F. J. Jarosch, chief engineer of the Bearings Company of America. The text gives explanations and experiences which help in the selection, mounting and lubrication of ball and roller bearings in automobile gears and in all other rotating parts and is intended to help in detecting the real cause of trouble. Nineteen drawings are used to illustrate the text matter. Mr. Jarosch contributes in a very practical way, valuable thoughts to a much discussed subject, and automobile engineers as well as many others who are interested in the subject will be glad to know that a copy of this treatise may be obtained free upon request from the publishers, the Joseph Dixon Crucible Co., Jersey City, N.J.

Book Reviews

Bank Map of Ontario and Quebec.—A striking illustration of the financial progress throughout the two older provinces of the Dominion during recent years, with respect to banking facilities, is graphically shown in a new edition of a bank map of Ontario and Quebec which has been issued by the Department of the Interior at Ottawa. According to the information which has been incorporated in the publication, the number of branches in operation in 1901, the first year for which statistics of this nature are given, totalled approximately 500, in comparison with 2,000 at the present time. This interesting compilation of current banking information is valuable also as a railway map, showing as it does, the location, on the various main and branch lines, of all towns and cities. This, together with other general information, makes the publication very useful for reference purposes. A copy may be procured free of charge upon application to F. C. C. Lynch, Superintendent of the Railway Lands Branch, Department of the Interior, Ottawa.

Wind Stresses in Steel Frames of Office Buildings, by W. M. Wilson and G. A. Maney, has just been issued as Bulletin No. 80 of the Engineering Experimental Station of the University of Illinois. This bulletin is a mathematical analysis of the stresses in the steel frames of office buildings due to the

wind load on the building. It is the most extensive study of the subject which has appeared. The steel frames of office buildings resist the horizontal shear due to wind by virtue of the stiffness of the columns and girders. The sum of the moments at the tops and the bottoms of all of the columns in a story is equal to the total shear on the story multiplied by the story height. The distribution of this moment depends not only upon the relative stiffness of the columns but also upon the relative stiffness of the girders which connect the columns. Further, the distribution of the moment in one story depends not only upon the size of the members in that story but also upon the size of the members in the adjacent stories. General equations are derived which can be used to determine the wind stresses in both symmetrical and unsymmetrical bents from one to five spans wide and any number of stories high. These equations are used to determine the numerical values of the moments, shears and direct stresses in a symmetrical three-span bent twenty stories high. The method of determining these stresses presented in the bulletin is called the "Slope-Deflection" method. It is mathematically exact except for the assumptions upon which it is based. In the discussion of the assumptions the fact is brought out that while the assumptions are not exactly true, the errors do not materially affect the results. Four approximate methods are presented which are in use. The moments are determined in a number of bents having different proportions, by these approximate methods and by the slope-deflection method. This comparison shows that two of the approximate methods are so inaccurate that they should never be used. The other two approximate methods are quite accurate when applied to certain bents but when applied to other bents they may give results which are seriously in error. A new approximate method is presented which agrees with the slope-deflection method except where there are large changes in the size of the columns and girders. A model of a bent cut from a sheet of celluloid was subjected to a known shear. The deflection of the columns and the changes in the slope of the elastic curve at the ends of the girder as measured, and as computed by the slope-deflection method agreed very closely. The slope-deflection method can be used in the design of buildings but it has its greatest value as a standard for determining the accuracy of approximate methods. Copies of Bulletin No. 80 may be obtained from the European agent, Chapman and Hall, Ltd., 11 Henrietta St., Covent Garden, London, England.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Mount Brydges, Ont.—The Crow Motor Co. plans a factory to manufacture automobile motors, to cost $10,000.

Medicine Hat, Alta.—The Medicine Hat Pump & Brass Mfg. Co. is in the market for three new lathes, 14 to 18 in., for immediate delivery.

Eustis, Que.—The Eustis Mining Co. will rebuild their mill, which was recently destroyed by fire. The cost is estimated at about $85,000.

Electrical

St. Hilaire, Que.—The Century Electric Co., of Montreal, will install an electrical transmission system for the town.

Weston, Ont.—Etobicoke township has agreed to all the conditions laid down by the Weston Hydro-Electric Commission for the lighting of Thistleton, and the work is to go on at once.

Chesley, Ont.—The ratepayers last Monday voted in favor of the Hydro bylaw, which passed by a large majority. The power will be turned on about Christmas, and it will come from Eugenia Falls.

Toronto, Ont.—Arrangements have been made between the Mimico Power Co. and the Etobicoke Township Council which will result in the extending of the system to Humber Bay. At a cost of about $1,500, a line will be run along George and Church Streets, following the request of the citizens who desire to become Hydro customers.

London, Ont.—Work on the new street lighting system which the utilities board will give to the city out of its surplus funds has already commenced, and it is expected that the 2,400 new lamps will be installed in the course of about six months. General Manager Buchanan states that the new lights will be 150 c.p. instead of 75, as at present.

Municipal

Verdun, Que.—The council have decided to make an extension to the 36-in. intake pipe.

Cranton, Ont.—The town council proposes to install a hydro-electric system at a cost of $5,000.

Owen Sound, Ont.—The town council contemplate making extensions to the waterworks system.

Petrolea, Ont.—The town council will take over the Petrolea Utilities Co. power plant at $15,000.

Crediton, Ont.—The council contemplates the installation of a power distribution and lighting system.

Perth, Ont.—The Canadian Electric and Water Power Co. are in the market for cast iron pipes and specials.

EQUIPMENT FOR AUSTRALIAN RAILWAYS.

Tender forms, specifications and drawings have been forwarded by Commissioner D. H. Ross, Melbourne, for equipment required by the Victorian and Queensland Government Railways. These tender forms will be open to the inspection of Canadian manufacturers when received at the Department of Trade and Commerce, Ottawa (refer File No. 1435). Particulars of the requirements, together with the date on which the tenders close at Melbourne are briefly outlined thus:—

Victorian Railways.

No. 29,410. November 24.—2 duplex boiler feed pumps as specified.

No. 29,421. November 24.—750 sq. yds. compressed felt as specified.

Queensland Railways.

Tenders close at the office of the Queensland Railways, Brisbane, on November 2, 1915, for 10—30,000 gallons conical wrought iron tanks.

The departure of mails from Vancouver are indicated thus:

From Vancouver, October 27, due at Melbourne on November 20.

Rosthern, Sask.—The town council will call for tenders shortly for the supply of a fire engine, hose, etc.

Ridgetown, Ont.—It is proposed to install an ornamental street lighting system here in connection with the new hydro system.

Port Dover, Ont.—The town council have decided to build a new pumping plant. James St. Pierre, Bear Line, Ont., is the commissioner.

Owen Sound, Ont.—The town council have authorized a $16,000 debenture issue to cover the cost of waterworks extensions. Cast iron pipe will be required.

Dorchester, Ont.—The construction of gas mains and connections in this town is being considered by the Southern Ontario Gas Co., St. Thomas, Ont. F. B. Tomb, London, is manager.

Markham, Ont.—Property owners, by a majority of 49, last Monday, voted in favor of the plan of waterworks extension drawn up by Engineer E. A. James. The cost of the work is about $20,000.

Lumsden, Ont.—The town council are negotiating with the local electric light company to purchase the plant in operation here. The question will be referred to the ratepayers before the deal is completed.

Hamilton, Ont.—Preliminary steps have been taken by the Board of Control to spend $35,000 on draining of all the low-lying territory in the north-east end of the city, below the Jockey Club ground.

Windsor, Ont.—If the recommendation made by the fire committee is approved by the city council, apparatus of a total value of $11,000 will be added to the equipment of the fire department. Tenders will shortly be asked for the contract of supplying Windsor with a new tractor and motor service truck.

Port Colborne, Ont.—A by-law to authorize an agreement with the Ontario Power Co. of Niagara Falls, Ont., to supply power to Port Colborne and Humberstone for a term of five years, was voted on recently and carried in Port Colborne, 124 for and 59 against, and at Humberstone 104 for and 7 against.

St. Catharines, Ont.—The ratepayers on September 21, by an almost unanimous vote carried a by-law granting a franchise for 20 years to the Relief Gas Co., which will supply natural gas wholesale to the municipal system. The city purchases the gas at 25 cents per thousand feet, and will distribute it to consumers at an estimated cost of 35 cents per thousand feet.

Sarnia, Ont.—A recommendation that the City Council negotiate for the purchase of the present electrical plant for $192,000, and submit a by-law to the

JOHNS-MANVILLE SERVICE COVERS THE CONTINENT

JOHNS-MANVILLE SERVICE TO THE MANUFACTURER

THIS Emblem is rapidly becoming one of the most widely known trade-marks on this continent; but even though it belted the earth, it could not stand more staunchly than it does to-day for the business principles underlying J-M Responsibility.

J-M Ferro Compound saves many a casting from the scrap pile and cuts down re-melting costs

J-M Ferro Compound makes many a casting, big or little, fit to send out that would otherwise be scrapped and melted for re-casting on account of blow-holes, sand holes, etc.

J-M Ferro Compound is a chemical iron cement that becomes, when dry, a part of the casting itself and so acts as a permanent repair.

It fills up sand holes and other defects permanently. It cannot dry up and fall out.

J-M Ferro Compound is mixed with water, applied with a trowel and hardens in a few hours. It can then be finished with a file or emery wheel, and as it is the same color as the casting, its presence can never be detected.

Its cost per casting is insignificant, but the sum of its savings is an important item in every foundry or machine shop business.

Ask our Nearest Branch for Descriptive Literature of Applications, Uses, etc., and let us Quote You Prices and Discounts.

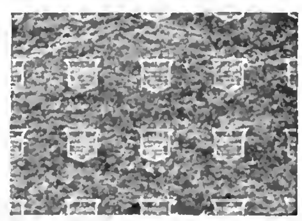
J-M Permanite—the Packing that has won its way on performance

J-M Permanite is a handy sheet because it is equally efficient on wet or dry joints. It has no respect for temperature or pressure, nor is it affected by ammonia, acids or alkali.

Then, too, it stays where it's put. It does not compress under any stress; in fact it expands under working conditions, making tight joints tighter.

J-M Permanite is very light in weight. When the J-M Salesman suggests J-M Permanite, say, "I'll try it once."

We are willing to let it convince you on the job.



J-M Permanite

The Canadian H. W. Johns-Manville Co., Ltd.

TORONTO MONTREAL WINNIPEG VANCOUVER

199

ratepayers regarding the immediate installation of hydro was made at a special meeting of the council on September 22 by Messrs. J. J. Jeffery and L. F. Jeffery, engineers, of Toronto. The council decided to act on the advice and will take definite action at the next meeting.

General Industrial

Brantford, Ont.—The Concrete Post Co. has secured a site at Winnipeg, Man., and will erect a factory.

Georgetown, Ont.—The Glass Garden Builders propose establishing a factory here for building greenhouses, etc.

Wallaceburg, Ont.—An addition is being built to the Wallaceburg Cut Glass Works. A. Gregory, Dresden, Ont., is the contractor.

Renfrew, Ont.—Fire, on September 26, destroyed the flour mill at Pakenham owned and operated by the Renfrew Flour Mills Co. The mill, which was a stone structure and modern in every way, was totally destroyed. The elevator and office was also burned.

Woodstock, N.B.—Representatives of the Potato Products Co., of Belleville, Ont., have been looking over the ground in connection with the establishment of a business for the manufacture of starch, potato flour and dried potatoes. R. G. Graham, of Belleville, is the head of the business.

Wallaceburg, Ont.—The Dominion Sugar Co. is ready to start the erection of a million-dollar sugar factory in Chatham, and the only thing that is holding them up is the question of getting two railway spurs into their property, one from the Grand Trunk and the other from the C. P. R.

Tenders

The Pas, Man.—Tenders will be received up to October 5 for the supply and delivery of cast iron or steel water pipe and specials, also fire hydrants and valves. Particulars may be obtained from the resident engineer's office, or from Murphy & Underwood, engineers, Saskatoon, Sask.

St. Lambert, Que.—Tenders will be received up to October 4, 1915, for the installation of 42 lamp standards complete with about 6,500 feet of duplex underground cable terminals, etc. Plans may be seen, specifications and tender form had on application at the office of town engineer E. D. Drinkwater.

Orillia, Ont.—Tenders will be received until October 7 for miscellaneous iron work, heating, plumbing and electric wiring in connection with the rebuilding of the Municipal Buildings. Particulars may be obtained from the town clerk, Orillia, or from the architects, Burke, Horwood & White, Toronto.

Toronto, Ont.—Tenders will be received, addressed to the chairman, Board of Control, up to Tuesday, October 12, 1915, for the construction and delivery of 36-inch stop valves, valve operating mechanism and special castings, for main pumping station. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

Ste. Martine, Que.—Tenders will be received by the Municipal Council of the Parish of Ste. Martine, County of Chateauguay, up to the 4th of October next for the construction of a steel bridge, 85 feet span, on concrete abutments, at the outlet of the Beau River, in this parish, according to plans and specifications to be seen at office of the undersigned. Nap. Mallette, secretary-treasurer.

Ottawa, Ont.—Tenders will be received until Tuesday, September 28, 1915, for one (1) motor generator set, one (1) induction motor, three (3) power transformers and switchboard apparatus to be delivered at the Government Printing Bureau, Ottawa, Ont. Specification and forms of contract can be seen and forms of tender obtained at the Department of Public Works and at the offices of Thos. Hastings, clerk of works, Postal Station "F," Toronto, Ont., and R. L. Deschamps, Superintendent of Public Buildings, Montreal, Que.

Toronto, Ont.—Tenders, addressed to the secretary-treasurer of the Board of Education, will be received until Friday, October 1st, 1915, for temperature regulators, sundry schools; cabinet work, including work benches, tables, cupboards, etc., for manual training and domestic science centres; concrete retaining wall, Roden School; local telephones, sundry schools; electrical work for science rooms, Harbord Street and Malvern Avenue Collegiate Institutes. Specifications may be seen and all information obtained at the office of the Superintendent of Buildings, City Hall, Toronto.

Ottawa, Ont.—Tenders will be received up to Tuesday, October the 19th, for the undermentioned items for delivery to H.M.C. Dockyards at Halifax, N.S., and Esquimalt, B.C.: Brass bars, antimony, iron firebar, brass sheets, aluminum, pig iron, brass tubes, steel angles, iron angles, copper sheet, steel boltstaves, iron boltstaves, copper tubes, steel plates, iron sheets, zinc plates, steel sheets, India rubber, lead, milled steel for tools, sheet packing, or sheet, etc. Forms of tender and all information may be obtained by application to the

undersigned, or to the Naval Store Officer at H.M.C. Dockyard, Halifax, N.S., or Esquimalt, B.C. Applicants for forms are requested to state definitely the item or items on which they desire to tender. G. J. Desbarats, Deputy Minister of the Naval Service.

Trade Gossip

The Canadian Malleable and Steel Range Mfg. Co. has increased the capital stock of the company to $350,000.

Phosphate of Lime.—Officials of the Conservation Commission report the discovery of extensive deposits of phosphate of lime in the National Park at Banff. The importance of the discovery to the agricultural industry of the West will be great, as phosphate of lime is of value in maintaining the fertility of the soil.

Big Orders from Italy.—A contract for 100,000 pairs of blankets and 600,000 woollen shirts has been placed with Canadian mills by the Italian Government Commission in London. The Dominion Department of Trade and Commerce has assumed responsibility for the inspection of the goods. Representatives of Canadian firms sent to London secured the orders, which approximate one million dollars.

Antimony Mine at Lake George.—There is a prospect of the early re-opening of the antimony mines at Lake George, York County, N.B. These mines have not been opened since 1909, owing to the low price of the ore. With an appreciable increase in ore prices, a proposal has been made by a syndicate to lease the mines for a term of years. The company have also under consideration an offer of sale.

Grain Moving East.—A despatch from Fort William, Ont., states that grain shipments from the West approximate 1,200 cars for the past few days, and none of the elevators have yet been forced to run full capacity. The railroads expect the receipts to increase until about October 10, when indications are that upwards of 2,500 cars will be received daily. Lake shipments, so far, have been small, but steamship men here are confident that the Canadian fleet will be capable, or nearly so, of handling the grain from Fort William as fast as the Eastern elevators can receive it. Many of the steamships which were chartered by the Canada Steamship Lines and other companies last spring for the Atlantic Coast trade are being returned to the lakes.

Regina C.M.A.—The manufacturers' committee of the Regina Board of Trade Council has been instructed to investigate and report on the advisability of organizing a Regina Manufacturers' Association and seek affiliation with the Canadian Manufacturers' Association.

The Tate-Jones Co., Inc., of Pittsburg, Pa., have received the contract for the large new heat treating plant to be erected at the Toronto factory of the Chapman Double Ball Bearing Co. The work, which has been rendered necessary by the greatly increased demand for ball bearings, includes large capacity oil-fired furnaces of the latest type, with complete equipment of oil storage, tank pumps, etc. **The Rudel Belnap Machinery Co.** of Toronto are Canadian representatives for Tate-Jones Co., Inc.

Oshawa Railway Co.—The annual meetings of the Thousand Islands Railway Co. and the Oshawa Railway Co. were held at Deseronto, Ont., on Monday, September 13, 1915, at which meetting the following directors were elected: E. Walter Rathbun, Deseronto; H. W. Cooper, Gananoque; J. H. ValLeau, Gananoque; B. R. Hepburn, Picton; D. A. Valleau, Oshawa.

Personal

W. J. Gage, of Toronto, has donated $10,000 to the Government for the purpose of buying an armored biplane.

Sir Lyman Melvin Jones, president of the Massey-Harris Co., Toronto, is in the West inspecting the company's Western agencies.

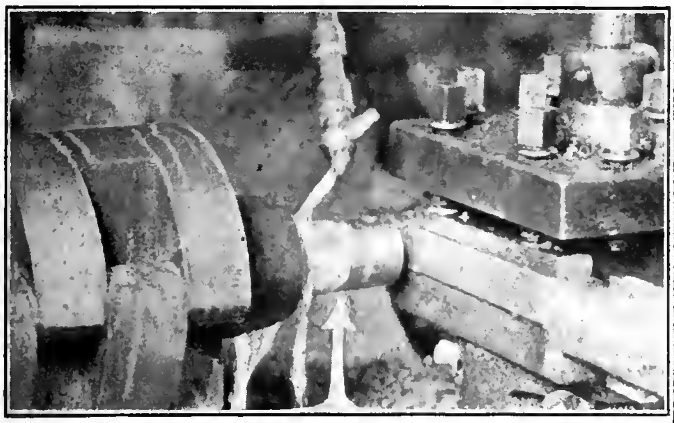
Sarnia, Ont.—From now until the close of navigation Capt. Foote will sail the steamer Hamonic, and Capt. Campbell will sail the Huronic, while Capt. Wright will remain ashore and perform the duties of shore captain.

Walter F. Wright, manager of motor sales, Canadian General Electric Co., Toronto, has resigned to accept a position as Ontario manager for the Eugene F. Phillips Electrical Works. Mr. Wright's headquarters will be in Toronto.

R. B. Larmour, assistant general freight agent of the C. P. R. at Vancouver, B.C., has been appointed to succeed the late W. F. Stevenson, of New York as general agent of the C. P. R. freight department, New York City.

Collingwood Schreiber, C.M.G. general consulting engineer of the Department of Railways and Canals, and L. K. Jones, Assistant Deputy Minister, are leaving on a semi-annual inspection trip through the West, and will go as far as Prince Rupert, the terminus of the G. T. P.

The A. R. Williams Machinery Co., Toronto, have a booth at the American Foundrymen's Convention and Exhibi-



ECONOMIC WATER OIL

SHELL MANUFACTURERS use ECONOMIC WATER OIL for METAL CUTTING of every description; it will not gum nor rust, and it SAVES TIME AND LABOR.

WE CAN SAVE YOU 50% in the **COST** of your **CUTTING MIXTURE** BECAUSE

ONE GALLON of ECONOMIC WATER OIL will mix readily with **30 to 50** gallons of WATER, making a thick, creamy emulsion, and giving you a cutting mixture which will not only be **satisfactory**, but will produce very **ECONOMIC RESULTS.**

tion at Atlantic City, Pa. T. C. McDonald is in charge of the exhibit, which consists of literature and other matter dealing with shell making machinery. It was the intention of the company to have an exhibit of machine tools, but the idea had to be abandoned on account of the difficulty in obtaining the tools.

New Incorporations

Leek & Co., Ltd., Vancouver, B.C., has been incorporated with a capital stock of $100,000 to manufacture electrical goods, machinery, iron, steel, etc.

The Specialty Paper Bag Co. has been incorporated at Ottawa with a capital of $100,000 to manufacture jute, cotton, paper and all other kinds of bags at Ottawa. Incorporators: Irving Wells Smith, Gerald Morphy Malone, of Toronto.

The Lindsay Factories, Ltd., has been incorporated at Toronto with a capital of $50,000 to do a general manufacturing business with head office at Toronto. Provisional directors are G. E. Lindsay, S. W. Burns and Thomas W. Horn, all of Toronto.

The Electric Zinc Co., Ltd., has been incorporated at Ottawa with a capital of $24,000 to operate zinc smelters and refineries at Sherbrooke, Que. Incorporators: Leland Drew Adams and Charles Herbert May, of Oakland, Cal., and John P. Wells, of Sherbrooke, Que.

The A. T. Wattie Cold Storage Co., Ltd., has been incorporated at Toronto with a capital of $40,000 to carry on a cold storage business at Bracebridge, Ont. The provisional directors are John E. Wattie, Mervyn L. Watt and Ernest Green, all of Bracebridge, Ont.

The Orillia Molybdenum Co., Ltd., has been incorporated at Toronto with a capital of $200,000 to acquire and develop mineral lands and deposits. Head office at Orillia, Ont. Provisional directors are R. C. Dunbar, John E. Tudhope and J. Fraser Tudhope, all of Orillia, Ont.

The Russell Natural Gas & Oil Co., Ltd., has been incorporated at Ottawa with a capital of $1,000,000 to carry on the business of producing and refining petroleum products and natural gas, at Ottawa, Ont. Incorporators: Orlando Arthur Letts, John George Hackland, all of Ottawa, Ont.

The Harris Heating & Engineering Co., Ltd., has been incorporated at Ottawa with a capital of $25,000 to carry on the business of mechanical engineers, founders, smiths, etc., at Montreal, Que. Incorporators: Joseph Albert Harris, Avila Mayer and Louis A. Desy, all of Montreal, Que.

The Sorel Steel Foundries Co., Ltd., has been incorporated at Ottawa with a capital of $100,000 to acquire and take over as a going concern the business now carried on at Sorel, Que., by Beauchemin & Fils, Ltd. Incorporators: Louis Philippe Tremblay and Napoleon Latraverse of Sorel, Que.

The Canadian Cartridge Co., Ltd., has been incorporated at Toronto with a capital of $400,000 to manufacture copper, brass and steel products, also cartridges and shells, etc. Head office at Toronto. Provisional directors are William S. Morlock, Bruce McKinnon and Roy B. Whitehead, all of Toronto

Railways—Bridges

Owen Sound, Ont.—The Grand Trunk will rebuild a large section of the wharf fronting on their property during the coming winter. Local contractors are being asked for tenders on the work, which will probably run as high as $10,000.

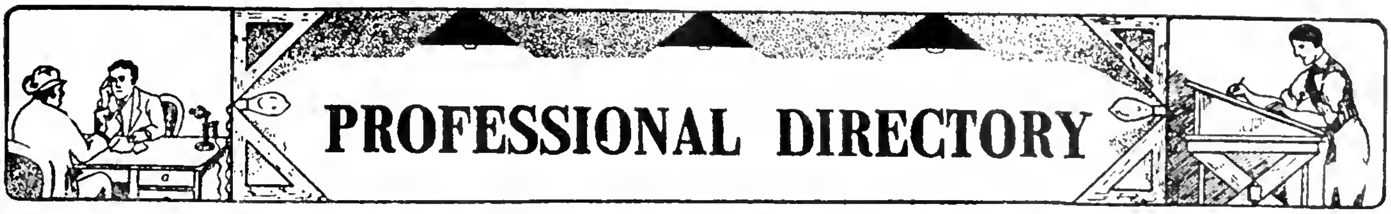
Weston, Ont.—Engineers of the Toronto Suburban Railway Co. have surveyed an extension of the radial line from Woodbridge to Kleinburg. Another branch line of the Weston division has been surveyed east of Weston and connects with the Davenport line at Davenport station.

Edmonton, Alta.—J. D. McArthur, president of the Dunvegan and Waterways Railways, states that steel laying will begin on the Waterways Railways by the end of September. The condition of the grading work is such that steel will be laid continuously until McMurray is reached, probably by the end of the year.

Cobourg, Ont.—Several municipalities in the counties of Northumberland and Durham are petitioning the Ontario Hydro-Electric Commission to make a report on the advisability of constructing electric railways from Peterboro and Campbellford to Cobourg, passing through the municipalities interested. Such roads would open a teritory now devoid of railway facilities, especially the northern part of Northumberland County.

Contracts Awarded

Toronto, Ont.—The National Regulator Co. has been awarded a contract for heat regulating apparatus for the Gledhill Avenue School.



PROFESSIONAL DIRECTORY

Building Notes

Hamilton, Ont.—The T. Eaton Co. has secured a permit to build a $110,000 factory here.

Saskatoon, Sask.—MacDonald-Crawford, Ltd., propose building a warehouse here to cost $50,000.

Ottawa, Ont.—The Bate Realty Co. will build an addition to their warehouse at a cost of $25,000.

Markham, Ont.—The Bank of Nova Scotia will at once begin the erection of a substantial brick structure on Main Street.

Toronto, Ont.—The Board of Education has obtained a building permit for a new school on Bartlett Avenue, to cost $52,900.

Clayton, Ont.—It is proposed to build a summer hotel here to cost $400,000. F. A. Wright, of New York, has prepared the plans.

Toronto, Ont.—The Toronto Pharmacal Co., has applied for a permit to erect a $7,000 addition to their factory on Brockton avenue.

Toronto, Ont.—A new school building will be erected at Fairbank, in York township. Edwards & Saunders, of Toronto, are the architects.

Toronto, Ont.—McGregor & McIntyre have obtained a building permit from the city architect's department for the erection of a two-storey brick factory, costing $8,700, at 1139 Shaw Street.

Toronto, Ont.—The C. P. R. has secured a permit from the city architect for the erection of the new North Toronto station, to be built of brick and stone, and to cost $125,000. It is to be a one-storey structure.

Catalogues

Split Pulleys.—The "National" All-Steel Split Pulleys are illustrated and described in a bulletin issued by Patten Co., of Chicago, Ill.

Electric Grinder. — The Hamilton-Beach portable electric grinder for grinding dies, reamers, cutters, etc., is the subject of a bulletin issued by the Canadian General Electric Co., Toronto. A description is given of the grinder, which is accompanied by illustrations showing the grinder in operation on different kinds of work.

A Chain of Evidence.—Publication No. 14 contains a number of illustrations of large power drives where Morse chains are used, accompanied by details of each. Other matter included deals with the Morse silent chain and the

Canadian Westinghouse Company, Limited
HAMILTON, ONTARIO

FOR SALE

One new Holden-Morgan Thread Milling Machine for threading base 4.5 shells. Surplus, ordered in error.

Immediate delivery from stock. Price $650 F.O.B. St. John.

T. McAVITY & SONS, Ltd.
ST. JOHN, N.B., CANADA

"Rocker-Joint" construction. Copies of this publication may be obtained from the Morse Chain Co., Ithaca, N.Y.

"Burd Ring Wisdom" is the title of the new house organ which will be published at frequent intervals by the Burd Compression Ring Co., Rockford, Ill., the purpose being to place before those who have a desire to know the latest and most important findings in piston ring development. The first number has made a good start, and its friends will wish it success in the future.

The Westinghouse Electric & Manufacturing Co., Pittsburgh, Pa., has recently issued Leaflets 3,805, 3,806, and 3,807 on the application of automatic control apparatus to cranes and steel mills. They show the scheme of main connections and describe the method of operation of the magnetic unit switches, as arranged for the severe service of steel mill practice.

"Aqualene" is the title of a bulletin issued by the Crescent Oil Co., New York. Aqualene is a cutting lubricant for automatics, turret lathes and other tools. The bulletin describes the qualities and principal features of this lubricant, and contains a number of illustrations showing the various classes of work for which it is being used. An interesting feature is the data on production and cutting speeds, etc.

Portable Tools.—The Stow Mfg. Co., Binghampton, N.Y., are mailing to the trade copies of bulletin No. 400, illustrating and describing a complete line of "Stow" portable tools. These tools are furnished with both belt and motor drive, a feature in some cases being a "Stow" flexible shaft combination. The various lines which are illustrated are accompanied by a brief description covering the principal features and demonstrate the utility of the Stow flexible shaft.

"Finding and Stopping Waste in Modern Boiler Rooms by the use of Cochrane Meters," is the title of a catalogue which has been issued by the Harrison Safety Boiler Works, Philadelphia, Pa. The catalogue deals with the "Cochrane" appliances for accurately measuring and recording boiler feed, condensate, blow off, heating returns, cooling water, etc. The appliances include metering heaters, independent meters, precision meters and metering hot wells. The subject of stopping boiler wastes is treated in a scientific and at the same time a practical manner. The catalogue explains how this can be successfully accomplished by means of the various apparatus, described. The halftones are exceptionally clear and in-

Pattern Manufacturers, Etc.

clude views of numerous installations in addition to several cross sections showing the general construction of the appliances and method of operation. This catalogue is well gotten up. It contains 62 pages of matter printed in clear type and is bound in attractive covers. Copies of this catalogue may be obtained on application to the Canadian Allis-Chalmers, Ltd., Toronto, Ont., who are the exclusive agents for Canada.

Turret Lathes.—Catalogue J-7, issued by the Gisholt Machine Co., Madison, Wis., illustrates and describes the standard "Gisholt" turret lathe. The introduction briefly describes the range of work covered by these machines. Following is a general description of the standard turret lathes, in the form of a specification in which the principal parts of the lathe are discussed. A half-tone engraving of the standard machine with weights and dimensions covering all sizes, are found on pages 8 and 9. Motor-driven lathes are described and illustrated on pages 10 and 11, while page 12 contains particulars and views of standard boring and turning tools, being a new design of standard tool equipment. Bar tools, facing heads and accessories are shown on pages 13 and 14, while the full-swing wing rest is described on page 15. Following are several pages devoted to cuts, showing various operations on "Gisholt" lathes, and a variety of parts which have been finished on these machines. A number of half-tones show "Gisholt" lathes installed in various shops.

The A. R. Williams Machinery Co., Toronto, Ont., have recently issued a new catalogue, No. 40, dealing with machinery and tools, mill and railroad supplies. The catalogue contains 782 pages, is bound in cloth covers and is fully indexed, having in addition an index to figure numbers. The large number of lines listed precludes mention of any particular product, but it is sufficient to say that a full line of machinery and supplies for various trades is illustrated and the essential particulars given for each. The compilation of this catalogue has entailed considerable work owing to the great amount of detail involved in the preparation of the price lists and arrangement of the illustrations. This is a most useful book of reference and should be in the hands of all managers, superintendents and purchasing agents. The cuts are very clear and the press-work generally of a high order. Copies of this catalogue will be sent to responsible persons on request.

Book Reviews

"**Buoys, Beacons, and Day Marks,** and other aids to navigation on the Pacific Coast of the Dominion of Canada," is the title of a publication issued by the Department of Marine and Fisheries, Ottawa. This is the fourth edition of a list of buoys, etc., which gives the exact location of each, also description and remarks arranged in tabulated form. A copy of this list will be sent free to any shipmaster on application to the chief engineer of the Department at Ottawa, or agent of the Department at Victoria, B. C.

United States Mining Statutes Annotated, by J. W. Thompson. 1915. 1,772 pp. In two parts. Cloth. Not sold separately, $2.50. The Bulletin No. 94 is intended for persons engaged in mining enterprises that come within the scope of the Federal mining laws, and as a guide in the determination of mining rights and duties. It shows the status of every Federal mining law, both laws relating to metal mining and those relating to coal, oil, and phosphate, and to mining on public, Indian, and railroad lands. It includes references to Alaska and the Philippine Islands, and is the only complete work in its field. Owing to the expense involved in the preparation and publication of this bulletin and the limited printing funds available for the use of the Bureau of Mines, it has been necessary to place a price of $2.50 on the work. Orders should not be sent to the Bureau of Mines, but should be addressed to the Superintendent of Documents, Government Printing Office, Washington, D.C.

HOW TO KEEP MEN IN YOUR EMPLOY—A POSSIBLE SOLUTION

(Continued from page 334)

have avoided all suggestion of paternalistic motives. The work has been from the men to the company, not from the company to the men. If anything new is to be introduced, we get hold of the leaders—those men whose intelligence is most developed. Having gained their favor, the less thoughtful will fall in line.

Importance of the Foreman

In our organization, we have paid particular attention to selecting the foremen. You cannot have an unintelligent head of a department, and expect the men to be up to standard. In hiring men, a well defined policy is adopted. This policy is known to the heads of departments and thoroughly understood in the employment office. It requires cer-

tain standards and no man is sent to a department who does not fulfill these requirements. The rest lies with the foreman.

Employes are encouraged to work out their own problems, and are largely instrumental in developing the conditions under which they work. As an example, a mutual aid association was organized 20 years ago, but for 15 years it was a failure. The officers were company officials and the men showed little interest. Each year there was a deficit which the company has to meet. The promise to pay half the dues, did not induce the men to join.

The association was reorganized and its success or failure put up to the men themselves. A new management was elected. At the end of the first year, the membership had increased more than 300 per cent., and $2,000 were in the treasury. The record has been maintained each year.

The Restaurant

The next feature was a restaurant. At the suggestion of the men, a small lunch counter was established about five years ago. It was well patronized and in a few months was moved to larger quarters. It has been moved to larger quarters on three different occasions. We now have a completely equipped restaurant serving 600 daily, and this will be doubled shortly.

Everything sells for three cents, except meat, which is four cents. Nevertheless, we have saved enough to pay for the equipment for which the company advanced $8,000. The food is excellent and for 15 to 20 cents a good-sized meal is secured.

Three years ago, we started to sell small quantities of sugar, coffee, flour, tobacco, etc., in the restaurant. Since that time, this department has become a large co-operative store, doing $10,000 to $12,000 business each month. All kinds of groceries, meats, boots, shoes, rough clothing, etc., are handled. Last year, through the store, 35 carloads of coal, 20 carloads of potatoes and five carloads of apples were sold at a large saving to employes.

Two years ago a bakery was started which now bakes 3,000 loaves per day. Everything used in the restaurant comes from this bakery. A lard rendering plant furnishes employes lard at 5 to 6 cents a pound less than other stores. An ice cream factory sells a large dish of ice cream, made from cream from our own dairy farm, for 3 cents per dish. Bread sells at 4 cents, for a loaf 2 ounces larger than the usual size. In the shoe department, $3.50 and $4.50 shoes sell for $2.50 and $3. Employes save from $3 to $12 per month per family on goods purchased.

Building and Loan Association

Three years ago, our employes organized a building and loan association. Since that time, business totaling over $200,000 has been done. The assets are over $100,000 and 73 employes have bought and built homes. A dividend of 5 per cent. has been paid each year. Money is loaned at 5½ per cent. There are more than 700 stock and savings accounts with employes.

These activities are fostered and encouraged by the company, but the management and organization is carried on entirely by committees of shop men. The company advanced the money, but almost all of it has been paid back by the employes.

No reason exists why any business concern cannot put the question of handling men and their welfare on a business basis and frankly state the business reason for such an undertaking. Our employes distinctly understand that anything the company fosters for their benefit is based upon the belief that it will bring returns in dollars to both. The employes have learned that capital and labor are interdependent—that both must prosper on the same basis. They are learning that demagogues and agitators do not fill pay envelopes and never will.

The Chevrolet Motor Co. of Canada, Ltd. has been incorporated at Ottawa, with a capital of $500,000, to manufacture automobiles, etc., at Toronto. Incorporators, Harry Horsman, George Edmund Wooldridge, both of Toronto, Ont.

Wood-Working

Montreal, Que.—A fire on September 28 did about $15,000 damage to the G. H. Randall Co. furniture factory.

Montreal, Que.—The sash and door factory of Benoit Sons, on St. Timothe Street, was destroyed by fire on Sept. 25.

Cache Bay, Ont.—Geo. Gordon & Co. are building a new mill, and will require woodworking machinery .

Cache Bay, Ont.—George Gordon & Co., Ltd., will rebuild its sawmill, recently destroyed by fire, at a cost of $75,000. Alexander Trottier is in charge.

Vancouver.—The sawmill and buildings of the British Canadian Lumber Co., at New Westminster, have been sold for $1,000,000 to Leonard Imboden.

Fredericton, N.B.—Donald Fraser & Sons, of this place, have purchased a property at Nelson, on the Miramichi, and will build a lumber mill at a cost of $80,000.

Bancroft, Ont.—There is a probability of a new industry being established here to make broom handles, spools, etc. G. A. Turner and Wm. Paul, of Toronto, are interested.

Refrigeration

Hamilton, Ont.—A scheme providing for the establishment of a cold storage system in connection with the central market meat ball is being seriously considered by some of the aldermen.

Marine

Bathurst, N.B.—It is announced that arrangements are being made for the completion of the harbor development work here.

Ottawa, Ont.—The Government steamer Montmagny, which was rammed and sunk by the collier Lingan in the St. Lawrence over a year ago, is to be raised. The steamer now lies in ten fathoms of water off Grosse Isle. The contract for raising her has been awarded to the Levis Wrecking Company at $27,000.

Canadian Coasting Laws.—The Lake Carriers' Association, of Cleveland, Ohio, has been officially notified that the Canadian coasting laws have been suspended and American ships will be permitted to trade between Canadian lake ports during the remainder of the season. During the navigation season of 1914 there were 105 vessels of Canadian registry employed in the grain carrying trade on the Great Lakes, their total tonnage being 350,000. Owing to the transfer of many of these ships to the ocean trade, there are available this season only 56 Canadian ships, with combined tonnage of 109,000.

Personal

W. F. Hume, late manager of the Dominion Architectural Ironworks, Montreal, has been appointed shop superintendent of the Quebec Engineering Co., Quebec.

A. B. Smith, manager of the G. T. R. telegraphs, has resigned on account of ill-health. H. Hulatt has been appointed his successor, with headquarters in Montreal.

Captain Henry I. Matthews, who died last week at Lakeport, Ont., was the founder of the Lakeport Canning Factory, which was one of the constituent plants of the Canadian Canners, Ltd. Until the latter organization was absorbed by the Dominion Canners, Captain Matthews was one of its directors.

Trade Gossip

The Kelsey Wheel Co., Windsor, Ont., have increased their capital stock to $250,000.

The Canadian Westinghouse Co., Hamilton, Ont., have been awarded a contract by the City of Ottawa, Ont., for switchboard and equipment, and also transformers, at a total cost of $23,165

The Monarch Engineering Co., has been licensed to carry on business in the Province of Ontario, with a capital not exceeding $40,000. Alex. Fraser, of Niagara Falls, Ont., is the attorney.

Large Munition Contract.—The officials of the Dominion Steel Corporation were in Ottawa last week working on an unusually large munition contract. No definite announcement has yet been made, but it is understood that arrangements are practically completed for the work to go ahead.

Spanish River Pulp & Paper Mills.—The annual meeting of shareholders was held on October 1, at which the report for the year ending June 30, 1915, was approved. The following were elected to the board of directors: W. E. Stavert, P. B. Wilson, T. Watson Sime, C. E. Read, B. J. Tooke, G. H. Mead and T. Gibson. The same board was elected by the Lake Superior Paper Co.

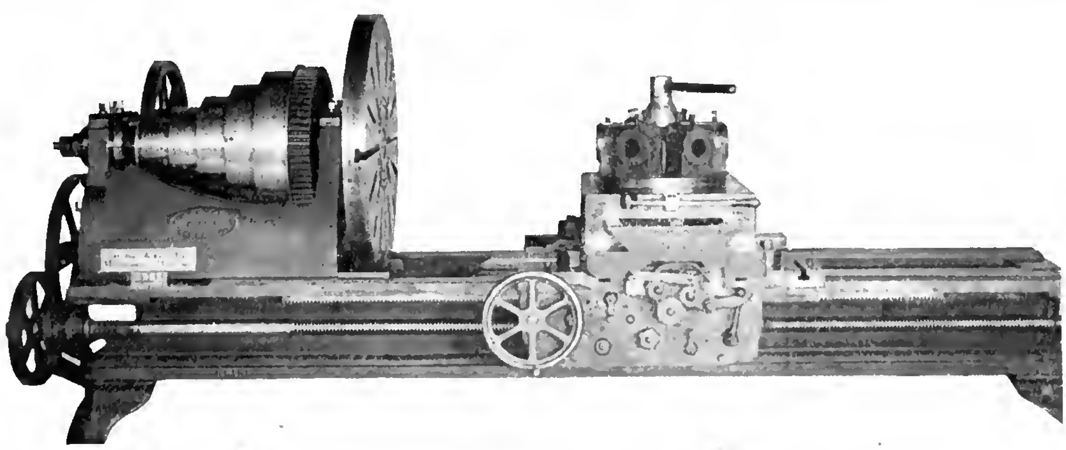
Canada Steamship Lines.—Five vessels of the Canada Steamships Lines fleet, now engaged in lake trade, are being reconstructed, and will be placed at the disposal of Canadian grain exporters for ocean service. This is the first step taken by the commission at Ottawa, of which Hon. Robert Rogers is president, to relieve the scarcity of tonnage, which is hampering Canadian export trade.

Dominion Steel Foundry Co.—An addition, 100 x 160 feet, to the main foundry building of the Dominion Steel Foundry Co., Hamilton, Ont., is nearing completion. The company has installed in this addition one 25-ton acid open-hearth furnace and one 30-ton Shaw electric 4-motor crane. The company has also installed a complete outfit for machining 3-inch British shrapnel shells and machinery for finishing 4.5 howitzer shells.

The Eastern Car Co., New Glasgow, N.S., subsidiary of Nova Scotia Steel & Coal, has shipped the first consignment of the two-thousand-car order placed by the Russian government. The shipment, consisting of 250 complete cars, was made in one of the vessels controlled by the parent company, and will travel to its destination via the Panama Canal. It is estimated that orders from the Russian and French governments will require fifteen steamers to transport. The company has increased its output during the past few weeks from 20 to 40 complete cars.

Ambulances Gift.—Noel Marshall accepted a motor ambulance on behalf of the Red Cross Society on September 30 from the employees of the McLaughlin Carriage Co., at the warerooms of the company in Toronto. Mrs. Ward, president of the Toronto District W.C.T.U., also presented a motor ambulance to the Red Cross Society through Mr. Marshall later in the afternoon at Willard Hall, Gerrard Street. Both these machines were the product of the McLaughlin Carriage Co., and will be sent to the front.

Inquiry for Grain Elevator Equipment.—A number of elevators for storage of grain are likely to be constructed in the near future by a foreign government these varying in capacity from 250,000 to 1,250,000 bushels. Such work has been supplied in the past from Germany but as further supplies are not obtainable from that country the government in question desires to be informed from Canadian sources the cost of elevators both in construction and in re-



If what you want is not advertised in this issue consult the Buyers' Directory at the back.

gard to machinery and equipment. Information can be obtained by reference to the Department of Trade and Commerce, Ottawa (File A-1575).

The Turbine Equipment Co., Toronto, have recently secured the following contracts:—Canadian Copper Co., Copper Cliff, Ont., two 7½ million-gallon a day De Laval centrifugal pumps, direct connected to Canadian Westinghouse motors; Pilkington Bros., Thorold, Ont., one De Laval 3-stage pump, direct connected to Canadian Crocker Wheeler motor; Samuel Austin & Co., Thorold, Ont., one De Laval single-stage pump, direct connected to Canadian Crocker Wheeler motor; Kerr Lake Mining Co., Cobalt, Ont., one De Laval 3-stage pump, direct connected to Canadian Westinghouse Co. motor.

Soo Canal Traffic—Eastbound traffic through the St. Mary's Falls Canals, Sault Ste. Marie, Ont., shows a large increase over September of last year, according to the monthly statistical report compiled by the engineer's office. Last year, 6,368,408 tons were locked through eastbound, while during September, 1915, 907,771 tons passed the Soo. The increase is shown in the entire list of commodities except flour, iron ore leading, of which 7,796,965 tons were carried through, or 2,509,808 tons more than September, 1914. Copper also shows a heavy increase, being 9,160 tons over last year. The amount of grain and wheat locked for lower lakes elevators was 31,927,870 bushels, against 27,579,621 for September, 1914, or an increase of 4,668,249. The passenger list eastbound during September this year was nil. Westbound traffic shows a decrease. The total freight, however, showed a net increase of 2,561,735 tons, 445 more passages being registered for the month over last year.

Catalogues

Trucks.—The "Lifton" truck for handling goods piled on platforms is described in a bulletin issued by the W. S. Mahaffy Co., Toronto. The truck is illustrated, and the essential particulars are given.

Reducing Valves, made by the James Morrison Brass Mfg. Co., Toronto. The J.M.T. standard reducing valve is fully described in this bulletin, which also includes directions for installing, cleaning and method of operation. The bulletin is illustrated.

"Foundry Filosofy" is the title of a booklet published by the Hill & Griffith Co., Cincinnati, Ohio, manufacturers of foundry facings, supplies and equipment. The booklet is a combination of

Advertising

"Advertising is the education of the public as to who you are, where you are, and what you have to offer in the way of skill, talent or commodity. The only man who should not advertise is the man who has nothing to offer the world in the way of commodity or service."—*Elbert Hubbard.*

"Filosofy" for foundrymen and a brief description of the company's products. Polishing and plating supplies are included among the latter.

Steam Traps.—The Canadian Johns-Manville Co., Toronto, Ont., have issued a bulletin describing the "Johns-Manville" steam trap. The principal features of this trap are dealt with in detail, and the illustrations show the general construction. A table gives the capacity and dimensions of each size, and a list of users is also included.

Edison Mazda "C" Lamps, for standard lighting service, is the title of Bulletin No. 43603A, issued by the Canadian General Electric Co., Toronto. A full description is given of the Edison Mazda lamp and the wide field of application is dealt with. In the latter connection are a number of views showing a variety of installations in addition to illustrations of lamps, reflectors, and fixtures. Tables are included giving date on these lamps.

Steam Specialties and Mill Supplies.—Lytle, Smith & Co., Montreal, Que., have issued a new catalogue "A" dealing with an interesting line of flexible metallic hose, steam traps, packings, miscellaneous steam goods, tools, mill supplies, etc. The various products are illustrated and described, while complete price lists are included. This is a well gotten up catalogue, containing 62 pages, with index, and will be found useful for engineers and steam users to have on hand for reference.

TORONTO HYDRO-ELECTRIC REPORT

NET earnings of $303,686 for the first half of this year were recently reported by the Toronto Hydro-Electric system. The money was spent as follows: Interest, $130,948; interest on past instalments, $4,993; sinking fund instalments, accrued, $46,635; balance for depreciation and annual adjustments, $121,100.

The income of the concern for the first six months totalled $770,553, made up as follows: Commercial lighting, $295,708; commercial light, $174,662.51; municipal building light, $9,878; municipal power earnings, $80,287.84; municipal street lighting earnings, $170,916.20; rent of meters, $805.24; stores charges, $21,122.57; system consumption, $3,279.02; miscellaneous general expenses, contract account, $2,815.17; other municipalities, $1,700.39; non-operating income, $9,378.53. The cost of electric current was $184,835.63, and the expenses of operation, etc., $228,031.60.

The assets of the system are placed at $7,596,947.78, and the liabilities amount to $121,109 less.

General Manager Couzens declares that in spite of the war business has increased, that the unit cost of operation has decreased over 10 per cent., that the Hydro in the period mentioned benefited to the extent of $94,000, that the amount of power purchased from the Provincial Commission was $185,000, as compared with $147,000 in the same period last year, and that the system has not yet received from the city the proceeds of the debentures sold some months ago, and the amount due in respect of the loss on the bonds last year, amounting altogether to $1,350,000. The city, however, has a contra account for about a million dollars for interest and sinking fund.

AUSTRALIAN TRADE AND THE WAR

A COMPARISON of the manner in which Australian and Canadian trade have been affected by the war, and an official statement as to the number of soldiers Britain's Antipodean colony has contributed to the allied cause is contained in a report to the Canadian Government by Trade Commissioner Ross in Melbourne.

Australian trade during 1913-14 totalled $812,812,658, as compared with a Canadian total of $1,113,562,107. In 1914 her trade was but $608,652,014, as compared with Canada's showing of $1,078,173,240.

Since the declaration of war on August 4, 1914, the Commonwealth had organized, equipped and despatched 76,566 troops for active service abroad. At the present time 40,400 troops are in camps in Australia for despatch to the front. The Government has announced its determination to continue to train, equip and transport to the seat of war every available man presenting himself for service and who succeeds in passing the necessary medical examination.

To date, the grand total of the Australian expeditionary forces raised has reached 117,000 men, excluding 8,000 troops of the citizen forces mobilized for home defence. Reinforcements are going forward at the rate of 5,300 a month, and this number will be increased to 10,600 in October and in November. The various divisions comprise infantry, light horse, ammunition columns, artillery, engineers, army service corps, army medical corps, flying corps, veterinary sections, bridging train and pay corps.

At the request of the Government of India a section of the Australian flying corps was despatched to the Persian Gulf, and is working in conjunction with the Royal Flying Corps. Further reinforcements are to be sent.

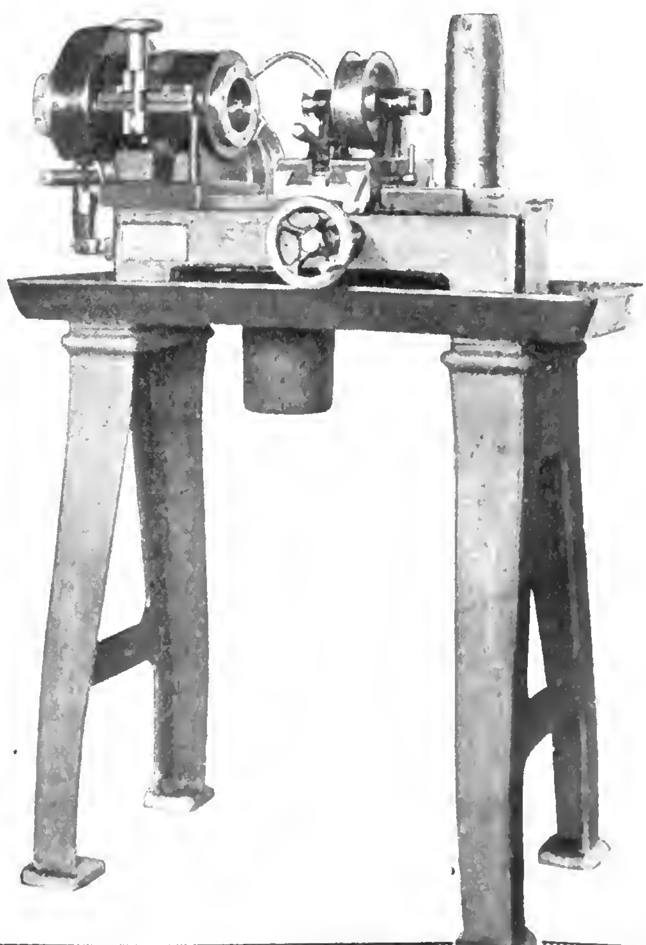
Thread Milling Machines

For High Explosive Shells

Designed for the purpose of milling the thread in the base and nose of high explosive shells.



Shell is placed inside a revolving spindle and is self-centering. A perfect thread is produced in base of shell in approximately 2½ minutes.

Milling Cutter is made from best high-speed steel, by Brown & Sharpe, from special design by Holden-Morgan Co., and is so shaped that it can be sharpened without changing the form. Cutter is designed to mill the top of thread as well as the depth.

Machines are fully equipped for work, including oil pump. Fitted with automatic stop motion, which stops machine when thread is completed. One operator can run several machines. Eliminates all risk of having shells rejected on account of thread being stripped, as is liable to be the case when tapped by the old method.

Write for complete particulars, prices, etc.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Quebec, Que.—Bronneau & Frere are receiving prices on steam pumps, steam boilers, etc.

Vancouver, B.C.—B. T. Rogers will build a machine shop to cost $25,000 on Granville street.

Guelph, Ont.—The Guelph Carriage Top Co. is in the market for a 50 h.p. to 80 h.p. engine.

Chatham, Ont.—The water commissioners have decided to buy a new boiler for the electric light plant.

St. Andre de Kamouraska, Que.—M. L. F. Germain will build a factory for the manufacture of scales, etc.

Petrolia, Ont.—Wm. Pratt has in hand the disposal of a machine and blacksmith shop fully equipped.

Toronto, Ont.—A compressed air tank exploded at the plant of the Canadian Ornamental Iron Co., River street, on October 5.

Chippawa, Ont.—The Norton Co. will make an addition to their plant at this place. The company manufacture abrasive wheels.

Cobalt, Ont.—New machinery is being installed in the McIntyre mill at Porcupine which will increase the capacity to 450 tons per day.

Vancouver, B.C.—R. V. Winch & Co. are in the market for one steam-driven air compressor of from 325 to 400 cu. ft. of air per minute with receiver, etc.

Rock Island, Que.—The Union Twist Drill Co. has let contract to Loomes & Dakin, Sherbrooke, for the erection of an addition to its plant at this place.

Bathurst, N.B.—It is announced that a brass and iron foundry will be established here. Messrs. Frank and Percy McCallum, formerly of Chatham, are at the head of it.

Galt, Ont.—Architect Evans has almost completed the plans for the new factory to be erected for the Galt Machine Screw Works. It is expected that construction will begin shortly.

Mount Brydges, Ont.—The Canadian Crow Motor Co. are building a factory here for making motor cars. The building will be 200 ft. by 50 ft. and will cost about $12,000. W. H. Longfield of this place is the contractor.

Smith's Falls, Ont.—The Rideau Power Co., contemplate completing the hydro electric power development here by installing two additional units. M. G. Henniger is the managing director.

Port Stanley, Ont.—It is understood that the Port Stanley Railway Commission will proceed at once with the erection of their railway shops and car barns. The contract has been let to Hayman & Sons at $27,000.

Bedford, Que.—Gray & Dunn, Montreal, have received the contract for the erection of a factory to cost $9,000 for the Bedford Mfg. Co., Bedford, Que. Saw and lathe equipment will be purchased by F. D. Welsh, manager.

Windsor, Ont.—The Water Commissioners are preparing specifications for a new 200-h.p. boiler they are contemplating installing in the waterworks plant in the near future. As soon as the specifications are completed tenders will be called for.

St. Thomas, Ont.—The incorporation at Ottawa recently of the Dominion Brake Shoe & Foundry Co. of St. Thomas with a capital stock of $200,000 is announced. It is believed the men interested are connected with the American Brake Shoe & Foundry Co. of the United States and Montreal, and that a large foundry will be erected shortly.

General Industrial

Prescott, Ont.—The Newell Mfg. Co. will probably establish a plant here.

Montreal, Que—The National Paper Co. will build a plant to cost over $100,000 for the manufacture of coated paper.

Hamilton, Ont.—The National Paper Goods Co. will build an addition to their factory.

Acton, Ont.—The Wallaceburg Knitting Co. plant may be moved here. The town will be asked for a loan of $10,000.

Mitchell, Ont.—The Walter Thompson & Son Co. have bought from the Canadian Cereal Co. the oatmeal mill in Seaforth, and are having it renovated.

Georgetown, Ont.—The by-law to grant assistance to the Glass Garden Builders has been passed. The company will erect a factory for making greenhouses.

Toronto, Ont.—A representative of the Kellogg Co., of Buffalo, N.Y., manufacturers of oil cake, and similar products, has been here securing information with regard to a proposed Canadian factory.

Toronto, Ont.—R. G. Long & Co., of 439 Wellington Street West, have purchased a site on King Street, west of Bathurst, for approximately $21,000. It is the intention of the purchasers to erect a five-storey building, at a cost of $80,000, for the manufacture of gloves, sweaters, and a general line of workmen's apparel.

Chatham, Ont.—The G.T.R. has agreed to install and maintain the interlocking switch necessary to put a spur into the proposed site of the sugar factory which will be erected here. This has been holding up the proposition of the Dominion Sugar Co. who are considering the erection of a million-dollar plant in this city. The city council will now prepare the by-law granting a free site to the sugar company, and a by-law will be submitted to the electors.

Municipal

Petrolia, Ont.—The town council at a special meeting by a vote of five to four, decided to take over the electric light plant at $11,280.

Dryden, Ont.—The installation of a telephone system is contemplated. A by-law will be voted on to authorize the expenditure of $5,000.

Newmarket, Ont.—A by-law is contemplated to guarantee the bonds to the extent of $15,000 of a boot and shoe concern as an inducement to locate here.

Renfrew, Ont.—The town council are negotiating with a company who propose establishing a plant here or in this district. M. J. O'Brien is interested in the enterprise.

Petrolia, Ont.—A by-law will be submitted to the ratepayers in connection with the proposed beet sugar refinery. E. Hyatt and R. G. McKenzie are interested in the proposition.

Sherbrooke, Que.—Tenders are all in for the proposed gas plant. The city council will probably engage an expert to examine and report on the tenders before awarding the contract. Three bids were received, ranging from $30,980 to $40,042.

When times are good, time is cheap.
When times are hard, time is dear.

When your factory was running overtime, and you had to stop your advertising because you couldn't fill your orders, you didn't feel so badly if an occasional employee wasted an occasional hour.

It was bad business then, or any time, but, well "times were good."

Now, in these days when efficiency and economy are the watchwords that must lead us in to the promised land of peace and plenty again—what about the time of your employees that you are paying for, every minute of it? Are you getting it—every minute of it? Have you a time-recording system that will do these things:

1. Show every employee in figures of his own making how much of your time he has wasted.
2. Save the big waste in "walking time" from the place of "punching in on the clock" to the bench or desk.
3. Enforce publicity, and a lot of it, at every registration.
4. Leave the employee satisfied with the registration, because it is plainly visible and is known to be unalterable.
5. Give you a practically ready-made pay-roll at the end of the week.

If you haven't, then the golden minutes are draining away unseen, every day and four times a day, and with them your profits, maybe the small margin that makes all the difference between dividends and no dividends, Mr. Manufacturer.

If you would like to become posted on the workings of a System that is designed to stop the Time-leaks in YOUR factory, write us to-day.

The International Time Recording Company of Canada, Limited
TORONTO, CANADA

F. E. MUTTON,
General Manager

Phone Main 2469

Offices—RYRIE BLDG.
Cor. Shuter and Yonge Sts.

Toronto, Ont.—Mimico and New Toronto may get a sewerage system, a disposal plant, and a water pumping system sufficient for the needs of the two municipalities for $125,000. Nineteen tenders were opened on Oct. 5, at a joint meeting of the two councils, and while no tender was accepted, the price of the work will be approximately as stated.

Electrical

Winnipeg, Man.—The city will purchase a number of ornamental arc lamps.

Hensall, Ont.—The town council are considering the installation of a hydro-electric power and lighting system.

Galt, Ont.—The installation of an ornamental lighting system is contemplated by the town council at an estimated cost of $6,860.

Brantford, Ont.—At a meeting of Brantford Township Council held recently, a by-law was passed authorizing the township to enter into an agreement with the Hydro-Electric Power Commission, and the reeve of the township was given power to sign the contract.

Contracts Awarded

The Canada Iron Corporation have been awarded the contract for 2,400 lineal feet of cast iron water pipe by the City of Winnipeg.

Hull, Que.—The City Council have let the contract for the installation of a street lighting system to Marchant & Donnelly, Ottawa, at $4,900.

Ottawa, Ont.—The City Council have awarded the contract for a switchboard and apparatus to the Canadian Westinghouse Co., Hamilton, Ont., for $11,-912.

Hull, Que.—A contract has been awarded by the City Council to E. Laurie Co., Montreal, for two 8-million-gallon De Laval centrifugal pumps, with Canadian Westinghouse motors.

Ottawa, Ont.—The City Council have let the following contracts:—Supply of lock bar pipe, Laurin & Leitch, Montreal, $194,400; pumps, Escher-Wyss Co., Montreal, $10,900; motors, Canadian Westinghouse Co., $14,600; special castings, Victoria Foundry Co., $2,455; valves, General Supply Co., $14,518.

Lambeth, Ont.—The Town Council have awarded the contract for hydrants and valve boxes to the London Foundry Co., and for cast iron pipe to the Gartshore-Thompson Foundry Co., of Hamilton. The Des Moines Bridge and Iron Co. will supply a water tank. The above work is in connection with a new waterworks system.

Railways—Bridges

Ottawa, Ont.—The Ottawa and New York Railway Co. has given notice of an application to the Railway Commission for approval of a lease from the Ottawa and New York to the New York Central Railway Co.

Toronto, Ont.—Plans for hydro radial trunk lines from Sarnia to Toronto, touching London, St. Mary's Stratford, Guelph and points east, will be submitted to a representative meeting of the Hydro radial to be held in Guelph during the present week.

Tenders

Toronto, Ont.—Tenders addressed to the secretary-treasurer of the Board of Education will be received until Friday, October 15, 1915, for new school building on Sydenham street. Specifications may be seen and all information obtained at the office of the Superintendent of Buildings, City Hall, Toronto.

Ottawa, Ont.—Tenders will be received up to Tuesday, October the 19, for the undermentioned items for delivery to H.M.C. Dockyards at Halifax, N.S., and Esquimalt, B.C.: Brass bars, antimony, iron firebar, brass sheets, aluminum, pig iron, brass tubes, steel angles, iron angles, copper sheet, steel boltstaves, iron boltstaves, copper tubes, steel plates, iron sheets, zinc plates, steel sheets, India rubber, lead, milled steel for tools, sheet packing, or sheet, etc. Forms of tender and all information may be obtained by application to the undersigned, or to the Naval Store Officer at H.M.C. Dockyard, Halifax, N.S., or Esquimalt, B.C. Applicants for forms are requested to state definitely the item or items on which they desire to tender. G. J. Desbarats, Deputy Minister of the Naval Service.

Building Notes

Toronto, Ont.—An addition will be built to the plant of the Swift Canadian Co., West Toronto.

Toronto, Ont.—A permit has been issued for the erection of a three-story brick school on Bartlett Avenue, near Hallam Street, to cost $52,900.

Fredericton, N.B.—R. Chestnut & Sons have applied to the city council for authority to erect a building to be used as a magazine for the storage of explosives.

Hamilton, Ont.—It is estimated that the new bridge at Valley Inn Hill will cost $500,000 to construct. Rock for foundations has been found at 91 feet, and the advisability of proceeding with the work is being considered.

Brighton, Ont.—The local Board of Education has awarded the contract for a new school to the Sutherland Construction Co., of Toronto. The tender amounted to $45,980. Telephone and heat regulating systems to cost $1,063 may be installed at a later date.

Toronto, Ont.—Plans for the new Union Station were submitted to the city architect on Oct. 6, by the Toronto Terminal Co., with a request for a permit to go on with the work. The expenditure provided for $3,340,000, although the original estimate was only $3,000,000. The Dominion Railway Board has approved of the plans, which provide for a station larger than that called for by present conditions.

New Incorporations

The Roelofson Machine & Tool Co. has been incorporated at Ottawa with a capital of $50,000 to carry on a machinery business at Toronto, Ont. Incorporators: Harry Riley, James White Bicknell and Alfred Bicknell, all of Toronto.

The Canadian McCall Incinerator Co. has been incorporated at Ottawa with a capital of $300,000 to take over patents for incinerators and carry on a manufacturing business at Toronto, Ont. Incorporators: Frank Denton, John Irwin Grover and James McEwen, all of Toronto.

Universal Appliance Mfg. Co. has been incorporated at Ottawa with a capital of $150,000 to manufacture automobiles, cycles, trucks, etc., at Toronto. Incorporators: John F. McGregor, Thomas S. Giles and John S. Duggan, all of Toronto, Ont.

The Canadian Tygard Engine, Ltd., has been incorporated at Ottawa with a capital of $3,000,000 to manufacture the "Tygard" rotary steam engine and gas engines. Head office at Toronto. Incorporators: Charles H. C. Leggott and William W. Perry, both of Toronto, Ont.

Refrigeration

Ottawa, Ont.—The Ottawa Dairy Co. have let the general contract for the erection of an ice-making plant to the Wegnier Machine Co., Buffalo, N.Y. The cost of plant and building is estimated at $15,000.

Wood-Working

Trenton, Ont.—J. Whiteley is in the market for woodworking machinery, etc.

Montreal, Que.—Fire did about $4,000 damage to the M. Charion Co. saw mill on Burnet street, on Sept. 30.

Preston, Ont.—The Preston Car & Coach Co., is preparing to instal machinery for the manufacture of shell boxes on a large scale as the Government has placed a big order with them.

Cache Bay, Ont.—George Gordon & Co. are in the market for two double cutting band mills, one horizontal resaw, together with edgers, lath mills, trimmers, etc., to be installed in a mill to be built at Cache Bay at a cost of $75,000.

Personal

E. S. Edmondson has tendered his resignation as managing director of the Interurban Electric Co.

Charles Stewart, one of the senior partners of Burrow, Stewart & Milne, founders, died at his home in Hamilton, Ont., on Oct. 8, at the age of 78.

J. D. Shields, chief inspector of electrical appliances for the City of Toronto, has resigned, the office having been abolished by the Provincial Hydro Commission.

William Walters, inspector of the new harbor improvements at Toronto, Ont., died at Lindsay, Ont., on Oct. 5. The deceased was born at Kingston, Ont., on Aug. 11, 1854.

Lieut.Col. Frederic Nicholls has been appointed acting president of the Dominion Steel Corporation on account of the continued indisposition of the president, T. H. Plummer.

Capt. Charles H. Jenkin, for many years in command of Grand Trunk car ferry boats, and well known in Great Lakes marine circles, died at his home in Detroit last week after a long illness.

William H. Boughner, assistant engineer of St. Thomas, Ont., has been appointed civil engineer at Port Arthur, Ont., with a salary of $2,500 per year. Engineer Boughner is a native of St. Thomas, and a graduate of Queen's University.

Major T. A. Russell, vice-president and general manager of the Toronto, Ont., Russell Motor Car Co., while in Detroit recently placed orders for motors and parts for armored motor trucks, for which he received an order while at the military camp at Salisbury Plain, England.

C. H. Fullerton, mining engineer of New Liskeard, Ont., has been appointed superintendent of Colonization Roads for the Province of Ontario, taking the post made vacant by the death in France at the battle of St. Julien of Major G. W. Bennett.

C. E. Henderson, assistant city engineer of Port Arthur, Ont., has been appointed city engineer of St. Augustine, Florida. Mr. Henderson graduated in civil engineering at the University of Illinois in 1906. He has been assistant city engineer of Port Arthur since June, 1910.

Corporal J. J. Campbell, formerly Montreal representative of the Swedish General Electric Co., and latterly of the 13th Battalion, Royal Highlanders of Canada, is reported as being a prisoner of war at Wetzlar, near Giessen. Later when announcement was made of decorations by the Czar of Russia, Mr. Campbell received the Cross of St. George, first class.

Trade Gossip

The Canadian Furnace Co. report good business. They are shipping about 700 tons of pig iron every day.

The Preston Car & Coach Co., Preston, Ont., has received an order for a number of steel frame electric cars from the Lake Erie & Northern Railway.

The Canadian Tygard Engine Co. has opened an office at 202 Royal Bank Building, Toronto, Ont., to demonstrate the "Tygard" rotary steam engine.

Regina, Sask.—The Publicity Commissioner has issued a brochure containing views of the principal public buildings, residences, street scenes, etc., in the City of Regina.

The Canadian Hoskins, of Walkerville, Ont., makers of electric, gas and oil furnaces, and pyrometers have opened up a sales office at 112 St. James St., Montreal, Que. The office is in charge of T. E. Freeman, B.A. Sc.

Orangeville, Ont.—The Ontario Hydro Electric Power Commission has taken over the Pine River Light & Power Co. dam and power plant at Horning's Mills. The Town of Orangeville will take over and operate the company's distribution system.

Canada Machinery Co.—The Canada Machinery Corporation of Galt, Ont., is understood to be operating at full capacity. The plants have been busy for some time past on the manufacture of machinery for industrial concerns that are engaged in the production of war munitions.

If what you want is not advertised in this issue consult the Buyers' Directory at the back.

Advertising

"Advertising is the education of the public as to who you are, where you are, and what you have to offer in the way of skill, talent or commodity. The only man who should not advertise is the man who has nothing to offer the world in the way of commodity or service."—*Elbert Hubbard.*

B. C. Wants War Orders.—With the object of improving British Columbia's position in the distribution of war contracts, a deputation from that Province visited Ottawa and interviewed the Prime Minister, Hon. Martin Burrell and Hon. A. E. Kemp on October 8. The deputation included Blair, Cunningham and Bushby, of Vancouver, and Wesley Newcombe, of Victoria.

Victoria, B.C.—The Canada Potash and Algin Co., has its arrangements nearly completed for beginning work. This company was promoted by Macdonald Fahey, who is its managing director, the other directors being Charles R. Dinsford, Captain D. McIntosh, Arthur H. Pigott and T. B. Mohler. The company controls in Canada the Mohler processes for the treatment of kelp made from seaweed. A plant has been leased at Sidney in which machinery is being installed for making kelp, potash and gum algin.

Toronto, Ont.—Sir Adam Beck, Hon. I. B. Lucas and W. K. McNaught of the Provincial Hydro Commission, together with Mr. Gaby, engineer, had a conference on October 5, with Premier Hearst and other members of the Ontario Cabinet with reference to power development at Niagara Falls. The proposed additional development is in the neighborhood of 100,000 horse-power, and the consultation, it is understood, had to do with financial and kindred matters associated with the enterprise. Premier Hearst, spoken to after the meeting, declared there had been merely a consultation, and there was no definite announcement to make.

English Firms Want Agents Here. — Many well-known manufacturing firms in the United Kingdom seek agents to represent them in Canada. To. C. Hamilton Wickes, British Trade Commissioner to Canada and Newfoundland, have come numerous requests for help in this matter. Mr. Wickes, who has been in the United Kingdom since last February to familiarize himself with trade conditions there since the war, has returned to Montreal. Members of Canadian manufacturing firms, desirous of obtaining new commercial connections with firms in the United Kingdom may obtain information as to appointments with Mr. Wickes by seeing T. B. Wainwright, chief clerk in the offices of the British Trade Commissioner, 3 Beaver Hall square.

Catalogues

Safety Valves for high and low pressure, and superheat, are illustrated and described in a bulletin issued by the James Morrison Brass Mfg. Co., Toronto, Ont. A price list is included for the different types.

Quality Fluxes is the title of a bulletin issued by the Reade Mfg. Co., Hoboken, N.J. The bulletin fully describes three of the company's principal products, the "Incomparable" soldering fluid, tinning solution and "Readina" soldering solution. The advantages to be gained by using these materials are dealt with in detail and a price list is included for various quantities.

Dart Unions.—The Dart Union Co., Toronto, Ont., have issued a 16-page booklet for the purpose of again bringing to the attention of the trade the "Dart" union pipe couplings and to point out some of the advantages to be had from their use. The principal features covering the construction of "Dart" unions are dealt with a complete line of fittings are illustrated and listed.

The Yawman & Erbe Mfg. Co., Rochester, N.Y., have issued an interesting booklet entitled the "Proper Place for Blue Prints and Drawings." The booklet deals with filing systems for blue prints and drawings, and illustrates a few cabinets for filing such matter, emphasizing the necessity of having drawings filed in such a manner that they can be found when required and also be preserved in good condition.

Shells and Shell Furnaces is the title of circular No. 140 just off the press and being distributed by Tate-Jones & Co., Inc., Pittsburg, Pa. The circular gives details of heating equipment for the forging, annealing, nosing, heat treating, banding, baking of shells, and annealing of cartridge cases for shells as called for by the specifications of various European Governments. The various types of furnace are illustrated and described in detail, and principal dimensions are included for the regular sizes.

Refractory Efficiency Engineering is the title of a 42-page booklet compiled by the Elk Fire Brick Co., of Canada, Hamilton, Ont. The booklet is divided into two parts. The first deals with the preparation and blending of clays, the manufacture of fire brick by various processes and other similar matter. Part two deals more particularly with the company's products and includes references to their equipment, brands, the engineering department and policy. A number of cuts are included showing standard and also some of the ordinary special shapes of fire brick. The concluding pages contain some useful mechanical tables.

Book Reviews

Commission of Conservation Sixth Annual Report.—Even casual reference to the annual reports of the Commission of Conservation indicates the wide range of interests with which the Commission is concerned. In this respect, the Commission's sixth annual report, which has just been issued, is no exception. Well-informed discussions are given concerning Canada's resources in forests, fields, mines and streams, and important papers are included on technical education, agricultural instruction, providing sanctuaries for birds and last, but by no means least, an important place is given to housing and town planning. Although the war has hampered some aspects of the work of the Commission, steady progress has been made in the matter of town planning. In the conservation of forests steady progress has also been made. Inventories of Canadian forests are being compiled by the Commission for the first time, and much has been done during the past year to lessen the number of forest fires along railway lines. The agricultural surveys and illustration farms operated for some years by the Commission have proved of such value that the Federal Department of Agriculture has recently taken over the work and is largely extending it. Canada's mineral resources are considered at length by Dr. Frank D. Adams, by Dr. Eugene Haanel and by Mr. W. J. Dick. In connection with water-powers, especially as applying to boundary waters, interesting and valuable papers by Messrs. A. V. White and Leo. G. Denis, are included in the report. The report is splendidly illustrated, and a carefully prepared index makes it of unusual value

Test Methods for Steam Plants, by Edward H. Tenney., 224 pages, 7¼ x 5 in., 85 illustrations. Published by the D. Van Nostrand Co., New York City. Price $2.50 net. This is a new book dealing with a phase of power plant operation which is not usually given the consideration that its importance demands. Economical operation of steam power plants can only be secured by the adoption of test methods to ascertain where losses are creeping in so that they can be eliminated as far as possible. This book has been written with the object of bringing into one volume those methods of analysis which can be used to good advantage in the power plant, and will aid the power station engineer in keeping his costs at the lowest figure. As the economical generation of steam depends largely on a suitable quality and supply of fuel and also on the correct design of the furnace, a considerable portion of the book is devoted to this phase of the subject. The remaining part deals more particularly with test-

ing of prime movers and lubricants. There are six chapters and an appendix. The first chapter on the purchase and testing of coal, deals, among other subjects, with the calorific value of coals and various methods of determination. The second chapter is devoted to the question of economical combustion. The treating and testing of water for boiler feed purposes is covered in chapter three which also describes several methods and appliances for treating water. Chapter four deals with evaporation tests in boilers and describes several methods and apparatus for testing flue gases. The fifth chapter, entitled "Methods of testing prime movers," is very comprehensive and describes methods of conducting tests and the apparatus used. The testing of power plant lubricants is described in the sixth chapter. Throughout the book are introduced a number of very useful tables, the last series Nos. 20 to 39 being included in the appendix. In addition to the main index there is an index of contents and lists of tables and illustrations. This book contains a lot of useful information for the power plant engineer of a kind that is not readily obtainable in the ordinary course of his duties.

CLASSIFIED ADVERTISEMENTS

¶ Those who wish to sell or buy a business, obtain competent help, connect with satisfactory positions, or secure aid in starting new enterprises should not fail to use the Want Ad. Page of "CANADIAN MACHINERY."

¶ If you want to sell or buy a second-hand lathe, planer or any other shop equipment, let "CANADIAN MACHINERY" pick out a seller or buyer for you. How about that second-hand engine or boiler which you would like to dispose of?

Rates (payable in advance):—2c per word first insertion, 1c per word subsequent insertion. 5c additional each insertion when Box Number is required. Each figure counts as one word.

FOR SALE

FOR SALE — FOUNDRY AND MACHINE shop, with lathes, shapers, drills, etc. Shop 90′ x 30′. Ten years old. Paris, Ont. Apply John Stewart, 203 William Street, Brantford, Ont.

FOR SALE—25 HORSE STEAM POWER, complete, consisting of portable firebox boiler and stationary engine in good running order. Will be sold at a bargain. Thos. F. Mullin, Chepstow P.O., Ont. (18)

WANTED

AGENTS—ENGINEER DESIRES TO REPRESENT manufacturing firms in Montreal and district on a commission basis. Apply G. S. B., care of Canadian Machinery, Montreal. (17)

WANTED—POSITION AS SUPERINTENDENT. Am open to consider the position of superintendent of any firm manufacturing war munitions. Have special knowledge of materials and have designed machinery and solved problems in connection with machining and forging shells. Have thorough understanding of operations. Am not looking for fancy salary. William Rodgers, A.M. Can. Soc. C.E., 1386 Delorimier Ave., Montreal.

Montreal, Que.—J. R. Walker & Co. paper manufacturing plant at Sault Au Recollet was destroyed by fire on Oct. 14, the loss being estimated at $25,000.

Tenders

Toronto, Ont.—Tenders will be received, addressed to the Chairman, Board of Control, City Hall, up to Tuesday, Nov. 9, 1915, for the supply of a radial drill for machine shop, Danforth avenue car barns. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

Winnipeg, Man.—Tenders, addressed to the Chairman, Board of Control, will be received up to Wednesday, Oct. 27, 1915, for the following supplies for the Fire Department: 3,000 feet 2½-inch cotton, rubber-lined fire hose; 12 non-interfering fire alarm boxes. Specifications and forms of tender may be obtained at the office of the Chief of the Fire Department, Central Fire Station.

New Westminster, B.C.—Tenders will be received up till October 29, for an electric freight elevator for Public Building. Plans and specifications may be seen on application to the caretaker of the Public Building, New Westminster, B.C.; at the office of Wm. Henderson, Resident Architects, Victoria, B.C.; at the Post Office, Vancouver, B.C., and at the Department of Public Works, Ottawa.

Windsor, Ont.—Tenders, addressed to J. F. Smythe, chairman Water Commissioners, Windsor, Ont., will be received up to Saturday, October 23, for the building and installing at the Windsor water works pumping station of one 200 h.p. steel Scotch boiler—to carry 160 lbs. pressure according to specifications and blue prints on file at the office of the Water Commissioners, City Hall, Windsor, Ont.

Port Arthur, Ont.—Tenders for fittings, customs examining warehouse, etc., Port Arthur, Ont., will be received until Friday, October 29, 1915. Plans, specifications and form of contract can be seen and forms of tender obtained on application to the Department of Public Works, Ottawa, at the offices of Thos. Hastings, Clerk of Works, Postal Station "F," Toronto, Ont., and Wm. Hood, Architect, Port Arthur, Ont.

Berlin, Ont.—Tenders will be received by the Chairman of the Sewerage Committee until Tuesday, October 26, 1915, for furnishing and installing sewage pumping machinery, comprising: (a) Two turbine pumps and all piping, capacity 500 gallons per minute, 33 feet head. (b) Two a.c. motors, switchboard and electrical instruments, installed complete. Specifications may be seen at the Engineer's Office, City Hall, Berlin, or at the office of Chipman & Power, consulting engineers, 204 Mail Building, Toronto.

Ottawa, Ont.—Tenders will be received up to Tuesday, November the 23rd, for the undermentioned items for delivery to H.M.C. Dockyards at Halifax, N.S., and Esquimalt, B.C.: Steel and iron bolts, nuts and rivets, electric cable and wire, mineral grease, castile soap, hard soap, turpentine, chemicals, cleansing powder, bunting. Forms of tender and all information may be obtained by application to the Naval Store Officer at H.M.C. Dockyards at Halifax, N.S., or Esquimalt, B.C., or to G. J. Desbarats, Deputy Minister of the Naval Service, Ottawa.

Contracts Awarded

London, Ont.—The Canadian Moloney Co., have been awarded a contract for transformers by the city council.

Trenton, Ont.—The contract for furnishing steel work and substructure of bridge over Trent river was awarded by Dominion Government to the Ontario Bridge Co., Toronto, at about $132,000.

Winnipeg, Man.—The Minister of Public Works has let the contract for the furnishing of the steel library and vault fittings for the new law courts to the Winnipeg Ceiling and Roofing Co., their price being $4,600.

New Incorporations

The Great West Direct Power Engine Co., Vancouver, B.C., has been incorporated with a capital stock of $25,000 to manufacture engines, machinery, etc.

The Paste & Gum Co. has been incorporated at Toronto with a capital of $40,000 to take over the business of the Paste & Gum Co. at Toronto, Ont. Incorporators: Robert Ellis and Goldwin Larratt Smith, all of Toronto.

The Ontario Cartridge Co. has been incorporated at Toronto with a capital of $40,000 to manufacture ammunition of all kinds at Ford, Ont. Incorporators: John Henry French, Walter Frank Tant and Forrest M. Keeton, all of Detroit, Mich.

The Belmont Oil & Gas Co. has been incorporated at Toronto with a capital of $40,000 to engage in the business of refining and treating artificial and natural gas, petroleum at Belmont, Ont. Incorporators: Frank Blair Tomb and John Stephenson Cousins, of London, Ont.

CLASSIFIED ADVERTISEMENTS

¶ If you want to sell or buy a second-hand lathe, planer or any other shop equipment, let "CANADIAN MACHINERY" pick out a seller or buyer for you. How about that second-hand engine or boiler which you would like to dispose of?

Rates (payable in advance):—2c per word first insertion, 1c per word subsequent insertion. 5c additional each insertion when Box Number is required. Each figure counts as one word.

FOR SALE

FOR SALE — FOUNDRY AND MACHINE shop, with lathes, shapers, drills, etc. Shop 90' x 30'. Ten years old. Paris, Ont. Apply John Stewart, 203 William Street, Brantford, Ont.

FOR SALE—25 HORSE STEAM POWER, complete, consisting of portable firebox boiler and stationary engine in good running order. Will be sold at a bargain. Thos. F. Mullin, Chepstow P.O., Ont. (18)

FOR SALE—CHEAP—ONE TWENTY-TWO-inch by ten feet bed Porter lathe, compound rest, steady rest, set change gears, large and small face plate, eighteen-inch four-jaw chuck, boring bar, four tool holders, and taper socket fitted. Box 156, Canadian Machinery.

BUSINESS FOR SALE—OWING TO ILL-health proprietor offers for sale his business, consisting of machine shop and blacksmith shop, with power hammer, tools, patterns and appliances used in the manufacture of artesian and oil well drilling tools and general work; will sell with or without buildings and land. Address Wm. Pratt, agent, Box 148, Petrolia, Ont.

WANTED

AGENTS—ENGINEER DESIRES TO REpresent manufacturing firms in Montreal and district on a commission basis. Apply G. S. B., care of Canadian Machinery, Montreal. (17)

WANTED—POSITION AS SUPERINTENDent. Am open to consider the position of superintendent of any firm manufacturing war munitions. Have special knowledge of materials and have designed machinery and solved problems in connection with machining and forging shells. Have thorough understanding of operations. Am not looking for fancy salary. William Rodgers, A.M. Can. Soc. C.E., 1386 Delorimier Ave., Montreal.

Personal

Lionel Hichens, chairman of Cammell, Laird & Co., has arrived in Ottawa to assume his duties as a member of the Shell Committee.

F. A. Skelton, director and secretary-treasurer of the Canadian Car & Foundry Co., Montreal, has left for New York on a business trip.

John Pugsley, at one time a member of the firm of Pugsley, Dingman & Co., soap manufacturers, Toronto, Ont., died in that city on Oct. 14, aged 63.

Hon. David MacKeen, of Halifax, N.S., at one time manager of the Dominion Iron & Steel Co., has been appointed Lieut.-Governor of Nova Scotia.

Charles Stewart, vice-president of Burrow, Stewart & Milne Co., iron founders, died at Hamilton, Ont., on Oct. 8. The deceased was born at Paterson, N.J., on Oct. 14, 1837.

W. W. Butler, vice-president of the Canadian Car & Foundry Co., Montreal, has left on an inspection trip, during which he will visit all the plants in the United States occupied on Canadian Car Co. orders.

Sir Hay Frederick Donaldson, K.C.B., recently appointed as technical adviser to the Shell Committee, has arrived in Ottawa. Sir Frederick Donaldson was until recently chief superintendent of Royal Ordnance Factories at Woolwich Arsenal.

George Cahoon, jr., has just been advanced from the vice-presidency of the Laurentide Co. to the presidency, to fill the vacancy caused by the death of Sir William Van Horne, and C. R. Hosmer assumes the vice-presidency. J. K. L. Ross was appointed to the vacancy on the board.

Charles Brewer Hunt, head of the milling firm of Hunt Bros., of the coal business bearing the same name, ex-president of the London Board of Trade, and one of the foremost business men of this city, died suddenly in London, Ont., on Oct. 11. The deceased was born at St. Thomas, 65 years ago. He was at one time actively associated with the London Electric Co., and was one of the pioneers of the milling industry in Western Ontario.

Walter Collis, manager of the Collis Leather Co., Aurora, Ont., died suddenly at the Western Hospital, Toronto, on Oct. 16. The late Mr. Collis was very well known in business circles. He was an expert in the manufacture of chrome leather, and for several years was engaged with the Davis Leather Co. of Newmarket. About three years ago, however, he severed his connection with the Newmarket concern and established the company of his name here. Deceased was 60 years of age.

Alexander Tropenas, inventor of the Tropenas converter, who died at Lyons, France, July 14, aged 55 years, served early in his career as a foreman in the plant of the French Bruges firm where he operated the Robert converter. Later he went to England to superintend the operation of the same converter for Edgar Allan & Co. at Sheffield. While there he invented his own converter, which he patented both in Great Britain and the United States. About 1901 he went to the United States to introduce his process for making small steel castings.

Trade Gossip

The Dominion Stamping Co., Walkerville, Ont., have recently installed a 5-ton electric traveling Northern crane manufactured by the Northern Crane Works, of Walkerville, Ont.

Ottawa, Ont.—The opening of a new transcontinental railway service was signalized by the departure on Oct. 12 of a Canadian Northern train of Pullman cars, bearing a party of senators and M. P.'s on an excursion trip to Vancouver, B.C.

Carriage Factories Ltd., who have plants at Montreal, Brockville and Orillia, have recently obtained large war orders for such articles as artillery harness, saddles, blankets, halters, ambulances, transportation carriages and water wagons.

Inverness Railway & Coal Co.—A receiver and manager of the Inverness Railway & Coal Co. has on the application of the National Trust Co., Toronto, trustees for the bondholders of the Inverness Railway & Coal Co., been appointed by the Court of Nova Scotia.

Rise in Custom Receipts.—An increase of over $2,000,000 in customs receipts is shown by the figures for September. Receipts totalled $8,029,665, as compared with $5,919,273 in September of last year, or an increase of $2,110,391. For the six months of the present fiscal year receipts have been $44,760,830, as compared with $43,044,913, an increase of $1,715,917.

Contracts Affected by Exchange.—The rate of exchange is reacting to the detriment of Canadian war contracts on this side. It is said that one contract for $50,000 fell through a few days ago solely on this account. It is felt that the Dominion Government should take steps to obviate the difficulty.

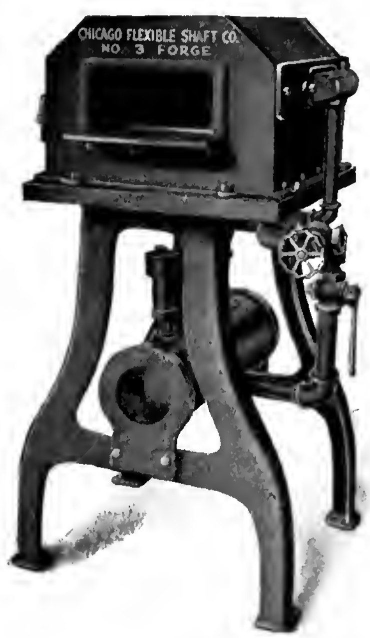
STEWART NO. 1 OVEN
Size of heating space, 5"x9"x13½".
Price with blower, $100.00.
Price without blower, $75.00.

Perfect Control Makes Tool Hardening Sure

A Stewart Forge or Furnace is always under the absolute control of the operator. He can get any heat quickly and hold it accurately without any wavering above or below. There is no guessing, no trusting to luck, no uncertainty about the result. He can heat every piece or lot exactly according to the grade of steel and to the purpose for which it is intended. As a result steel heating becomes an *exact* science when you use Stewart Furnaces; and spoilt work is reduced to a minimum.

Stewart Oven Furnaces, except those built for assaying and enameling, are made without muffles; have no need of them.

The Stewart line includes over 100 stock styles and sizes and the patterns of many special designs for various purposes. In this wide range there is one style and size which will exactly meet your needs. Let our service department help you find it. We will ship it on 30 days' approval. Write for catalogue 56.



No. 3 FORGE
Front opening, 3½"x8".
Rear opening, 3¾" diam.
(Rear opening same as front, if specified.)
Depth of heating space, 10".
Price with blower, $65.00.
Price without blower, $10.00.

Chicago Flexible Shaft Co.

210 to 230 Ontario St., Chicago, Ill.

The W. T. Rawleigh Co., who have a large factory at Freeport, Ill., and plants also at Memphis, Tenn., and Winnipeg, Man., will build a factory at Hamilton, Ont., on Rosslyn avenue. The company manufacture proprietary medicines, extracts, spices, toilet articles, stock remedies, disinfectants, etc. The first building will be 120 feet long by 60 feet deep, and five storeys high. Work will be started shortly, and Hamilton will be Canadian headquarters.

Halifax, N.S.—A petition for the winding-up of the Nova Scotia Car Works, was presented to the Supreme Court, on Oct. 15. It was ordered that the petition come up on Oct. 29 before the judge presiding at Chambers. Notice is given on behalf of the company that on Oct. 29 an application will be made for an order appointing the Eastern Trust Co., liquidator, that company having to-day been appointed liquidators. The plant is now engaged on an order for the 200 cars for the I. C. R.

Canadian Flour Mills Busy—Canadian milling companies have entered on another year under favorable auspices. Practically all mills are working to capacity now, and they have orders on their books from British and Foreign Governments that will keep them fully employed for at least two months to come. Two mills share in one Government order for 140,000 bags of flour. Certain mills are operating day and night. It is interesting to note, too, that Minneapolis mills in order to fill export orders have purchased considerable quantities of Canadian flour.

Dominion Development Commission—It is understood that Senator J. A. Lougheed, will be chairman of the Commision to be appointed by the Government to study a scheme of Canadian national development, with special reference to present conditions. It is further learned that William Smith, the member for South Ontario, and a well known stock breeder; J. C. Watters, the prominent labor man, of Ottawa; J. W. Flavelle, of Toronto; Dr. J. G. Rutherford, former Veterinary Director-General of Canada, and E. N. Hopkins, of Moose Jaw, a well known member of the Grain Growers' Association, have all been named as members of the commission, while other appointments are expected to be announced shortly.

Tenders Received on Big Pulp Limit.—The Ontario Government has received several tenders in response to its decision to offer for sale the Lac Seul or English River pulp limits north of Kenora. The limits were advertised some time ago, and offers were to be based upon strict conditions as to capital investment and paper output, similar to those imposed on the company that is now operating the immense plant at Iroquois Falls and turning out two hundred tons of print paper a day. Hon. G. Howard Ferguson, Minister of Lands, Forests and Mines, is now considering the tenders.

Lake Superior Corporation.—At the annual meeting of Lake Superior Corporation held last week the following were elected directors: Walter K. Whigham, Frederick McOwen, John T. Terry, Herbert Coppell, J. S. Dale, H. I. Underhill, W. E. Stavert, W. C. Franz, Alex. Taylor, James Hawson, A. H. Chitty and Thomas Gibson. At the meeting of the board, following the shareholders' meeting, officers were elected as follows: Chairman of board, W. K. Whigham; president, W. E. Stavert; vice-president, Herbert Coppell, W. C. Franz and James Hawson; secretary, Alex. Taylor; treasurer, James Hawson.

Mussens Ltd. Affairs.—Exchange of about $35,000 worth of stock for cash or bills receivable, without reduction of estimated surplus to creditors, is an encouraging note in a statement issued by the liquidator of Mussens Ltd. The six months extension granted by the court has just expired, and application will be made for further extension, as the showing made during the past six months would seem to warrant it. Of $131,000 bills receivable, $81,000 has been collected, and a considerable portion of the remainder is considered good. Stock amounting to $209,000 remains on hand, but can likely be sold for full value if time is given to do so. The liability to the bank is materially reduced, and a 10 per cent. dividend has been declared for the benefit of ordinary creditors. The liquidator, J. J. Robson, estimates that there is a surplus of $183,000, as assets exceed liabilities by that amount. Among the assets is an item of $66,750 equity in property in Montreal and other cities.

Catalogues

Plastic Boiler and Furnace Linings.—The C. B. Turner Co., Toronto, Ont., have issued a booklet dealing with plastic linings for boilers and furnaces. Directions for applying this lining are given and a list of users is included.

The Precision Instrument Co., Detroit Mich., have issued a set of bulletins describing an interesting line of measuring and recording apparatus for flue gases, etc. The bulletins deal successively with the Parker Co. machine, the "Simmance & Abady" combustion recorder, the "Simmance & Abady" "Precision" pressure and vacuum recorders

and indicators, "Precision" gauges, "Precision" efficiency kit, "Wright's" boiler tester and "Orsat" apparatus, the "Roland Wild" calorimeter, "Precision" water meter, "Simmance & Abady" encased thermometers. The principal features and method of operation of each apparatus are described fully especially as regards the CO_2 combustion recorder which is dealt with at considerable length. The bulletins contain price lists and code words and are fully illustrated. They are gotten up in an attractive manner and are bound together in a loose leaf folder.

Refractory Efficiency Engineering is the title of a 42-page booklet presented to the firebrick trade by the Elk Firebrick Co. of Canada, Hamilton, Ont., with the idea of bringing to the attention of the consumer a few facts concerning firebrick that it is hoped will prove beneficial to all concerned. The booklet is arranged in two parts. The first contains a brief description of the manufacture of firebrick from the mining of the fire-clay to the selling and loading of the products, including a description of the various processes. The second part deals more particularly with the company's products and includes references to the clays and equipment used, brands of firebrick and methods of sorting. Mention is also made in this section of the company's engineering department and policy. A number of ordinary special shapes are illustrated with their dimensions, while the concluding pages contain a number of useful mechanical tables for the trade.

Book Reviews

Northern Pacific Ports is the title of a book compiled and published by the Terminal Publishing Co., Inc., San Francisco, Cal. This is the second edition and the contents consist of useful marine, exporting and importing information for Alaska and the western coasts of Canada and the United States. The book contains a great deal of useful information for shipping concerns, traders, port authorities, etc. Brief mention of some of the subjects dealt with will give an idea of the scope of this publication. These are as follows:—Navigation laws of the United States, particulars of the various ports along the seaboard of the North Pacific including their harbor rules and regulations, list of transportation companies and their fleets, matters pertaining to Canadian and United States customs, currency tables, Rule of the Road at Sea, etc. The book contains 44 pages of reading matter printed in clear type with index and is bound in substantial cloth covers.

Thread Milling Machines

For High Explosive Shells

Designed for the purpose of milling the thread in the base and nose of high explosive shells.

Shell is placed inside a revolving spindle and is self-centering. A perfect thread is produced in base of shell in approximately 2½ minutes.

Milling Cutter is made from best high-speed steel, by Brown & Sharpe, from special design by Holden-Morgan Co., and is so shaped that it can be sharpened without changing the form. Cutter is designed to mill the top of thread as well as the depth.

Machines are fully equipped for work, including oil pump. Fitted with automatic stop motion, which stops machine when thread is completed. One operator can run several machines. Eliminates all risk of having shells rejected on account of thread being stripped, as is liable to be the case when tapped by the old method.

Write for complete particulars, prices, etc.

THE HOLDEN-MORGAN CO., Limited

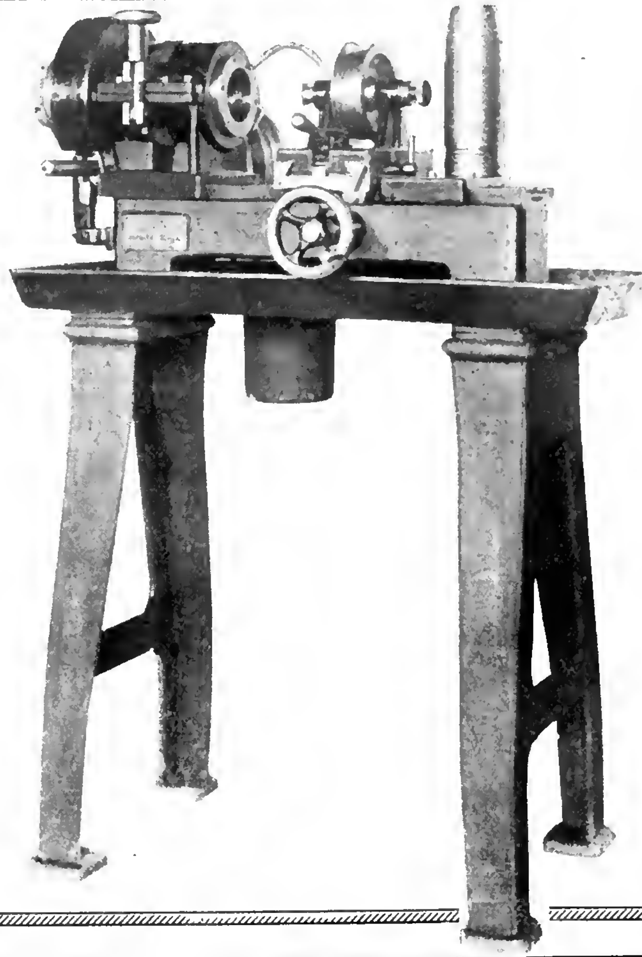
539 Richmond Street West, Toronto, Canada

SALES AGENTS:

The A. R. Williams Machinery Company, Limited

Toronto, Ontario

IF IT'S MACHINERY—WRITE "WILLIAMS."



Thousands of Threaded Pieces Each Day with a Geometric Threading Machine

RAPID AND PERFECT DUPLICATION

Takes floor space 2 ft. x 3 ft., and is complete with countershaft, change speed gear for adapting speed of spindle to diameter to be threaded; adjustable stop for gauging length of work.

No rough threads with the Geometric. They are as true and clean as can be produced by any screw machine.

Note the range:—Regularly, ¼-in. to ¾-in. Specially, ½-in. Std. pipe threads; ⅞-in. S.A.E. Std. Spark Plug threads, and up to 2-in. Diam. threads where the pitch is fine. Internal threads, ⅛-in. to 2-in.

Send in your Specifications and learn what we can do for you.

THE GEOMETRIC TOOL COMPANY

NEW HAVEN, CONN., U.S.A.

Canadian Agents: Williams & Wilson, Ltd., Montreal; The A. R. Williams Machinery Co., Ltd., Toronto, Winnipeg and St. John, N.B.

at $24.50, f.o.b. Pittsburgh. Wire rods are higher at $32 Pittsburgh.

Pig Iron

A large tonnage of low phosphorus pig iron is being imported from the States for steel making. Foundry grades are not so active but have advanced in price. Hamilton and Victoria brands are now quoted at $21 per ton, Toronto. Standard low phosphorus is being quoted $26 at furnace.

Old Material

The market is dull, there being little demand for domestic material with the exception of aluminum, which is very scarce. Buying is of a speculative order and consumers are slow in taking deliveries. Prices are firmer and higher for some materials. Scrap copper has advanced 25c to 50c per 100 lbs. according to grade. No. 1 composition turnings are now quoted at $10. Heavy melting steel is in fair demand and has advanced to $9.50, while machinery cast iron is also higher at $12.

Machine Tools

There is little change to note in the machine tool situation although there will be considerable activity when the orders for the larger calibre shells have been placed. Tenders are being submitted by manufacturers for these shells and the orders will no doubt be placed with as little delay as possible. The shells will be 6-in., 8-in. and 9-in., and heavy lathes will be required to machine them. There is still a steady although lighter demand for tools for 18-pdr. shells, together with a fair movement in second-hand equipment.

Supplies

There is a general upward tendency in prices, and a number of changes have to be noted this week. Discounts on twist drills have been revised. Carbon drills up to 1½ in. are now 55 p.c. and blacksmith 55 p.c. French medal glue is lower at 15c per pound. Gasoline has advanced 2c and is now quoted at 20c per gallon in barrel lots, while benzine is also higher at 18½c per gallon. Owing to a shortage in supplies, turpentine has advanced 5c and is now quoted at 70c. Linseed oil is also higher at 77c for raw and 80c for boiled oil. Plumbers' oakum is being quoted at $4.25 per 100 lbs., and lead wool is now 11c per pound. Business in supplies for shell plants continues active.

Metal Market

The metal market is dull, but prices are keeping steady. The sterling exchange situation, although somewhat easier, continues to have a depressing effect on the metal market. The New York market has been more active recently and is showing a tendency to react in an upward direction. The London market is quiet and steady. The scarcity of aluminum continues and prices have an upward tendency. Spelter is a little higher due to strength in both London and New York. The copper market is easier but, with the recent large new orders for munitions, a buying movement is expected with a possible advance in price. The tin market is firm but unchanged. Antimony and lead are firm but unchanged.

Tin.—The market is firm but quiet. The uncertainty of the British export-tax question has restrained activity and probably prevented a good movement. Tin is unchanged at 37c per pound.

Copper.—The market is dull and easier but prices are unchanged. The copper position, however, is a strong one as large orders for munitions continue to be placed which will result in a heavy demand for this metal. Consumers are buying on a hand-to-mouth basis, but may be forced to cover their requirements in a rising market. Producers seem to be in control of the situation, and, as copper must be had by munition manufacturers, higher prices are therefore more probable than otherwise. Locally copper is unchanged at 19½c per pound.

Spelter.—The market is higher both in London and New York, and the situation has improved. Spelter has advanced ½c locally and is now quoted at 17½c per pound.

Lead—The market is firm with the "Trust" price at $4.75 New York. Local quotations are unchanged at 6¼c per pound.

Antimony.—The market is very firm, and there is a scarcity of spot metal. Quotations are unchanged at 35c per pound.

Aluminum.—Prices are nominally unchanged, but the scarcity of this metal is rather more apparent, and holders are inclined to ask higher prices. Local quotations are nominal at 60c per pound.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Messrs. S. Ruperti and Alexsieff, care Military Attache, Russian Embassy, Washington, D.C.

St. John, N.B., October.—Industrial conditions in the Eastern provinces appear to be of a satisfactory nature, holding out much promise for the approaching winter, although there is no effort at expansion in any particular line. The only new extensions being instituted by established companies are for the manufacture of war supplies, and it is hoped that before next spring more orders will be received, if orders are still necessary for the success of the allied arms. The foundries in which shell manufacture is going on are for the most part working night and day in their efforts to expedite the output.

A new lumber mill at Nelson, on the Miramichi River, is to be erected this fall by Frasers, Ltd., according to a recent announcement. It is understood that the firm plans to expend between $80,000 and $100,000 on the new plant.

A new steel bridge at Grand Falls, the gully near the C. P. R. station, is to be erected. Plans and specifications are to be made this winter.

Local manufacturers and members of industrial concerns were instrumental in the success of a big endeavor recently held here—"a $50,000 patriotic auction" in the interests of the patriotic fund. They donated freely towards the movement, the gifts being sold and the profits going to the fund. Among the more interesting articles offered for sale were a number of nickel-plated shrapnel shell electric table lamps, these having been donated by the Phoenix Foundries.

CANADIAN CROP REPORT

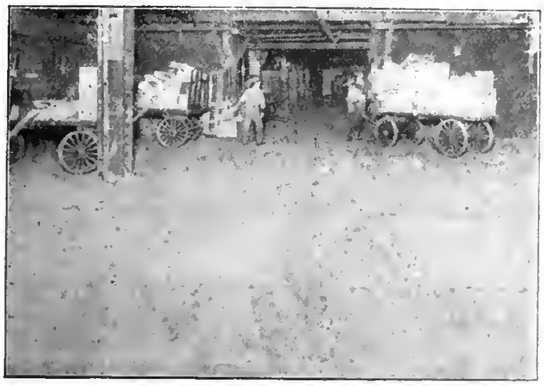
THE immensity of Canada's wheat crop this year is shown by the report sent out on October 15. For wheat, oats, rye and flax the yields are even higher than those reported a month ago, but in the case of barley and oats the present estimate is less than that of August 31st.

The total wheat crop of Canada is now placed at 336,258,000 bushels from 12,986,400 acres, representing an average yield per acre of 25.89 bushels. This total is 174,978,000 bushels more than last year's inferior yield of 161,280,000 bushels, the crop this year being, therefore, more than double, or 108 per cent. more than that of last year. It is 104,541,000 bushels, or 45 per cent. in excess of the previous highest yield of 231,717,000 bushels in 1913, and 140,232,000 bushels or 72 per cent. in excess of the annual average yield of 196,026,000 bushels for the five years, 1910 to 1914.

JOHNS-MANVILLE SERVICE COVERS THE CONTINENT

JOHNS-MANVILLE stands for a new order of Service—service that concerns itself with your problems and their solution—a service that is as responsible in fact as it is in name because it is backed up by J-M Responsibility.

The oldest genuine asphalt street in your town will show you how J-M Mastic Flooring lasts



U.S. Express Room, La Salle St. Station, Chicago, J-M Mastic Flooring. Graham, Burnham & Co., Architects, Chicago.

J-M Waterproof Mastic Flooring wears, because its basic material is Trinidad Lake Asphalt, which has stood the test of city street traffic for nearly fifty years. There is practically no wear-out to it in shop floor service.

J-M Mastic Flooring is as "springy" as wood. It can be laid in any consistency from hard-as-oak to soft-as-pine, according to requirements. It wears like iron, but is unlike flooring made of perfectly rigid material. It is absolutely dry, easy under foot, slip-proof and noiseless.

This flooring originates no dust to damage goods or injure machinery and, as it is waterproof, it can be cleaned and kept in sanitary condition by flushing. Acids and alkalies have no effect on it. Easily patched when resetting of machinery makes patching necessary. Can be applied over any stable foundation, anywhere, or over flooring now in place.

Let our flooring specialists see you about *your* floors.

J-M Asbestos Built-up Roofing is weather-proof, fire-resistant, non-corrosive and time-defying

This is not mere "selling talk," it is a statement of fact backed up by the performance of hundreds of J-M Asbestos Built-up Roofs in effective service for many years and still good for as many more.

The base of our built-up roofing is J-M Asbestos Ready-Roofing, even one ply of which would be practically as permanent as the brick walls or any other inorganic part of a building except for wind pressures, roof movement, damage from rough usage, etc. When built up by three- and four-ply laminations into thicknesses capable of resisting such strains, it furnishes a strong, light-weight, smooth-surface, practically fireproof roofing that never needs painting or any other attention and is bound to give perfect roofing service for a maximum period under the rule of J-M Roofing Responsibility. J-M Asbestos Built-up Roofing is examined, approved and labelled by the Underwriter's Laboratories, Inc., under the direction of the National Board of Fire Underwriters. It is given class "A" rating when laid over non-combustible roof decks having inclines not exceeding 3 inches to the foot and secures class "B" rating when laid over non-combustible roof decks having inclines not exceeding 6 inches to the foot.

Canadian Pacific Railway, Train Sheds, Windsor St. Station, Montreal, J-M Asbestos Roofings. The Dominion Bridge Co. and Geo. A. Fuller Construction Co., Contractors.

The Canadian H. W. Johns-Manville Co., Limited

Toronto Montreal Winnipeg Vancouver

330

Of oats, the revised total yield is 181,035,500 bushels from 11,365,000 acres, an average per acre of 42.33 bushels.

Barley comes out at 50,868,000 bushels from 1,509,350 acres, an average per acre of 33.70 bushels.

Rye is now 2,478,500 bushels from 112,300 acres, or 22.07 bushels per acre, and flaxseed 12,604,700 bushels from 1,009,600 acres, or 12.48 bushels per acre.

In the three North-west provinces, the estimated yield of wheat is 304,200,000 bushels, and of oats 305,680,000 bushels.

The remaining grain crops of Canada, whose yields are now reported on for the first time this year, are as follows: Peas, 3,240,400 bushels; beans, 594,000 bushels; buckwheat, 8,101,000 bushels; mixed grains, 17,128,500 bushels, and corn for husking, 14,594,000 bushels.

The condition of wheat, oats, grain varies from 90 and 93 per cent. of the standard quality fixed at 100.

ONTARIO MINES OUTPUT

THE output of the metalliferous mines and works of Ontario for the six months ending June 30, 1915, as reported to the Ontario Bureau of Mines, is shown by the following table, which also gives the production for the corresponding period of last year:

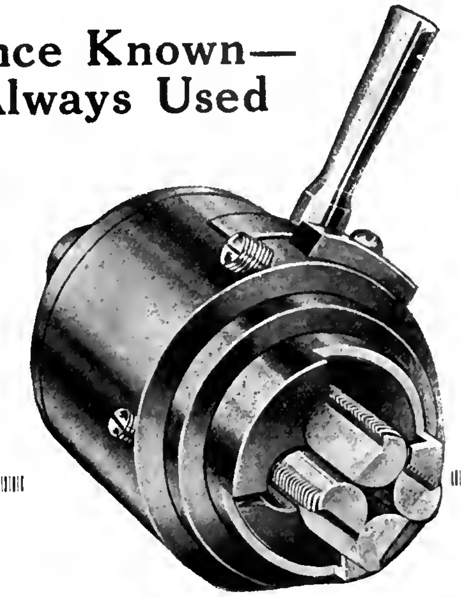
	6 months 1915	6 months 1914
Gold	$3,570,072	$2,011,069
Silver	5,188,763	7,053,418
Copper	1,229,894	1,197,059
Nickel	3,393,528	2,872,843
Iron Ore	288,296	118,119
Pig iron	2,856,040	4,429,664
Cobalt	34,443	22,581
Cobalt oxide (including nickel oxide)	56,812	379,152

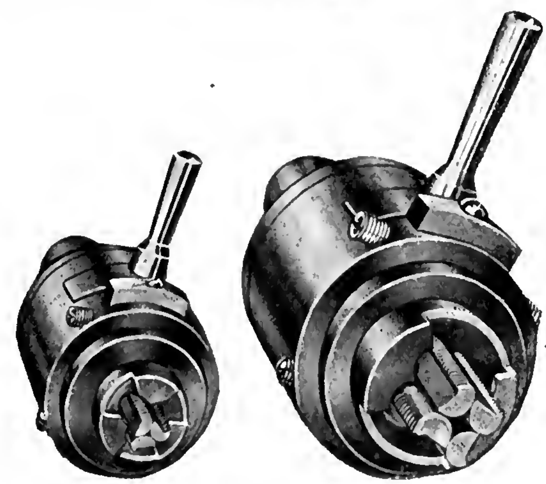
PAPER TRADE EXPANSION

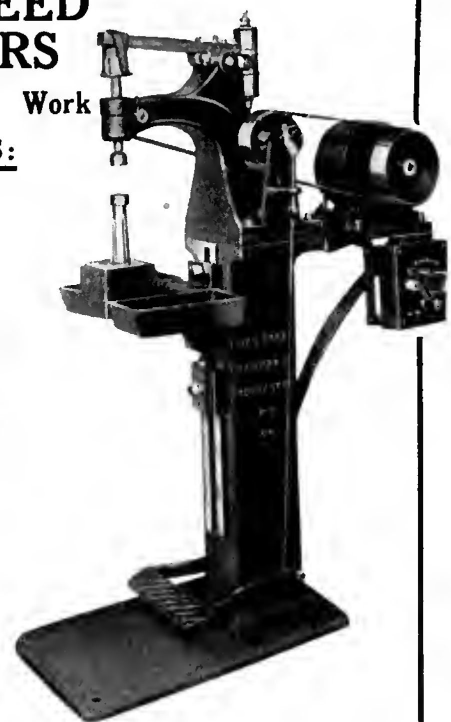
THE Canadian pulp and paper industry is evidently prospering. Since the opening of the current fiscal year exports to the United States especially have grown. July Government returns show exports of newsprint to the United States of $1,274,000. The export business of Canadian mills for the first four months, April to July, aggregated $5,098,799, of which the United States accounted for $4,589,144.

While the total compares with $4,213,000 in 1914, only $2,176,000 went across the border that year. As an indication of recent growth, this year's business so far is almost equal to eight months' business in 1913, and surpasses eight months' business in 1912, the total then being only $3,110,000. While the United States is Canada's best customer, the statement points out that another encouraging feature of the trade is the growing trade within the Empire.

For the fiscal year 1913-14 the total exports were $8,030,000, for 1914-15, $12,600,000, while the rate of the four months this year is between $15,000,000 and $16,000,000 per annum.







INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

St. Mary's Ont.—The Maxwell Works have received a large order for plugs for shells.

Vancouver, B.C.—The British Columbia Electric Railway Co. will make extensions to its cable plant.

Fort William, Ont.—The Canadian Car and Foundry Co. have started construction work on a new foundry.

London, Ont.—The George H. Belton Lumber Co. are considering installing electric motors for driving the machinery.

Sarnia, Ont.—The Imperial Oil Co. are installing several new steel tanks, the largest will have a capacity of 40,000 barrels of oil.

Chatham, Ont.—Bids will be called for shortly by the city council for a boiler to replace the present electric light plant boiler. W. G. Merritt is clerk.

London, Ont.—E. Leonard & Sons contemplate the installation of electrical drive in its plant for operating lathes, planing machines, etc.

Montreal, Que.—The Canadian Gas Co. are in the market for a large quantity of 6-in. pipe line in connection with the natural gas development at St. Hilaire.

Victoria, B.C.—The Imperial Oil Co., which has a plant at Burrard Inlet, B.C., is building an island headquarters plant at Victoria, B.C. Work is going ahead on a wharf, seven tanks, a boilerhouse, warehouse, etc.

Montreal, Que.—The Nicholson Constructions Co. are building machine shops on St. Patrick Street for the Canadian Tube & Iron Co. and the Colonial Wire Manufacturing Co. The cost is estimated at $13,000.

Hamilton, Ont.—A temporary heating plant, to cost about $5,000, will be installed at the Mountain Hospital by the city council. Later a permanent plant will be constructed at a cost of $30.000. Plans will be prepared at once.

Walkerville, Ont. — The Dominion Stamping Co., are erecting an additional plant here. The building will be of steel construction and will comprise a die shop, hammer shop and machine shop. The cost is estimated at $100,000.

Vancouver, B.C.—It is reported that a large quantity of shells will be allotted to firms in this district. The Vancouver Engineering Works will distribute 300,000. The Victoria Machinery Depot will have 200,000, and 150,000 will be made in New Westminster.

Sherbrooke, Que.—The contract for the proposed gas plant has been awarded to the Western Gas Construction Co., for $30,980. The specifications, however, will be revised and submitted to Mr. Mann, of the Montreal Light, Heat & Power Co., for approval and further suggestions before the work is proceeded with. Ald. Brault is chairman of the Gas and Electric Committee.

Port Moody, B.C.—The clearing of the nine and one-half acre site on which the plant of the Port Moody Steel Works is to be erected has already been commenced. The site of the plant is approximately three-quarters of a mile north of the business centre of the town, at the head of the Inlet and adjacent to the North Arm line of the C. P. R. The city will guarantee the bonds of the company to the extent of $100,000.

Chatham, Ont.—At a meeting of the directors of the Dominion Sugar Co., of Wallaceburg, held here on Oct. 21, it was decided to start at once the erection of a million-dollar beet sugar factory in this city. The directors have been assured by representative citizens of Chatham that the city will pass a by-law granting the company a free site worth $18,000 and annex the property to the city and provide other minor inducements.

Electrical

Attwood, Ont.—The Elma Township Council are considering installing a hydro-electric system.

Weston, Ont.—Plans for the extension of the local Hydro system to Thistletown were completed at the meeting of the Weston Water, Power & Light Commission held on Oct. 19. The scheme has received the approval of the Etobicoke Township Council, and the work will start within a few days.

Municipal

Kingston, Ont.—The Board of Works has decided to call for tenders for a concrete and asphalt mixing plant.

Beverley Township, Ont.—The township council have decided to build an electric power plant to cost $5,000.

Watrous, Sask.—A by-law will be voted on shortly to authorize the expenditure of $3,000 on water main extensions.

Montreal, Que.—The erection of a transformer building at the Low Level pumping station is being considered by the City Council. Tenders will probably be called shortly.

Sarnia, Ont.—At a recent meeting of the City Council a communication was read from the Sarnia Gas & Electric Light Co., offering to sell their electric light plant to the city for $175,000.

Port Moody, B.C.—The ratepayers have carried a by-law to guarantee the debentures of the Port Moody Steel Works to the extent of $100,000. The construction of the company's plant and rolling mills will be commenced shortly.

Niagara Falls

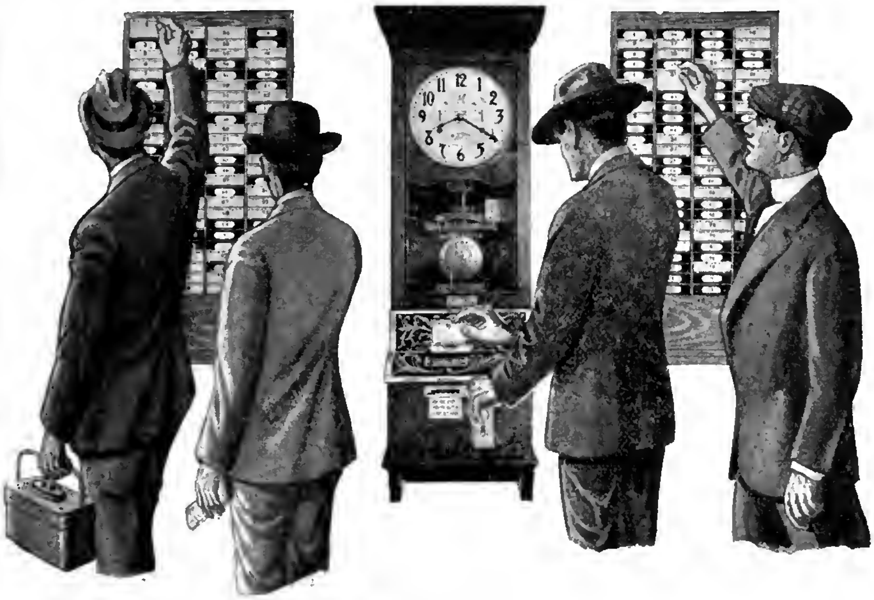
~~Welland~~, Ont.—A by-law will be submitted to the ratepayers on November 3rd providing for the purchase of power from the Hydro-Electric Commission and for the issue of debentures to the amount of $14,000 for machinery and equipment for the town electric station.

Windsor, Ont.—A company is being formed to build a waterworks system at Tecumseh at a cost of about $25,000. Part of the cost has been subscribed and the Government will be asked to issue a charter under the name of the Tecumseh and District Waterworks Corporation.

Midland, Ont.—The eastern end of James Playfair & Co. lumber yard at the waterfront, containing about 10,000,000 feet of lumber, was burned on Oct. 24. The fire also burned the coal dock underneath the coal for about 100 feet, the coal sliding into the bay. The estimated loss is $325,000.

Orillia, Ont.—The Town Council have decided to submit a by-law to the people on November 17 to raise by debenture $50,000 for the purpose of reconstructing the municipal building recently destroyed by fire. The new building will cost approximately $70,000, of which $20,000 is on hand from insurance.

Sarnia, Ont.—At a meeting of the City Council, held recently, the hydro-electric by-law and the by-law to provide for the purchase of the Electric Light Co.'s



Save the minutes, and save your profits –

The individual time card each employee is using shows in plain figures the exact time each employee comes in or goes out. The late arrivals and early leavings are printed in RED. This RED record stands out so prominently, it has proven itself very effective. This is the only original payroll entry in the world that the employee makes himself which he can see at time of making.

The International Time-Card Recording System

gives the employee confidence in his firm's methods. He knows that his time figures are correct. The employer saves on the hundreds and thousands of lost minutes that slip away when the employees' time is not properly recorded. Don't throw away time, for time is money! International Time Recording Systems are the result of thirty years' experience. The International Time Recording Co. supply 90% of all Time Recording Systems throughout the world. The reason—MERIT!

AMALGAMATED AMMUNITION - - MACHINERY

Does the work fast and beautifully
Quick deliveries guaranteed

A complete line of machinery in two sizes for all roughing and finishing operations in the manufacture of all sizes of High Explosive and Shrapnel shells from forgings or bar stock.

Amalgamated Ammunition machines are especially designed for their purpose, but will be found of permanent value in any shop which handles repetition work.

Owing to the ingeniously simple and strong design of our machines and the special provision which has been made by our fine organization for quantity production, we can guarantee attractively quick deliveries.

TO FACILITATE FULL RESPONSE TO INQUIRIES, PLEASE GIVE ALL POSSIBLE DETAILS OF YOUR REQUIREMENTS.

Amalgamated Machinery Corporation

72 West Adams Street, Chicago, U.S.A.

plant were given first and second readings. It was also decided that the vote of the ratepayers on the hydro-electric by-law be taken at the municipal elections in January.

General Industrial

Victoria, B.C.—The Victoria Chemical Co. will build an addition to their plant at the Outer wharf.

Redcliff, Alta.—The Alberta Pacific Grain Elevator Co., of Calgary, may build a new elevator here.

At. Ann's, C. B. — The Cape Breton Pulp Co., whose plant was recently destroyed by fire, will rebuild immediately.

Windsor, Ont.—The National Spring & Wire Co., are considering the erection of a new plant adjoining the present building. The firm make cushion springs for automobiles.

Hespeler, Ont.—A Buffalo, N.Y., concern propose establishing a plant here for making refrigerators. The company will occupy part of the plant of the Stamped Enamelled Ware Co.

Verdun, Que.—J. P. Cote, of Maisonneuve, will build a shoe factory here at a cost of $25,000, exclusive of the site. A by-law will be voted on to grant exemption of taxes and a low rate for power.

Picton, Ont.—The apple evaporator owned by L. K. Shourds at the Village of Wellington, was destroyed by fire on Oct. 18. The building and nearly all the contents were a total loss, with no insurance.

Brantford, Ont.—The Brantford Cordage Co. has commenced building operations on an addition, which will double the present capacity. The entire plant will be operated by electric power. The company will also erect a plant at Winnipeg.

Personal

W. B. Redfern, town engineer of Steelton, Ont., has resigned.

John C. MacDonald, former president of the MacDonald-Godson Co., iron founders and structural steel, died on Oct. 5 at the age of 66.

Capt. Thomas C. Irving, of the 2nd Field Company of Canadian Engineers, and vice-president of the Robert W. Hunt Co., Toronto, has been promoted to the rank of major.

D. M. Medcalf, chief inspector of boilers for the Province of Ontario, has returned to Toronto from an extended visit to the West, and also to the Panama-Pacific Exhibition at San Francisco, Cal.

Tenders

Toronto, Ont.—Tenders for lead covered cable, addressed to the chairman of the Toronto Electric Commissioners, will be received until Tuesday, November 16, 1915. Specifications and form of tender can be obtained at the office of the purchasing agent, 15 Wilton avenue.

Toronto, Ont.—Tenders will be received, addressed to the Chairman, Board of Control, City Hall, up to Tuesday, November 9, 1915, for the supply of a radial drill for machine shop, Danforth Avenue car barns. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

Toronto, Ont.—Tenders will be received, addressed to the Chairman, Board of Control, City Hall, Toronto, up to Tuesday, November 9, 1915, for the supply and erection of valves, steam piping, special steel castings and lagging, for main pumping station. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

Ottawa, Ont.—Tenders will be received until Wednesday, November 10, 1915, for the construction of steel gates, towers and operating machinery for the regulating dam, Big Chaudiere Falls, French River, Ont. Plans and form of contract can be seen and specification and forms of tender obtained at the Department of Public Works, Ottawa, and at the offices of the District Engineers, Confederation Life Building, Toronto, and Shaughnessy Building, Montreal.

Ottawa, Ont.—Tenders will be received up to Tuesday, November the 23rd, for the undermentioned items for delivery to H.M.C. Dockyards at Halifax, N.S., and Esquimalt, B.C.: Steel and iron bolts, nuts and rivets, electric cable and wire, mineral grease, castile soap, hard soap, turpentine, chemicals, cleansing powder, bunting. Forms of tender and all information may be obtained by application to the Naval Store Officer at H.M.C. Dockyards at Halifax, N.S., or Esquimalt, B.C., or to G. J. Desbarats, Deputy Minister of the Naval Service, Ottawa.

Contracts Awarded

Montreal, Que.—Masson Co., of Quebec, will supply the steel work for the Star Boiler and Radiator Co.'s new factory.

Esquimalt, B.C.—The contract for the construction of an oil storage plant for the Imperial Oil Co. has been let to the Taylor Engineering Co., Vancouver, at $40,000.

St. Lambert, Que.—The Town Council has awarded the contract for ornamental street lighting to G. M. Gest, of Montreal, at $4,250. E. Drinkwater is town engineer.

London, Ont.—The contract for the steel work for the new shops for the London and Port Stanley Railway has been let to McGregor & McIntyre, Toronto, at $10,000.

Markham, Ont.—The contracts for the new waterworks scheme have now almost all been awarded. The National Iron Works have been given the contract for the pipes, hydrants and valves. The Pittsburg and Desmoines Steel Co. are to erect the elevated tanks at a cost of $5,750. The contract for pipe laying has not yet been awarded.

Trade Gossip

Welland, Ont.—The Electric Steel & Metals Co. will install a 6-ton Heroult furnace for making steel castings.

St. Thomas, Ont.—The local plant of the Canada Iron Corporation has received an order for a large number of iron plugs for shells.

The Morgan Engineering Co., Alliance, Ohio, have sold a 60-ton double trolley ladle crane to the Algoma Steel Corporation, Sault Ste. Marie, Ont.

The Northern Crane Works, of Walkerville, Ont., report the sale of several electric traveling cranes to the Consolidated Mining & Smelting Co., at Trail British Columbia.

The Canadian Bridge Co. has been incorporated at Ottawa with a capital of $2,000,000 to take over the structural steel business of the Canadian Bridge Co. of Walkerville, Ont., a provincial corporation.

The Canadian Fairbanks-Morse Co. will conduct their machine tool department from the Toronto office on Front Street. F. W. Evans has been transferred from Montreal, and will continue in charge of this department.

Galt, Ont.—The Galt Machine Screw Co., are about to commence the construction of a new factory. The building will be of mill construction with brick walls, and concrete basement and floors. The plant will be one of the best equipped in the province, and will be completed about the end of this year. Mr. Jansen is the general manager.

Chippawa, Ont.—The Norton Co. will erect a new electric furnace abrasive plant for the manufacture of alundum adjacent to their crystolon plant. The plant will consist of an office building, a building for housing the electric furnaces, mixing and storage bins, etc., and a reinforced concrete storage building. Six electric furnaces will be installed at once with a 15-ton overhead travelling crane, motors and other electrical equipment.

Building Notes

Montreal, Que.—The Canadian Iron Tube Co., have obtained a permit for the erection of a building in Hamilton to cost $2,000.

Montreal, Que.—A permit has been issued to the Thos. Davidson Mfg. Co., for the erection of a factory extension to cost $1,000.

Toronto, Ont.—The public school which will be erected on Sydenham street, will cost about $182,000. Tenders have been opened.

Toronto, Ont.—The Pharmacal Co., has applied to the city architect for a permit to build an addition to their factory on Brockton Ave., to cost $7,000.

Montreal, Que.—The Marcil Trust Co. purpose erecting an office building on St. James street. Edward & W. S. Maxwell, of this city, are the architects.

Orillia, Ont.—The town council have accepted the plans for the proposed municipal buildings, prepared by Burke, Horwood & White, architects of Toronto. The cost is estimated at $70,000.

Quebec, Que.—A building permit has been issued to the Public Service Corporation for an extension to the power house to cost $1,800, and the construction of a warehouse to cost $2,500.

Toronto, Ont.—Work will begin shortly on the Imperial Oil Co.'s new building at the corner of Court and Church streets. The structure will be 115 ft x 76 ft., and ten stories high. It will be of steel construction with limestone exterior.

Wood-Working

Bury, Que.—L. H. Martin will build a sawmill to cost about $10,000.

Vancouver, B.C.—A. B. Cahoon, Cedar Rapids, Mich., is contemplating building a furniture factory here.

Montreal, Que.—Fire destroyed the carriage factory owned by S. H. Chapleau, on Oct. 18, doing several thousand dollars damage.

Baie Verte, N.B.—Fire on Oct. 5 destroyed Capt. E. R. Woods' cooperage. The damage is estimated at $1,500, inclusive of machinery.

PROFESSIONAL DIRECTORY

If what you want is not advertised in this issue consult the Buyers' Directory at the back.

Marine

Ottawa, Ont.—Engineers who have been at work on the Toronto harbor situation have completed their report for submission to the Minister of Public Works. The work will be made good and construction will be proceeded with without delay.

Montreal, Que.—The Dominion Coal Co. has abandoned hope for the safety of its colliers, Kron Prinz Olav and Easington, which left Sydney, N.S., on Sept. 25, the former for Montreal and the latter for St. John, N.B. The two ships ran into a hurricane on Sept. 26. The Kron Prinz Olav had a crew of 23 men and the Easington carried 20 men.

Canada Steamship Lines.—J. W. Norcross, vice-president and managing director Canada Steamship Lines, states that the record rates for transport of grain on the Great Lakes and Transatlantic will have a favorable influence on the result of the company's earnings this year. Arrangements have been made, Mr. Norcross said, for the chartering of seventeen of the company's steamers for the entire winter, but would not state what rates had been secured except to say that the charters were favorable .

The Newfoundland Naval Reserve.—The total registration for the Newfoundland Royal Naval Reserve to date is 1,200. Of these, 63 have laid down their lives for the Empire in active service, while others have died through natural causes and more invalided home. The total loss since the war began is approximately 100, so that the present fighting strength of the unit can be estimated at 1,100 men. Of these, 75 are in training on H.M.S. "Calypso" at St. John's, and the remainder on active service in the North Sea doing their duty by King and country.

Trinity, Newfoundland.—It is proposed to make this the winter shipping port of the Anglo-Newfoundland Development Co., whose pulp and paper-making works are situated at Grand Falls. It is highly probable that will be carried to a successful termination, as the commercial people and others of the district have petitioned the Government to have the stub railway leading into the town completed and suitable piers erected. It will mean much, financially and otherwise, to all parties concerned. Mr. Scott, the company's manager, approves of the scheme, viewing it as he does that during the past few years their shipping port in Notre Dame Bay has during winter time been practically closed, inconveniencing as a result their shipment of products. Trinity is an ice free port all year round, besides a town of

considerable commercial standing in the district, of which it is the capital.

New Incorporations

The Dominion Brake Shoe Co., has obtained a Provincial license at Toronto to carry on business at St. Thomas, Ont., with a capital not to exceed $200,000.

The Circle Bar Knitting Co. has been incorporated at Ottawa with a capital of $100,000 to carry on a general knitting mill business at Kincardine, Ont. Incorporators: William Mitchell, James Malcolm and Walter G. Keebler, all of Kincardine, Ont.

The Morse Porcupine Syndicate has been incorporated at Toronto, Ont., with a capital of $35,000 to acquire and develop mines, mineral lands and deposits. Head office at Toronto: Incorporators: Elmer McLeod Rowand and Oscar Heuman King, of Toronto.

The Standard Steel Co., has been incorporated at Ottawa, with a capital of $200,000, to manufacture corrugated steel pipes, culverts, etc., at Montreal, Que. Incorporators: Louis Athanse David, Louis D'Argy Mailhiot and H. R. Bush, all of Montreal.

The Canadian Chadwick Metal Co. has been incorporated at Toronto with a capital of $40,000, to carry on the business of brass founders, iron founders, mechanical engineers, at Dundas, Ont. Incorporators, Arthur Burgess Turner and George Alexander Young, of Hamilton, Ont.

The Neely Rotary Engine Co. of Canada has been incorporated at Ottawa with a capital of $200,000 to manufacture engines, automobiles, trucks, machine tools, etc., at Toronto, Ont. Incorporators: Wilbut Fletcher Neely, John Whitfield and Arthur T. Lawson, all of Toronto.

The Laurentide Power Co. has been incorporated at Ottawa with a capital of $10,500,000 to carry on the business of an electric light, heat and power company. Head office at Montreal. Incorporators: Warwick Fielding Chipman, Walter Robert Shanks and F. G. Bush, all of Montreal.

St. Catharines Steel & Metal Co., has been incorporated at Toronto, Ont., with a capital of $50,000 to carry on the business of manufacturers of machinery, tools, ammunition of all kinds at St. Catharines, Ont. Incorporators: Harry Shortt and Henry H. Collier of St. Catharines, Ont.

The O'Brien Munitions, has been incorporated at Ottawa with a capital of $2,000,000 to carry on the business of mechanical, electrical and chemical en-

gineers, and to manufacture munitions of war at Renfrew, Ont. Incorporators: Robert George Code, Edmund Foster Burritt and Erwin C. Pixley, all of Ottawa, Ont.

The Specialty Machine Co. has been incorporated at Toronto, Ont., with a capital of $150,000 to carry on the business of iron founders, mechanical engineers and manufacturers of munitions, specialties, tools, etc., at Toroto. Incorporators: George McClure Willoughby, James Henry Fraser and Francis H. Hurley, all of Toronto.

Catalogues

Temperature Booster.—The W. E. Clark Co., Toronto, have issued a folder describing the Clark temperature booster. This is a device for increasing the circulation of the water in hot water heating systems. A full description covering the construction and method of operation is given, accompanied by sectional views.

The Cowan Trucking System is the title of a catalogue issued by the Cowan Truck Co., Holyoke, Mass. This catalogue contains principally a number of testimonials with full-page half-tones showing the Cowan truck being used in a number of plants and for a variety of purposes. The concluding pages contain illustrations of the various types of this truck or transveyor, together with dimensions and descriptions, and also a list of replacement parts.

The Union Twist Drill Co., Athol, Mass., have published a "Book of Information" catalogue G, dealing with an extensive line of twist drills, reamers, gear and milling cutters, and machine tools which the company manufacture. The catalogue is divided into six sections each being devoted to a different product; there being also a separate index for each section. All the tools listed are illustrated and are accompanied by a brief description and dimensions. No. 1 or cutter section contains a lot of valuable information on gear cutters with formulae for determining the dimensions of gears by diametral pitch, cutting mitre and bevel gears, calculating diameters of sprocket wheels for block centre chains and cutting involute teeth, etc. The formulae are accompanied by diagrams of gear sections. The sixth and last section, in addition to matter relating to arbors, contains several useful mechanical tables on cutting speeds, decimal equivalents, tap drills, screw threads, etc. The catalogue is pocket size and contains 380 pages. It is a useful publication to have on file for reference.

Book Reviews

Products and By-products of Coal.—The Department of Mines, Ottawa, has issued Bulletin No. 323, dealing with products and by-products of coal. The object of this report is to satisfy, as far as possible, the increasing need for a monograph on fuel products and by-products. The subject, however, is so comprehensive that it is impossible—within the limits of a bulletin—to treat it other than in outline.

The subject matter of the present report is divided into two parts—(1) the production of coke, gas, ammonia, and tar from bituminous coal; (2) the properties and uses of these products and by-products. In setting forth the results of these investigations, the aim has been to give prominence to the commercial rather than to the scientific aspect of the subjects treated, especially as regards their bearing on existing conditions in Canada.

The present time is particularly opportune for discussing the question of establishing new lines of trade and commerce, for, on account of the deplorable war conditions in Europe, all industries are more or less dislocated as regards supply and demand, and manufacturers everywhere are taking stock of current conditions and future possibilities. The trade possibility, that would naturally occur to most people interested in the commercial development of Canada, is the establishment of a coal-tar dye industry; since here, as in other countries, factories using dyes are being seriously inconvenienced, owing to the fact that Germany—by a combination of scientific research, technical ability, and commercial energy—has for years had practically a monopoly in the manufacture and supply of coal-tar dyes; and consequently since the opening of the war importation of this commodity from Europe has almost ceased. Conditions, however, show that the importation of dyes into Canada is not large, and that the prospect of developing a flourishing coal-tar dye industry is not encouraging.

Nevertheless, there are other important by-products from coal which, although not figuring so prominently in the public eye, are of much greater importance commercially, and are also peculiarly suited for production in Canada.

Processes, plants, and methods are comprehensively described, such subjects as coke ovens, etc., with the resulting products, coke, gas, ammonia, and tar, being considered.

Concise information is given regarding the commercial products of coal tar, the first products from this substance and their field of industrial application being

of particular interest at the present moment.

Experience in Efficiency, by Benj. A. Franklin, 167 pages, 7½ in. x 5 in., published by the Engineering Magazine Co., New York. Price $1.00. This book is an addition to the Works Management Library, most of the chapters appearing originally in the Engineering Magazine. The book has been written as a reply to requests often made for specific examples of efficiency methods. The author takes as a basis the conditions prevailing in a certain factory, and after a close study of the situation proceeds to explain what was right or wrong and if the latter how it was corrected. He also explains how greater shop economies were effected and larger profits made without any change of organization or personnel. The book contains ten chapters. The first four are devoted to a description of methods for increasing both the output and quality of direct production, which is largely connected with the handling of labor. The fifth chapter extends the same principles to the treatment of clerical or as it is usually termed non-productive labor. The sixth chapter covers similar ground with the same applied ideas only on a larger scale so as to include the entire force. Organization rather than individuals is the theme of the next chapter while chapter eight deals with the reduction of factory expenses. An efficient cost system is outlined and developed in chapter nine while the concluding chapter dwells on the necessity of efficiency will. In this chapter it will be found that all the preceding measures are connected to and based upon the fundamental necessity of "efficiency will" as a driving force in the establishing of efficiency practice. The subject has been treated in a logical manner and shows clearly the character of the problem attacked and the nature of the solution found.

Tillsonburg, Ont.—A large auto firm of Detroit is negotiating with the directors of the Tillsonburg Electric Car Co., regarding securing its building for the purpose of manufacturing auto bodies.

Tenders

Toronto, Ont.—Tenders for lead covered cable, addressed to the chairman of the Toronto Electric Commissioners, will be received until Tuesday, November 16, 1915. Specifications and form of tender can be obtained at the office of the purchasing agent, 15 Wilton Avenue.

Toronto, Ont.—Tenders will be received, addressed to the Chairman, Board of Control, City Hall, up to Tuesday, November 9, 1915, for the supply of a radial drill for machine shop, Danforth Avenue car barns. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

Toronto, Ont.—Tenders for all trades required in connection with the erection of an incinerator building, bridges, etc., on the Don Roadway, will be received up to Tuesday, November 9. Plans and specifications may be seen and forms of tender and all information obtained at the office of the city architect, City Hall, Toronto.

Toronto, Ont.—Tenders will be received, addressed to the Chairman, Board of Control, City Hall, Toronto, up to Tuesday, November 9, 1915, for the supply and erection of valves, steam piping, special steel castings and lagging, for main pumping station. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

Ottawa, Ont.—Tenders will be received until Wednesday, November 10, 1915, for the construction of steel gates, towers and operating machinery for the regulating dam, Big Chaudiere Falls, French River, Ont. Plans and form of contract can be seen and specification and forms of tender obtained at the Department of Public Works, Ottawa, and at the offices of the District Engineers, Confederation Life Building, Toronto, and Shaughnessy Building, Montreal.

Ottawa, Ont.—Tenders will be received up to Tuesday, November the 23rd, for the undermentioned items for delivery to H.M.C. Dockyards at Halifax, N.S., and Esquimalt, B.C.: Steel and iron bolts, nuts and rivets, electric cable and wire, mineral grease, castile soap, hard soap, turpentine, chemicals, cleansing powder, bunting. Forms of tender and all information may be obtained by application to the Naval Store officer at H.M.C. Dockyards at Halifax, N.S., or Esquimalt, B.C., or to G. J. Desbarats, Deputy Minister of the Naval Service, Ottawa.

Contracts Awarded

Sherbrooke, Que.—The city council have awarded a contract for cast iron pipe to Codere & Sons Co.

Windsor, Ont.—The contract to install a new Scotch boiler in the waterworks has been awarded the International Engine Works, Montreal. The boiler, including installation, will cost about $5,000.

Toronto, Ont.—The Board of Control has awarded the contract to the Northern Crane Works, Ltd., for the supply and erection of an electric crane, hoist and single line clam shell bucket at the main sewage disposal works, for $3,580.

Personal

H. V. Armstrong, B.A.Sc., for several years town engineer of Estevan, Sask., has resigned.

H. Sydney Hancock, Junr., formerly city engineer of Fort William, Ont., has left for England.

H. T. Jackson, of Montreal, has been appointed to the position of manager of the Record Foundry & Machine Co., Moncton, N.B.

Lieut. Herrick Duggan of the Royal Engineers, and until recently on the staff of the Dominion Bridge Co., Lachine, Que., has been wounded in France.

David A. Thomas, representative of the British Minister of Munitions, has left Ottawa for New York on his way back to England. His work is now in the hands of Lionel Hichens.

A. W. Smithers, chairman of the Board of Directors of the Grand Trunk Railway System, has arrived in Montreal from London, England, to consult with President E. J. Chamberlin. Mr. Smithers will not make his customary visit to the Coast.

P. Gifkins, general manager of the Dominion Atlantic Railway for the past fifteen years, and associated with the company for forty-four years, has retired. George E. Graham is the new general manager, with headquarters at Kentville, N. S. The change takes effect on November 1.

Geo. E. Graham, formerly superintendent of the British Columbia division of the C.P.R., and for the past two years general manager of the Coquitlam Terminal Co., has been appointed general manager of the Dominion Atlantic Railway, a subsidiary line of the C.P.R., operating in the Maritime Provinces.

Capt. Leon H. Curry of the 42nd Royal Highlanders, of Montreal, was killed in action recently in Northern France. Capt. Curry was born at Amherst, N.S., 30 years ago. About three years ago he was appointed assistant to the vice-president and general manager of the Canadian Steel Foundries, Montreal, Que.

Sir Charles Tupper, Bart., K.C.M.G., died in London, England, on Oct. 30, at the age of 94. Sir Charles was born at Amherst, N.S., on July 2, 1821, and in 1855 entered upon his public career. He was appointed Minister of Public Works in 1878, in the MacDonald Administration and afterwards he created the Department of Railways and Canals, and was its first Minister. It was while Minister of Railways and Canals that he carried out important works in connection with the enlargement of the Welland Canal, the deepening of the St. Lawrence, and the construction by private company of the Canadian Pacific Railway. Sir Charles Tupper was created a K.C.M.G. in 1879, a G. C.M.G. in 1886, a Baronet of the United Kingdom in 1888, and an Imperial Privy Councillor in 1908.

Sir Andrew Noble, Bart., K.C.B., the famous authority on artillery and explosives, and chairman of the Armstrong, Whitworth & Co., Newcastle-on-Tyne, England, died recently. Sir Andrew was born at Greenock, Scotland, in 1831. In 1860 he began his famous partnership with Lord Armstrong who had established a plant for making ordnance at Elswick. Later on the firm amalgamated with the Whitworth Co., the new concern being known as Armstrong, Whitworth & Co., which has developed into one of the greatest industrial establishments in the world. Sir Andrew received many honors. He was created a C. B. in 1881, and K. C. B. in 1893, and a Baronet of the United Kingdom in 1902. In 1870 he was elected a Fellow of the Royal Society; and in 1880 received the Royal Medal of that Society. He was a Knight of various foreign orders, and was honored by many learned and scientific bodies.

Trade Gossip

The Algoma Steel Co., of Sault Ste. Marie, Ont., has contracted to supply 30,000 tons of steel rounds to Great Britain. The company is also said to have closed orders for 20,000 additional rounds.

The Windsor Brass Foundry Co., Windsor, Ont., have purchased the Cana-

CLASSIFIED ADVERTISEMENTS

Rates (payable in advance):—2c per word first insertion, 1c per word subsequent insertion. 5c additional each insertion when Box Number is required. Each figure counts as one word.

FOR SALE

FOR SALE — NEW HAVEN SIXTY INCH face plate Lathe—fifteen foot bed, complete with countershaft, steady rest, etc. Excellent tool for boring and nosing shells. Cost thirty-five hundred—will take two thousand. Bancroft Lathe, ten inch swing, 5 ft. bed, screw cutting, good condition, $125. Winnipeg Machinery Exchange, Winnipeg. (21)

FOR SALE

FOR SALE—GAS ENGINE, 22 H.P., WITH Magneto, Battery, Water Tank, Gasometer, Muffler and 26" Clutch Pulley, cheap. This engine was used four months during the erection of our plant. The same is equipped for natural gas, but can be changed and used with gasoline at very reasonable expense. Well-known United States engine. Original cost, $600.00, besides the duty. Address H. Mueller Mfg. Co., Ltd., Sarnia, Ont. (21)

FOR SALE—ELECTRIC PASSENGER AND freight elevator plant. Patterns—Drawings—Blueprints—special and ordinary machinery and stock. This is a splendid business—few competitors. We offer a decided bargain. Winnipeg Machinery Exchange, Winnipeg. (21)

Advertising

"Advertising is the education of the public as to who you are, where you are, and what you have to offer in the way of skill, talent or commodity. The only man who should not advertise is the man who has nothing to offer the world in the way of commodity or service."—*Elbert Hubbard.*

dian manufacturing rights of the Harvey valve. The company are also putting on the market the "Bradley" auto sleeper.

Arnold Thompson, chief inspector and late foreman toolmaker with the Canadian Allis-Chalmers, Toronto, has resigned his position and will take over the Tobin Arms Factory at Woodstock, Ont. The firm will be known as the Arnold Thompson Tool Co., and the product will be jigs, tools and gauges, etc.

Montreal, Que.—A new subsidiary of the Dominion Bridge Co., of Lachine, Que., has just been incorporated at Ottawa, its purpose being to take up the manufacturing of brass discs for cartridge cases and copper bands for shells, an entirely new enterprise in Canada. The promoters of the new concern are G. H. Duggan and H. H. Vaughan, of the Montreal Ammunition Co. The Company is capitalized at $300,000 and the factory will be at Montreal.

Industrial Conditions Much Better.—A most gratifying report has been prepared by W. D. Lighthall, secretary of the Union of Canadian Municipalities. It was to the effect that after a thorough investigation into unemployment problems in all parts of the country, it would be unnecessary to call a Dominion-wide convention to discuss what could be done to help conditions. Most of the places, Mr. Lightall says, will be quite able to look after their own unemployed this year.

McLaughlin Carriage Co.—The deal between the Carriage Factories, Ltd., and the McLaughlin Carriage Co., of Oshawa, whereby the former concern takes over the entire carriage end of the McLaughlins has been closed. The McLaughlins will give their entire attention to the automobile trade. It is said that Carriage Factories, which is a Brockville concern, has secured the business on exceptionally favorable terms. The McLaughlin Company has secured the Canadian agency of the Chevrolet motor car, and this enlarged business will demand the company's energies formerly given to carriage manufacture.

New Incorporations

The Casey-Harris Mining Co., has been incorporated with a capital of $100,000, to acquire and develop mineral lands and deposits. Head office at Toronto.

The Diaphone Signal Company, has been incorporated at Ottawa with a capital of $825,000, to manufacture all kinds of signalling devices, at Toronto. Incorporators: Gideon Grant and Bruce Williams, both of Toronto.

STRIP STEEL

PLAIN steel sheets, black "Premier" Galvanized Sheets, Open-Hearth Drawing stock.

We can furnish these promptly and at lowest prices.

We carry an immense stock from ten to thirty gauge.

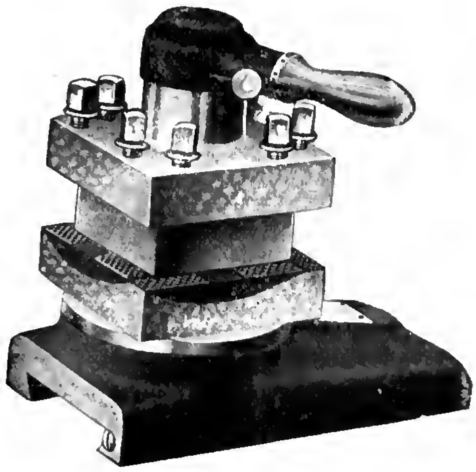
8 LOMBARD ST., TORONTO, CAN.

Making SHRAPNEL ?

Here is Standard Equipment

The Fay & Scott turret tool post shown here is being universally adopted as standard equipment for the manufacture of shrapnel.

The square head turret, style G, is used for turning the outside of the shell. We have made these turrets for years, and can fit them to any make or size of lathe, old or new.



Style G

Catalog and full details on request

Fay & Scott, Dexter, Me.

Renown Engine & Machine Co., has been incorporated at Ottawa with a capital of $50,000, to manufacture machinery of all kinds and war munitions, at Montreal. Incorporators: Alexander Ronald Johnson and Arthur Ross, of Montreal.

The Canadian Gahagan Construction Co., has been incorporated at Ottawa with a capital of $100,000 to carry on the business of general contractors, engineers, at Toronto. Incorporators: John Shirley Denison and Frank James Foley, of Toronto.

The Lachance Nut Lock Co., has been incorporated at Ottawa with a capital of $300,000, to manufacture the "Lachance" nut lock and other devices, at Montreal, Que. Incorporators: Joseph Alphones Bilodeau and Maurice Loranger, of Montreal.

The National Steel Products, has been incorporated at Ottawa with a capital of $100,000, to manufacture munitions, explosives, projectiles, shells, aeroplanes, guns and gun carriages, at Toronto, Ont. Incorporators: Thomas Gibson and Joseph Garfield Gibson, of Toronto.

The Eastern Machinery Co., of Montreal, has been incorporated at Ottawa with a capital of $45,000 to carry on the business of machinists, mechanical, electrical and civil engineers, at Montreal. Incorporators: Armand Lalonde and Emile Alphonse Lalonde, both of Montreal.

Steel and Radiation, Ltd., has been incorporated at Ottawa with a capital of $5,000,000, to manufacture iron, steel and other metals and to carry on the business of an engineering and construction company, at Toronto. Incorporators: James Steller Lovell, Robert Gowans and John Joseph Dashwood.

Catalogues

Safety Valves—The James Morrison Brass Mfg. Co., Toronto, have issued a bulletin illustrating and describing their line of safety valves for high and low pressures and super-heat steam. A price list is included for the various types.

Murphy, Stearman & Co., 180 Gray's Inn Road, London, England, have sent us a copy of their new catalogue. The goods dealt with are all British made and embrace complete equipment for foundries and machine shops, and many other lines for engineers and contractors.

The Canadian Allis-Chalmers, Ltd., Toronto, have issued a bulletin No. 1633 which describes a test of a low head hydraulic power plant at the Grand Rapids, Wis., station of the Centralia Pulp &

Water Co. The test gives some interesting data on hydro-electric plant operation, including a series of velocity curves.

Reducing Valves, made by the James Morrison Brass Mfg. Co., Toronto, Ont., are described fully in a folder recently issued. A sectional view is shown of the J. M. T. reducing valve, which is followed by a description covering the method of operation, and also directions for installing and cleaning. A price list is included, giving weights and dimensions of the various sizes.

Foundry Equipment.—The National Engineering Co. of Chicago, Ill., have issued a bulletin dealing with the "Simpson" intensive foundry mixer and "Simpson" national screen separator. The construction of the mixer and methods of handling various materials are fully described, while illustrations give a general idea of the machine. The screen separator is also described and illustrated.

"The Cost of Pumping Water" is the title of a collection of graphical charts with accompanying explanatory text issued by the DeLaval Steam Turbine Co., of Trenton, N.J. The object of the publication is to facilitate computation of the overall economy of different types of steam pumping units, having given the cost of fuel, steam pressure, rate of interest, cost of apparatus and other variables. The first chart shows the number of B.t.u., represented by each pound of steam for various combinations of superheat, steam pressure and feed water temperature. The second chart gives the cost of 1,000 lbs. of steam and the cost of a million B.t.u.'s in the steam from the cost of coal per ton, the heat value of the coal and the boiler efficiency. The third diagram shows the relation existing between the average cost of steam-turbine-driven centrifugal pumping units and the head pumped against. The fourth diagram shows the amount of money to be set aside yearly for sinking fund, to cover depreciation for different terms of life and rates of interest. The fifth diagram is the well known Mollier steam chart, supplemented by a convenient scale by means of which B.t.u. available per pound between given limits, the resulting velocity of steam in feet per second and the corresponding duty in foot pounds per 1,000 lbs. of steam, and the pounds of steam per h.p. hour may be read off directly. The sixth diagram is an alignment chart for determining the resistance of pipes to flow of water. Three scales represent gallons per minute, diameter of pipe in inches, and loss of head in feet per 1,000 ft. of pipe. A straight edge laid across points corresponding to known figures on two of the scales, shows the third variable by intersection with the remaining scale. At the end of the publication a list of representative municipal installations of De Laval steam-turbine-driven centrifugal pumps, from which it is to be observed that units of this type have been installed for capacities as large as 100,000,000 gallons per day and heads as great as 334 ft., and have developed duties exceeding 150,000,000 ft., lbs. per 1,000 lbs. of steam. It is also pointed out that because of the low first cost of apparatus, foundations and buildings inherent in this type of pump, the total cost of pumping water is greatly reduced as compared with the much larger, heavier and more expensive triple-expansion reciprocating pumping engines, in spite of the somewhat higher duty exhibited by the latter. Copies of the publication are offered gratis to those interested.

Book Reviews

The Influence of Temperature Upon the Strength of Concrete, by A. B. McDaniel, has been issued as Bulletin No. 81 of the Engineering Experiment Station of the University of Illinois. This bulletin presents a study of the data obtained from three series of tests of concrete cubes and cylinders. These specimens were stored under temperature conditions varying from 25 deg. to 90 deg. F., and were tested at various ages up to twenty-eight days. Curves are presented to show the relation between strength and age for different temperature conditions, and also the relation between strength and temperature at different ages. The results are summarized in a set of curves which show the percentage strength of concrete at different ages and under different temperature conditions to that at an age of twenty-eight days and under a normal temperature of 70 deg. F. The results of the tests made under freezing temperature conditions are of especial interest; showing the gradual and slow gain in strength under a storage temperature slightly below freezing, and the disintegrating effect of alternate thawing and freezing temperatures. The bulletin will be of value to the contractor, engineer and others engaged or interested in construction work for information regarding the strength which may be expected of ordinary concrete under different age and temperature conditions and the time for the removal of the forms. Copies of Bulletin No. 81 may be obtained gratis upon application to W. F. M. Goss, Director of the Engineering Experiment Station, University of Illinois, Urbana, Ill.

Personal

City Engineer Mellis Ferguson, of St. Thomas, Ont., has applied to the Board of Water Commissioners for leave of absence in order that he may attend the school of military instruction at London, Ont.

W. J. Shaughnessy has been appointed a director of Canada Foundries and Forgings, Ltd., to fill the vacancy caused by the death of Robert Bowie, Brockville. Not long since Mr. Shaughnessy was appointed to the board of the West Kootenay Power and Light Company. He is one of the well-known of the younger members of the Montreal Bar and a son of Sir Thomas Shaughnessy.

Sir Frederick Donaldson, head of the Woolwich Arsenal, who came to Canada last month with Lionel Hichens to inquire into the possibilities of ordnance manufacturing in Canada, has left for England. He will report to the War Office as to the conditions in Canada and the feasibility of establishing ordnance works in Canada which might be in a position to turn out big guns in time for use during the present war. It is understood that several of the big Canadian iron and steel firms are willing to go into the business, providing that sufficient orders are guaranteed to warrant the outlay for new machinery, and providing also that skilled workmen can be secured.

Trade Gossip

The Roelofson Elevator Co., Galt, Ont., have been awarded the contract for an elevator for the Susman & Cohen Co.'s new factory at Kingston, Ont.

The Collingwood Shipbuilding Co., Collingwood, Ont., has been awarded a contract for a large steel freighter, similar in size to the J. G. Hagarty.

The Consolidated Mining & Smelting Co., Trail, B.C., have awarded a contract for the supply of several electric travelling cranes to the Northern Crane Works, Walkerville, Ont.

The Villeneuve Machine Gun Co., a corporate firm, with a capital of $99,000, has just been granted its letters patent for the manufacture and production of machine guns, cannon and firearms of all denominations. The company was incorporated at Quebec.

The Orillia Molybdenum Co., Orillia, Ont., has made its first shipment of two tons of concentrates of Molybdenite to the British War Office. This is the first time that this ore has been treated in Canada. The company has received instructions from the War Office to make weekly shipments for an indefinite period.

Heavy Guns Likely to Be Made Here.—According to an Ottawa despatch, Montreal may shortly have an extensive industry in the manufacture of heavy guns and ordnance. J. H. Whitfield and M. J. Butler, of the Armstrong-Whitworth Corporation, whose extensive works are located on the South Shore, are now in Ottawa, and it is understood that the company is prepared to go into the manufacture of heavy guns and ordnance if orders are forthcoming.

Quebec Bridge Progressing.—The last connecting link in the north cantilever arm of the new Quebec Bridge was driven on Nov. 4, and the arm is now completed; in fact, the whole north side of the bridge is completed with the exception of a few bolts. The anchor arm of the south shore will be completed next week. The cantilever arm of the south shore will be completed next spring or summer, and the centre and final span will then be towed up and placed in position by next fall, it is anticipated, so that trains may be crossing the bridge before next winter.

Tenders

Toronto, Ont.—Tenders for lead covered cable, addressed to the chairman of the Toronto Electric Commissioners, will be received until Tuesday, November 16, 1915. Specifications and form of tender can be obtained at the office of the purchasing agent, 15 Wilton Avenue.

Toronto, Ont.—The Toronto Electric Commissioners will be glad to receive tenders for overhead line construction work. Particulars may be obtained on application to the Purchasing or Engineering Departments, 15 Wilton Ave.

Ottawa, Ont.—Tenders will be received up to Tuesday, November the 23rd, for the undermentioned items for delivery to H.M.C. Dockyards at Halifax, N.S., and Esquimalt, B.C.: Steel and iron bolts, nuts and rivets, electric cable and wire, mineral grease, castile soap, hard soap, turpentine, chemicals, cleansing powder, bunting. Forms of tender and all information may be obtained by application to the Naval Store officer at H.M.C. Dockyards at Halifax, N.S., or Esquimalt, B.C., or to G. J. Desbarats, Deputy Minister of the Naval Service, Ottawa.

Municipal

Mimico, Ont.—A site comprising 7 acres has been purchased for the proposed sewage disposal plant.

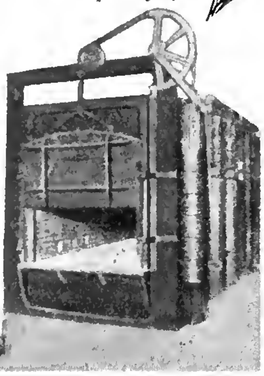
Niagara Falls, Ont.—A test by-law on the question of establishing a municipal bakery was lost by a vote of two to one, on Nov. 3.

Toronto, Ont.—Plans have been approved by the Board of Control for the proposed incinerator building on the river Don. The structure will cost $150,000.

Tilbury, Ont.—The request of the Brantford Gas Co. to be allowed to lay three gas mains to supply the manufacturers with Tilbury unpurified gas has been granted by the city council.

Edmonton, Alta.—An agreement has been drawn up between the city and the Edmonton Power Co. whereby the latter guarantee to spend $7,500,000 in five years in and about the city to carry out the terms of the contract.

Halifax, N.S.—The Board of Control have adopted the following report of Controller Harris, on the application of the Imperial Oil Co., for property at Africville, and recommend that the city council pass it. The company will probable spend $250,000 on buildings and plant.



TORONTO MARKETS

(Continued from page 459.)

for scrap copper, brass, zinc, and lead is reasonably active. The United States market is said to be over-supplied and a reaction may be expected. Quotations on the above-mentioned metals are unchanged with the exception of zinc, which has advanced, and is quoted at 10c per pound.

Metals

The general situation in the metal market is much the same as last week. The upward movement in tin continues and lead has also advanced slightly. There is no change in the copper market, but the position of this metal is a good one, and higher prices are more likely than otherwise. The spelter market is much firmer and indications point to higher prices in the near future. There is nothing of particular importance to note with regard to antimony and aluminum, except that supplies of the last-named metal are practically unobtainable. Solders are firmer and higher prices may develop shortly.

Tin.—Considerable activity has developed in the tin market and the upward movement continues. The market is in a sound position, but there is a possibility of a revival in speculation. Tin has advanced 1c and is quoted at 40c per pound.

Copper.—The market is steady and firm. Production is going on at a rapid rate, but at the same time consumption exceeds the output. The position of this metal is a strong one, as consumption will increase rather than decrease. Local quotations are firm at 19½c per pound.

Spelter.—The market is firm with a higher tendency. There is an improvement in demand in New York, both domestic and export. Spelter has advanced ½c, and is quoted locally at 18c per pound.

Lead.—The New York market is firm at the "Trust" price which is 5c per pound, while the London market has also advanced. The advance is attributed to increased demand. Lead has advanced ¼c and is now quoted at 6½c per pound.

Antimony.—The market is fairly active, but the general situation is unchanged. Antimony is quoted locally at 35c per pound.

Aluminum. — The situation is unchanged and supplies locally are almost unobtainable. Quotations are nominal at 60c per pound.

IT IS NOT the stockholders, the president or the claim agent who is getting hurt. It is the man on the job. For that reason, progressive companies are nowadays equipped with safety plans, safety devices and a safety organization.

If what you want is not advertised in this issue consult the Buyers' Directory at the back.

velopment of terminal facilities on the former Songhees Indian Reserve. It is hoped before the close of the year to have a section of the West Coast line completed as far as the first point reached at tidewater.

St. Marys, Ont.—An important hydro-radial railway meeting was held here on November 11. Mr. Lyon, chairman of the Ontario Hydro-Radial Union, presided. Secretary T. I. Hannigan was also present along with Engineer Gaby, chief engineer of the Ontario Hydro-Electric Commission, and about 35 representatives of the following municipalities: London, Lucan, Exeter, Biddulph, Blanshard and St. Marys. Resolutions were passed approving of the map plans as presented.

Toronto, Ont.—Plans for the second link in the Hydro-Electric Radial System that is to link up Toronto with Sarnia and take in all the municipalities along the line from Toronto, by way of Guelph and London, received emphatic approval on October 28 when the representatives of the eighteen municipalities interested in the section from Guelph to London met to consider the proposals of Sir Adam Beck and his colleagues of the Hydro-Electric Commission. By-laws will be prepared in the various municipalities and submitted to the ratepayers at the next municipal elections.

Trade Gossip

New Liskeard, Ont.—The Wabi Iron Works have recently installed an electric furnace.

The Linde Canadian Refrigeration Co. will install an ammonia rectifier and oil trap at the Municipal Abattoir, Toronto.

The National Steel Car Co., Hamilton, Ont., will manufacture motor-driven fire apparatus in addition to their present lines.

Gananoque, Ont.—The Ontario Steel Products Co. have received a large order for automobile springs and trench digging shovels.

Expansion of Hydro System.—Sir Adam Beck, Chairman of the Hydro-Electric Power Commission, had a meeting with the Ontario Cabinet recently and submitted further data with reference to increased power development at Niagara Falls.

The Standard Steel Co. has been organized in Montreal to manufacture steel products and shells. A building has been rented and will be equipped with the necessary machinery. The head office is in the Transportation Building, and the president is E. G. Jackson.

Petrolia, Ont.—The Western Sugar Refining Co., which proposes building a sugar beet refinery here, have appointed the following provisional directors: Ralph D. Mitchell and D. J. Kelly of Cleveland, O.; David A. Gordon of Wallaceburg, Ont.; K. C. Kerr and R. G. R. MacKenzie, of Petrolia.

Agricultural Machinery for France.—Two big trains made up of sixty carloads of agricultural machinery have been shipped by Massey-Harris Co., from Brantford, Ont., for use in France. War for some time cut off the export trade of the local branch of the firm, but lately it has picked up again.

The Nova Scotia Steel and Coal Co. has disposed of $1,500,000 of common stock and $1,000,000 of 6 per cent. debenture stock. The capital which has been obtained in this way will greatly strengthen the financial position of the company and enable it to comfortably take care of any additional business that is offering over and above the large amount which is now on hand.

The Canadian Briscoe Co. has been formed by Carriage Factories, Ltd., of Canada, as a subsidiary. The Canadian Briscoe Co. will assemble the parts in Canada from the Briscoe Motor Co., of Jackson, Mich., and the cars will be sold through Carriage Factories, Ltd., which has acquired the carriage manufacturing end of the McLaughlin Motor Co., Oshawa, Ont.

New Trade Commission.—The Minister of Trade and Commerce has appointed a new Trade Commission to the Far East. L. D. Wilgress, who for some time has been training in the department here, is going to Omsk, while C. W. Just will go to Petrograd. Mr. Just has conducted an extensive investigation into possibilities of trade with Russia and reports many promising openings.

Railway Earnings New High Record.—The gross earnings of the three Canadian railroads, the C. P. R., the G. T. R. and the C. N. R., for the month of October reached notable dimensions. For the fourth week they were $7,147,358, or an increase of $2,413,017, which is at the rate of 50.9 per cent. over the corresponding period a year ago. These are new high records for years. The combined gross earnings of the three roads for all October were $21,656,192, an increase of $4,942,000 over September, of $7,464,000 over August, of $8,500,000 over July, and of $8,790,000 over June. Compared with a year ago, the increase was $5,519,000, or 34.2 per cent., this being the first monthly increase since the war began, and comparing with a decrease of 3.7 per cent. in September.

The Canadian Steamship Lines, it is stated, have 107 boats in active service, 65 freight, of which 16 are on the ocean and 42 passenger. The ocean freighters, the same authority states, earn on the average $10,000 net per month, which for the winter months figures out at nearly $800,000. In addition to this, six vessels of the Quebec Steamship Company, a subsidiary, operate all year. The passenger revenue this year has not been as large as in 1914, but the above figures indicate that ocean traffic alone will wipe out last year's deficit. Freights from the head of the lake average about 4 cents this year against 1¾ in 1914. Operating costs have been cut down by means of various economies to the extent of about $400,000. These are the reasons why September and October earnings alone stood almost half a million dollars ahead of the corresponding months in 1914. It is well known that freight boats had very small storage cargoes at the head of the lakes last winter, but this year the capacity of the fleet of the company will be filled, to the extent of about 2,500,000 bushels, which, it is estimated, will net the company in the neighborhood of $200,000.

New Incorporations

The Ontario Aeroplane Co. has been incorporated at Toronto with a capital of $200,000 to manufacture aeroplanes, hydroplanes and water boats at Toronto. Incorporators: Jacob William Broudy and Thomas Hubert Wilson, of Toronto.

Gray-Dort Motors, Ltd., has been incorporated at Toronto, with a capital of $500,000 to make motor cars at Chatham, Ont. Incorporators: J. Dallas Dort of Flint, Mich., Robert Gray and William Murray Gray of Chatham, Ont.

The Algoma Nickel Mining Co. has been incorporated at Toronto with a capital of $10,000 to acquire and develop mines and mineral lands. Head office at Toronto. Incorporators: George Hugh Baird and Henry Nicol Baird, of Toronto.

The Maple Leaf Motors, Ltd., has been incorporated at Ottawa, with a capital of $750,000, to manufacture automobiles and motor cycles, etc., at Brantford, Ont. Incorporators—James Harley and Edmund Sweet, of Brantford, Ont.

The Reginal Construction Co. has been incorporated at Ottawa, with a capital of $100,000, to carry on business as contractors. Head office at Mont-

real, Que. Incorporators—Charles Gaspard Hebert and Arthur Laberge, of Montreal.

The Utilities Eqipment Co. has been incorporated at Toronto with a capital of $40,000 to manufacture electrical and mechanical apparatus and appliances at Toronto. Incorporators: William Davidson and John Calvin McFarlane, of Toronto, Ont.

The Dominion Magnesite Co. has been incorporated at Ottawa, with a capital of $100,000, to develop and operate mines, minerals, mining lands at Calumet, Que. Incorporators—Walter Robert Lorimer Shanks, Francis George Bush, of Montreal.

The Transcona Shell Co. has been incorporated at Ottawa, with a capital of $50,000, to manufacture shells, bombs and munitions of all kinds. Head office is at Montreal. Incorporators—F. G. Bush, G. H. Drennan and H. W. Jackson, all of Montreal.

Cleveland, Ltd., has been incorporated at Ottawa, with a capital of $40,000, to purchase a certain secret process known as the "Cleveland Process." Head office at St. John, N.B. Incorporators—Isaac MacDonald and Laurence Alexander Barry, of Halifax, N.S.

The E. W. Jeffres, Ltd., has been incorporated at Ottawa with a capital of $500,000 to carry on the business of manufacturing chemists at Walkerville, Ont. Incorporators: Edward Worsham Jeffres, of Detroit, Mich., and Albert J. Gordon, of Walkerville, Ont.

The Central Engineering Co. has been incorporated at Ottawa with a capital of $25,000 to carry on business as general dealers in and manufacturers of machinery at Montreal, Que. Incorporators: Thomas Arnold, Joseph Atter and Herbert M. Ewan, all of Montreal.

The Dominion Copper Products Co. has been incorporated at Ottawa, with a capital of $400,000, to manufacture articles made of copper, brass and all other metals, at Montreal. Incorporators—Walter Lorrimer Shanks and Francis George Bush, of Montreal.

The Canadian Dove-Smith Co. has been incorporated at Toronto with a capital of $40,000, to manufacture machinery and munitions of war at Toronto. Incorporators—Roderick George Kembly, Joseph Henry Harker, and Newton Howard Manning, all of Toronto, Ont.

Greenleafs, Ltd., has been incorporated at Toronto with a capital of $40,000, to purchase the business of Greenleaf & Son, machinists, electricians, automobile repairers, at Belleville, Ont.

ADVERTISING.

Advertising in a trade paper is simply stating openly who you are and what your business is. It is pointing out to the readers that you have something of service for them, a commodity of usefulness to profit both you and them. The only men who do not advertise are those who have nothing to offer. They are dead, even if they do not know it.

Incorporators—Henry Wilbur Greenleaf and Charles Orlando Greenleaf, of Belleville, Ont.

Yukon Copper Co. has been incorporated at Ottawa, with a capital of $200,000, to carry on the business of mining and smelting copper. Head office at Ottawa. Incorporators—W. D. Grenough, of Whitehorse, Y.T.; Alfred Thompson, of Dawson, Y.T., and J. F. Smellie, of Ottawa.

The Gunn Electric Co. has been incorporated at Ottawa, with a capital of $20,000, to manufacture electrical hydraulic, mechanical and other machinery at Montreal, Que. Incorporators—Edward James Gunn, William James Shaughnessy and Chilion Graves Heward, all of Montreal.

The Wizard Tire Inflator and Fire Extinguisher Co. has been incorporated at Ottawa, with a capital of $50,000, to manufacture tire inflators and fire extinguishers, fluid air, gas or other receptacles, at Toronto. Incorporators—John Edward Carroll, of Philadelphia, Pa., and James Douglas McWilliams, of Toronto, Ont.

TENDERS FOR SOUTH AFRICAN REFRIGERATING PLANT

THERE have been forwarded to the Department of Trade and Commerce, Ottawa, by W. J. Egan, Trade Commissioner, Cape Town, specifications and plans for the supply and erection of an ice-making and refrigerating plant and for the fitting up of refrigerating chambers at the municipal abattoirs, Newton, Johannesburg. The contract calls for the supply and erection at the above abattoirs of an ice-making and refrigerating plant with necessary foundations, etc., complete; all insulated walls, partitions, floors, ceilings, doors, etc., necessary to construct the various compartments in basement with all work required to leave same in complete working order; two lifts, with all operating gear, gates, etc., complete; all running rails for conveying, and hanging rails for hanging carcases, complete with all switches, hangers, runners, etc., in basement and lifts. Tenders for the above are to be in the tender box, municipal offices, Johannesburg, by or before noon on Thursday, December 30, 1915. Specifications and drawings may be inspected at the Department of Trade and Commerce, Ottawa. (Refer File No. A-1842.)

MONTREAL DRY DOCK & SHIP REPAIRING CO.

WHEN the steamer Rock Ferry went into dock at the end of Wellington Basin on Mill Street, Montreal, on November

6, to have her rudder repaired, she inaugurated a new era in the work to be done by the Montreal Dry Dock & Ship Repairing Co.

For nearly four years this concern has been doing work at the dock, which before that time was known as the Tate Dry Dock. All this summer work has been proceeding at deepening the dry dock so that its scope could be greatly extended. On Friday, November 5, a group of prominent business and shipping men were shown over the plant to see for themselves that now the dock can take any lake steamer which comes through the Lachine Canal.

The dock has been deepened four feet for 250 feet in length, and a new concrete bottom laid. The Rock Ferry is 260 feet long, and draws 11 feet when light, an indication of the capacity of the new dock. There is a good plant for iron work, completely supplied with air and electric tools. The dock is 50 feet wide and the blocks three feet six inches high. The entire length of the dock is 430 feet.

Among those present were—Thomas Hall, of the Hall Engineering Works, who is managing director of the Montreal Dry Dock & Ship Repairing Co.; F. H. Fox, secretary-treasurer; Captain Johnson, marine superintendent of the Canada Steamship Lines; E. Marceau, chief engineer Quebec Canals; D. O'Brien, superintendent Lachine Canal; Captain Archibald Reid, port warden; Captain J. N. Bales, assistant port warden; L. L. Henderson, manager and director Montreal Transportation Co.; F. W. Cowie, chief engineer Harbor Commission; A. Kastella, chief engineer Department of Public Works; George Hadrill, secretary, Montreal Board of Trade; Captain J. O. Grey, Frank Wright, and Ralph Hall, the last three from the Hall Engineering Works.

MUNITIONS EXPORTS FROM THE UNITED STATES

EXPORTS of war materials from the United States now average more than $1,000,000 a day, according to a statement issued yesterday by the Foreign Trade Department of the National City Bank. From the port of New York alone the exports in September included $6,500,000 worth of gunpowder, $3,500,000 worth of shells and explosive projectiles, $1,250,000 of cartridges, nearly $1,000,000 of dynamite, cordite and trinitrotoluol, $500,000 worth of primers and fuses, $1,000,000 worth of empty projectiles, and nearly $1,000,000 worth of firearms.

In addition there were shipped in September $1,000,000 of military goods, nearly $1,000,000 of aeroplanes and more than $6,000,000 worth of auto trucks. There also were enormous shipments of copper, lead, spelter, hospital goods, harness and saddlery. Most of the shipments were to Great Britain, France and Russia.

Catalogues

Don't Waste Your Fuel is the title of a folder issued by the James Morrison Brass Mfg. Co., Toronto. The folder describes and illustrates two patterns of

If what you want is not advertised in this issue consult the Buyers' Directory at the back.

recording gauges for steam pressure, vacuum and temperature ranges.

Temperature Booster.—The W. E. Clark Co., Toronto, have issued a folder describing the Clark temperature booster. This is a device for increasing the circulation of the water in hot water heating systems. A full description covering the construction and method of operation is given, accompanied by sectional views.

Shop Furnaces made by the American Shop Equipment Co., Chicago, Ill., are the subject of a supplementary bulletin recently issued. The lines briefly described include portable and stationary rivet forges, welding and forge furnaces, annealing, tempering and hardening furnaces, etc. The bulletin contains complete export shipping data for each product listed.

Heat Generator.—A booklet describing the "Knickerbocker" heat generator made by the James Morrison Brass Mfg. Co., Toronto. This appliance, which is designed for hot water heating systems, is illustrated and described, the illustrations including a number of diagrams of heating systems showing location of the generator. The method of installing the generator is described and also the benefits to be derived from its use.

Piston Rings—"To Save and to Hold Power"—is the title of a bulletin issued by W. H. Banfield & Sons, Toronto, Ont., and describing the "Leak-Proof" piston ring. The bulletin first of all deals with piston rings in a general way and then proceeds to describe in detail the principal features of "Leak Proof" ring. The method of making these rings is described, followed by instructions for installing and the variety of uses.

The Lighting of Textile Mills with Edison Mazda lamps is the title of bulletin No. 4906 distributed by the Canadian General Electric Co., Toronto. The bulletin contains a number of excellent half-tones showing interior views of textile mills where "Mazda" lamps are installed. The reading matter deals with "Mazda" lamps as applied to the illumination of textile mills, while a variety of types of lamp are illustrated. Tables are included giving data covering these lamps.

Book Review

Forging of Iron and Steel, by William Allyn Richards, B.S. in M.E., 219 pages 8 in. x 5 in., 337 illustrations. Published by the D. Van Nostrand Co., New York. Price $1.50 net. This is a new text book for the use of students in colleges, sec-

Steel Market

Owing to the fact that American mills have withdrawn prices on a number of steel products from this market, and that they are not for the present soliciting business in Canada, prices on Pittsburgh bars, plates and shapes will not be given in the selected market quotations until further notice. Steel companies in the States are unable to accept new business from this market as their output is booked up for several months ahead and furthermore prices are so variable that a firm quotation cannot be listed with any degree of accuracy.

Canadian mills have advanced prices on steel bars 25 cents, and are quoting $2.75 per 100 pounds, Toronto. Quotations on iron bars are unchanged at $2.50 per 100 pounds. Prices on steel bars are subject to change without notice and quotations are made only for immediate acceptance. The market is very strong and active and every indication points to still higher levels. The demand for steel for shells continues to increase and the capacity of the mills will be taxed to the limit to take care of the tonnage that will be required for the new orders for munitions. The steel industry is passing through a phenomenal period of prosperity which will benefit the trade to a degree never anticipated as recently as twelve months ago. No other price changes except the ones noted above have been made this week, but boiler tubes and boiler plates will no doubt advance in the near future. Bolts, nuts and wrought iron pipe are very firm and higher prices are anticipated.

Prices of galvanized sheets are firm and are expected to advance. The market is unsettled and it is said that some makers have practically withdrawn from the market. The scarcity of steel is affecting the sheet makers, acid is scarce and high, while the abnormal price of spelter is also an important factor in the situation.

In the United States the market is very strong and prices on steel products continue to advance. Steel companies are extending their plants and are operating at capacity. Many mills have their output sold for four and five months ahead, and some for the first half of next year. There is a very heavy demand for steel bars for munitions and prices are going higher. Steel bars, plates and shapes are now being quoted at 1.70c Pittsburgh. Bessemer and forging billets are higher and are being quoted at $27 and $48 per ton Pittsburgh, respectively. Wire rods have advanced, and are now quoted at $37 f.o.b. Pittsburgh. Black sheets are higher at $2.25 Pittsburgh.

Pig Iron

The market is strong and prices of domestic and American pig iron are higher. Hamilton and Victoria brands have advanced 75c and are now quoted at $21.75 per ton, Toronto. Grey forge has advanced to $15.95 Pittsburgh, while Lake Superior charcoal is now quoted at $17.25 f.o.b. Chicago. The pig iron market is becoming more active in sympathy with that of steel. There is a heavy demand for steel making grades. Canadian consumers are buying heavily in the States, but cannot get all the tonnage they require.

Old Materials

The market is firm with improved demand for copper scrap and heavy melting steel. Prices are considerably firmer, and zinc has advanced 1c, being now quoted at 12c per pound. No.1 wrought iron and No. 1 machinery cast iron are both stronger and higher. All grades of grass are in good demand and prices are firm.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Messrs. S. Ruperti and Alexsieff, care Military Atache, Russian Embassy, Washington, D.C.

Machine Tools

The situation in the machine tool market is much the same as last week. Dealers are very busy figuring on tools for the large shells and have sold a number of lathes for machining the 6-in. type. A large number of lathes, 24-in. to 30-in. swing, will be required for the large shells, and it is understood that a considerable amount of business is ready to be placed by the various firms who are preparing to undertake their manufacture. Prices of lathes and other tools have advanced considerably, but deliveries on the large size lathes are not as backward as on the smaller tools. Second-hand tools suitable for shell work have risen in price, and are not so easy to obtain as formerly, the market having become depleted.

Supplies

The market continues active and prices are firm. There are no price changes of importance to note this week but there is an upward tendency in some lines. Linseed oil is expected to advance again. Waste is firm and in good demand. Higher prices are anticipated for red lead, and lead wool may also advance.

Metals

The market is steady and there are no price changes to note with the single exception of spelter which has advanced again. The tin market which advanced sharply last week on a report that the Suez Canal was closed is now weak as a result of this rumor having been proved incorrest. Copper is higher in London, but unchanged here. The advance in spelter is due to a scarcity of this metal and an apparent attempt to excite the market. The lead market is firm but unchanged. Considerable strength has developed in the antimony market and prices are very firm. The scarcity of aluminum continues and prices are nominal.

Tin.—The strong market which developed last week has not been maintained and the market is now dull and weak. The Suez Canal scare had apparently no foundation in fact, consequently the market fell off, but recovered later. There is a scarcity of spot tin and should business improve the price might advance. Local quotations are unchanged at 48c per pound.

Copper.—The market is strong and higher in London. There has been some heavy buying recently, and it is thought that the market will go higher before the movement stops. Local quotations are firm and unchanged at 20c per pound.

Spelter.—The marke is unsettled and quotations nominal. A scarcity of spelter in London has resulted in a further advance in prices for prompt and end of November requirements; futures, however, are selling at a discount. Spelter has advanced 2c and quotations are nominal at 20c per pound.

Lead.—The market is quiet but firm. The "Trust" price is being well held at $5.25, New York, and it is probable that it may advance. Local quotations are unchanged at 7c per pound.

Antimony.—The market is very strong with an upward tendency. There is a scarcity of spot antimony and a large business is being done in futures. In the London market, the price of antimony is controlled by the British Government which helps to steady the market. Local quotations are firm and unchanged at 40c per pound.

Aluminum. — The situation is unchanged and supplies are still very difficult to obtain. Quotations are unchanged at 65c per pound.

Advertisers Cannot Be Overlooked

Being in the background of a manufacturer's mind at a moment which decides the direction business shall take, may mean serious losses. When you advertise you cannot be overlooked—you always receive consideration—a consideration above that accorded the house that does not see the benefit of talking to the manufacturer when he has the time to listen — when he sits down to read *Canadian Machinery*.

GRAIN EXPORTS REDUCED

WITH little prospect of improved conditions in the month of November, reports of this year's grain exports through the port of Montreal up to the end of October show a distinct falling off as compared with the corresponding period last year, while a large increase of grain shipped from many of the Atlantic ports of the United States is recorded.

The total amount of grain exported from Montreal to October 31 of the current year is 34,664,528 bushels, according to reports compiled by the Board of Trade, as compared with 58,112,000 bushels for the corresponding period of 1914, a decrease of 23,447,472 bushels. The total for this year is made up of 27,807,108 bushels wheat, and 5,886,000 bushels oats, the remainder being corn and barley.

Total exports of grain from St. John, N.B., for the same period, show a smaller diminution as compared with last year, the figures, as compiled by the Consolidated News Statistics and Transportation Bureau, of Philadelphia, being 5,174,000 bushels for 1915, and 5,556,000 bushels for 1914.

OCTOBER EXPORTS NEARLY DOUBLED

THE feature of the monthly statement of Canada's trade, issued on November 19, by the Hon. J. D. Reid, Minister of Customs, is the very substantial increase in the volume of exports. For the month of October last, Canada exported eighty million dollars worth of goods, or nearly double the exports for the corresponding month of 1914.

There are increases all along the line, the chief being agriculture, $39,833,000, compared with $17,900,000 for October, 1914; animals and their product, October, 1915, $12,000,000; October, 1914, $8,000,000; manufactured goods, October, 1915, $12,800,000; October, 1914, $7,100,000; minerals, $6,600,000, compared with $5,104,000, while there is a substantial increase in the export of fisheries and lumber.

The exports for October doubled the imports for the same period, the imports being $39,000,000, made up of $22,800,000 dutiable goods, and $16,700,000 free goods.

The total Canadian trade for October, 1915, was $150,000,000, compared with $139,000,000 for the corresponding month last year. The statement shows that the Canadian trade for the seven months ended October last was $709,000,000, compared with $640,000,000 for the corresponding seven months of 1914. For the seven months ended October last, the exports of agricultural products reached $100,000,000, compared with $75,000,000 for the corresponding period of 1914. For the seven months of the present fiscal year the exports were largely in excess of the imports, the latter being $253,000,000, and the domestic exports $336,000,000.

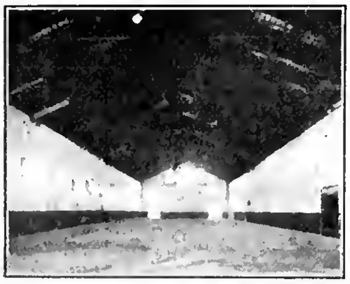
JOHNS-MANVILLE SERVICE COVERS THE CONTINENT

JOHNS-MANVILLE SERVICE

JOHNS-MANVILLE SERVICE COVERS THE CONTINENT

IN every important city of North America the Johns-Manville purchaser finds Johns-Manville Service. It exists for his benefit and in order that every J-M Product sold him may render continuous satisfaction.

Actual service has proved that J-M Fire-proof Cold Water Paint reduces lighting bills at least 25%



Before using J-M Cold Water Paint

After using J-M Cold Water Paint

It brightens up corners and dark places, thereby making daylight last longer and necessitating the use of fewer lights when working at night.

And in addition to this great saving, the productiveness of employees is increased from 10 to 40%, according to local conditions.

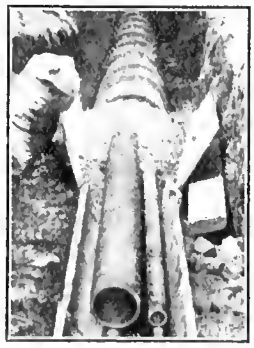
J-M Cold Water Paint is composed of various minerals and cementing compounds and is mixed with ordinary water, which costs you practically nothing. Due to this economy, this paint costs only a fraction as much as oil paints. It covers a greater area and one layer covers better than two layers of oil paint.

Contains no oil, alkali, lime or injurious chemicals, so won't discolor with age nor harm hands or clothing. Being absolutely fireproof it is approved by the Fire Underwriters, therefore insurance premiums are often reduced where it is used.

J-M Fireproof Cold Water Paint, when applied according to simple directions, forms a hard, firm, sanitary and odorless coating which will not chalk, scale, peel or rub off.

The method to be used to carry steam underground is no longer a matter of experiment

Because facts point to the J-M Sectional Conduit System as being most efficient and economical. There are several considerations that must be given due thought in every underground steam line. (1) Efficiency—the ratio of the steam you send through the line to that which is received at the other end. (2) Cost—meaning total cost: that is, first cost, repairs, inspection and maintenance. (3) Durability—How long it will last, or "how soon must this system be renewed." (4) Depreciation—which means the money you must earn, and save, to pay for the renewal of the installation when the present one is gone.



J-M SECTIONAL CONDUIT

is the logical choice under all these considerations.
Efficiency—90% and up. Cost—lowest yet. Life—endless. Depreciation—negligible.
Tests that prove this are yours for the asking. Tell us where to send them.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Vancouver, B.C.—The Shell Company will build an oil refinery on Burrard Inlet.

Seaforth, Ont.—The Robert Bell Engine Co. have been awarded a contract for shells.

Hamilton, Ont.—The Acme Stamping Tool Works will make an extension to their plant to cost $3,000.

Vancouver, B.C.—The molding shops of the Vancouver Engineering Works, were damaged in a recent fire.

Leamington, Ont.—The town council will purchase two 110 h.p. return-tube boilers for the pumping station.

Montreal, Que.—The Castings Co. of Canada, which was recently incorporated, will build a foundry at Valleyfield, near here.

Fort William, Ont.—The Fort William Coal Docks Company will build an extensive addition to its plant on Mission River, to cost $200,000.

Petrolia, Ont.—A beet sugar refinery will probably be built by the Marine City Sugar Co. The cost of buildings and plant is estimated at $800,000.

Collingwood, Ont.—It is reported that the Imperial Steel & Wire Co. have received an order for shells in addition to the order for war material recently announced.

Orillia, Ont.—The J. R. Eaton & Sons have received a contract for 25,000 six-inch shells. The company have for some time been working on a large order for ammunition boxes.

Galt, Ont.—Owing to trouble at the pumping station, the Waterworks Commission have practically decided to purchase another electric motor to drive one of the turbine pumps.

Welland, Ont.—The Electric Steel & Metals Co. are building a new machine shop 300 ft. long by 50 ft. wide, and an office building 50 ft. by 40 ft. An electric furnace is also being installed for turning out shell blanks.

Montreal, P. Q.—The Standard Steel Co., which has recently been incorporated, has taken over an existing foundry on Atlantic avenue. The plant will be equipped and operated as a steel foundry. An extension to the plant is contemplated.

London, Ont.—Plans for an addition to the Ford factory on Waterloo Street are being prepared, although no construction work will be started this year. The company has purchased a site, 180 by 232 feet, in the rear of its present building, on which the new structure will be erected.

Dawson, Y. T.—The steam generating plant of the Canadian-Klondike Mining Co. was completely destroyed by fire Oct. 30. The plant was used for driving dredges, heating the company's shops, etc. The machinery burned included three large water-tube boilers and a 400 k.w. steam turbine. The plant is to be rebuilt on a larger scale.

Welland, Ont.—The Canada Forge Co. will build an extension to their plant. The new building will have a ground area of 180 x 80 feet, and will be of structural steel. The cost is estimated at $20,000, and the equipment to be installed will cost $100,000. The building will be used for four additional hydraulic presses for making six-inch high-explosive shells. T. J. Dillon is manager.

Vancouver, B.C.—The recently organized Port Moody Steel Works, Ltd., are now busy clearing their site at Port Moody and anticipate within a short time starting construction work on their buildings, being far enough advanced early in the new year to start operations. The company has a 100-acre site at Port Moody and the council of that place have guaranteed bonds to the extent of $100,000.

Electrical

Granton, Ont.—A Hydro-Electric system will be installed here at a cost of $5,000.

Forest, Ont.—The Town Council contemplate installing a Hydro-Electric system.

Verdun, Que.—Council is considering the extension of the electric lighting system.

Granton, Ont.—The Township of Biddulph purpose spending $3,500 on a Hydro-Electric distribution system. A by-law will be voted on .

Petrolia, Ont.—Construction work on the hydro system has been suspended because the Commission's recommendations have not been carried out.

Orangeville, Ont.—The county has passed a by-law guaranteeing the bonds of the corporation of the Town of Orangeville to the amount of $33,000, repayable in 20 years, for the purchase of the plant of the Pine River Light and Power Co., and to provide for the cost of a plant to distribute electric power to be supplied by the Hydro-Electric Power Commission of Ontario.

Eugenia Falls Plant.—The new power plant at Eugenia Falls owned by the Ontario Hydro-Electric Commission was formerly opened by Sir Adam Beck on November 18th. The plant will serve a large section of the Georgian Bay district with electrical energy. The present capacity of the plant is 4,000 h.p., but 8,000 h.p. can be developed. The total head of water available is 450 feet. The plant represents a capital investment of $600,000 and transmission lines and transformer stations $500,000 more. Should the circumstances warrant, the Eugenia Falls plant can be linked up with the other two plants on the Severn, namely, Big Chute and Wasdall's Falls.

Municipal

London, Ont. — The contemplated waterworks extensions include a pumping installation.

Dryden, Ont.—The Town Council are considering the question of installing a waterworks system.

Port Dover, Ont.—The town council contemplate making extensions to the waterworks system.

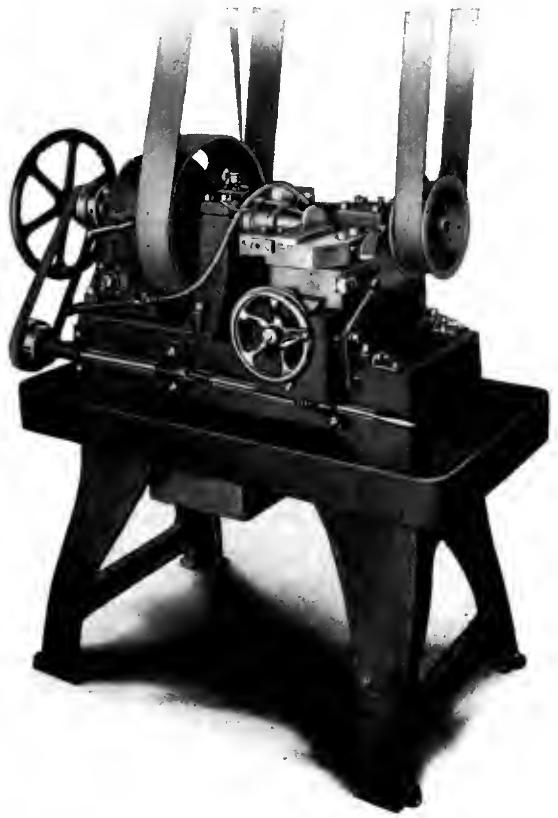
Southampton, Ont.—The installation of a hydro-electric system is under consideration by the town council.

West Lorne, Ont.—A by-law will be prepared to submit to the ratepayers to borrow $8,000 for a hydro-electric system.

Owen Sound, Ont.—A by-law will be voted on by the ratepayers to authorize a loan of $12,000 to the Owen Sound Shoe Mfg. Co.

Peterborough, Ont.—A by-lay is being prepared covering a loan of $3,500 to J. C. Ellis, who proposes building a mattress and bed-spring factory.

THE BANFIELD PLUG MILLER



For Turning, Facing and Milling the Thread on Gas Check Plugs for High Explosive Shells.

THIS machine is especially designed for finishing base plugs, turning the outside diameter, finishing the face with any camber desired, and milling the thread, all in one chucking, the complete plug being finished in three minutes by unskilled labor.

The machine is equipped with quick draw in collet. Drive pulley 16" x 4", with bronze bush having cut jaw clutch for turning and facing. Bronze worm gear 74 to 1 ratio, with cut jaw clutch for milling, driven by 10" x 1½" flanged pulley. The milling cutter is driven by an 8" x 2½" flanged pulley. Tool post carriage is equipped with power feed (two speeds) having automatic stop. Power feed pump with relief valve driven from worm shaft (*all drives direct from main line shaft*). Rigidly built, simple and economical to operate.

Overhead Runways and Trolleys, Cranes, Derricks, Chain Blocks, Electric Hoists and Trolleys, Rope Blocks, Friction Hoists, Hydraulic and Hand Power Ash Hoists, Coal Handling Machines, Gravity Roller and Spiral Conveyors.

We Are Installing

BEATH OVERHEAD TRACKS, TROLLEYS AND HOISTS

For Hoisting and Conveying

5-in., 6-in., 8-in. and 9.2-in. Shells

in the receiving, forging, machinery and shipping departments. Beath Overhead Runways require no floor space and are particularly adapted for this service.

The weight of these Shells have caused a new problem in handling that will have to be met and overcome by manufacturers of these heavier types of explosives

Let our engineering department show you how a Beath Overhead Runway can be made to fit into your requirements.

W. D. Beath & Son, Limited

ENGINEERS AND MANUFACTURERS

20 Cooper Avenue - TORONTO

If what you want is not advertised in this issue consult the Buyers' Directory at the back.

Brockville, Ont. The ratepayers have voted in favor of granting exemption of taxes to the Newell Manufacturing Co., who propose establishing a branch factory here.

St. Marys, Ont.—There is a prospect of St. Marys getting a new industry. A Michigan concern has written to council asking what terms the town could offer should it locate here.

Edmonton, Alta.—The City Council has decided to submit a by-law on December 13 authorizing an expenditure of $275,000 on the construction of a sewage disposal plant.

Regina, Sask. -The city will install a new pumping unit at its waterworks plant to be driven by electricity, and have a capacity of 2,500,000 gal. per day and to cost $12,000. George Beach is the clerk.

Orillia, Ont.—The by-law for raising $50,000 for the purpose of rebuilding the town hall according to the plans prepared by Messrs. Burke, Horwood & White, was decisively defeated by the ratepayers on Nov. 17.

Port Dover, Ont.—Port Dover may shortly install a waterworks system. The town has two alternatives. Water can be brought by gravitation from Doan's Springs, which are two miles from the town. The other way is to take the water out of Lake Erie. It is proposed, if the latter plan is chosen, to build an intake pipe of 1,200 feet, and then have mechanical filters, which would be established near The Globe Park. E. A. James, of Toronto, is the engineer.

Brockville, Ont.—Seven tenders have been received by the Water and Light Commission for the proposed filter plant. The following alternative proposals are being considered: Barber & Grant, Toronto, A. $34,000; B, $94,500. New York Continental Jewel Co., A. $35,000; B. $87,128. Pittsburgh Filter Co., A, $42,-916; B. $97,746. Roberts Filter Co., Darby, Pa., A. $39,000; B. $95,193; C, equipment only, $36,500. Norwood Filter Co., Cowansville, Que., A. $40,800; B, $94,057.

General Industrial

St. Anns, N.S.—The Cape Breton Pulp Co. will rebuild their plant which was recently destroyed by fire.

Halifax, N.S.—The Brandram-Henderson Co., paint and white lead manufacturers, will build a new factory.

Fort Erie, Ont.—The International Safe Co. will build an extension to their factory. S. A. Waugh is president.

Parry Sound, Ont.—An explosion at Nobel last Monday wrecked a section of the plant of the Canadian Explosives, Ltd.

Kingston, Ont.—The Separate School Board are considering the question of installing fire escapes on the school building here.

Ingersoll, Ont.—The Waterhouse Knitting Mills will be extended, the factory remodeled and new machinery installed. Thomas Waterhouse is the president.

Haileybury, Ont.—It is understood that the purchase from C. A. Foster of his sawmill here by the Riordon Paper Mills of Montreal, will be followed by the building of a large pulp and paper mill.

Tenders

Grand'Mere, Que.—Tenders are being received for the supply of one 500 h.p. turbine and dynamo. Engineer, L. S. Pariseau, Montreal.

St. Hyacinthe, Que.—Tenders will be received up to December 14, for a mechanical filter plant. Plans and specifications may be obtained at the office of Hector Cadieux, city engineer.

Toronto, Ont.—Tenders will be received until Tuesday, Nov. 23, 1915, for

automatic roller fire doors at new Central Technical School. Specifications may be seen and all information obtained at the office of the Superintendent of Buildings, City Hall.

Toronto, Ont.—Tenders will be received by the Board of Education until Friday, Nov. 26, 1915, for ventilating fans, iron fence, ash hoist, local telephones, bronze tablets, steam fittings, etc. Specifications may be seen and all information obtained at the office of the Superintendent of Buildings, City Hall.

Halifax, N.S.—Tenders will be received by the Governor of the Province of Macao, up till January 8, 1916, for the supply of a steel, self-propelling dredge for the use of the Macao Harbor Works. Full particulars may be obtained at the office of Fred. H. Oxley, Consul for Portugal, Keith Bldg., Halifax, N.S.

Toronto, Ont.—Tenders will be received by the Chairman, Board of Control, City Hall, up to Tuesday, December 7, 1915, for the supply and erection of a mechanical mixing apparatus for the high-level chlorination plant, Wilton avenue and Don River; also the supply and erection of a mechanical mixing apparatus for the low-level chlorination plant, Eastern avenue and Don River. Specifications and forms of tender may be obtained at the Works Department, Room 6, City Hall.

Building Notes

Sarnia, Ont.—A new public school building will be built at an estimated cost of $50,000.

Montreal, Que.—The D. H. Hogg Co. will build a factory to cost $5,000. A building permit has been obtained.

Montreal, Que.—A building permit has been issued to the City Ice Co., who propose building a plant at a cost of $2,500.

Toronto, Ont.—The foundations have been completed for the new offices for the Board of Education. The building will cost $100,000.

Vancouver, B.C.—A Union Station for the Great Northern and Northern Pacific Railways will be built on a site purchased on False Creek. Fred. L. Townley, of Vancouver, is the architect.

Toronto, Ont.—The Board of Education have obtained a permit to erect the new Park School, costing $186,000. The plans call for the erection of a three-storey brick building at 126 Sydenham street.

Contracts Awarded

Toronto, Ont.—The contract for building the new incinerator has been awarded to E. H. Thomas of this city at $84,500.

Hespeler, Ont.—Grill Bros. have been awarded the contract for the waterworks pumping station and will start work at once.

Woodstock, Ont.—The contract for the new steel bridge over Thames street has been awarded to the Hamilton Bridge Co., Hamilton, Ont., for $3,190.

Berlin, Ont. — The Canadian Allis-Chalmers, Ltd., Toronto, have been awarded the contract for the pumps for the new sewage disposal plant. The amount of the tender was $4,492.

Personal

Col. Frederic Nicholls, president of the Dominion Steel Corporation, has arrived in London on a visit to the Old Country.

Colin C. Campbell, senior member of the firm of R. Campbell & Sons, pottery manufacturers of Hamilton, Ont., died on Nov. 15, aged 53 years.

Alfred W. Smithers, chairman of the English Board of the Grand Trunk Pacific Railway, who has been spending several weeks in Ottawa and Montreal, sails this week for England.

Trade Gossip

The Munitions Committee has ruled that the price of steel for ammunition to be made in Canada shall not exceed 3½ cents a pound.

The Canada Cement Co., Montreal, which recently received a large order for the manufacture of shells, will install an electric furnace for the purpose of making the steel required.

Cobourg, Ont.—The machinery in the old Provincial Steel Co.'s plant here has been purchased by the A. R. Williams Machinery Co., of Toronto, and will be shipped to Victoria, B.C.

Calgary, Alta. — The Calgary Iron Works has received an order for an additional 5,000 shells. The Buckeye Machinery Co. is about to get another contract. The latter company may get an order for 50,000 shells.

South Porcupine, Ont.—By changing the gold extraction system from the old amalgamation process to cyanide it is expected a greater recovery will be made

at the Dome Lake mill. The cyanide equipment is now being added.

Amherst, N.S.—The buildings, plant and machinery of the Hewson Pure Wool Textiles Co. was sold on Nov. 17 to E. F. Stevens of Halifax, N.S., representing the bond holders, for $102,000. The concern will be reorganized.

The Pine River Light and Power Co. power house, transmission lines, etc., within the corporation limits of Shelburne, N.S., will pass into the possession of the town December 1, the necessary deal having been closed last week. The town will pay $4,360 for the outfit.

Gold Medal for G. T. R.—The Grand Trunk system has been awarded the gold medal (highest award) and diploma for its exhibit at the Panama-Pacific International Exposition at San Francisco. The exhibit formed scenic, agricultural and industrial resources of Canada.

Vancouver, B.C.—Applications for all the forty acres of the False Creek foreshore which is being filled in under the direction of the Board of Harbor Commissioners, have been received, according to the members of the board. Among those who desire to lease sites are a number of local firms, but a number of outside companies desire to establish industries here.

Marshall-Weden Machine Gun.—William Marshall, consulting engineer of Toronto, one of the inventors of the Marshall-Weden machine gun, has sold to the St. Louis Car Co. the right to manufacture the gun in all countries of the world except Canada. It is stated that he will receive about $30,000,000 in commissions on a large order from the French and Russian governments.

Demand for Old Rails.—The inability of the mills of the Pittsburgh district to accept orders for steel rails for quick delivery has resulted in numerous enquiries from foreign governments for second-hand rails. It was learned last Friday that agents for Italy, Switzerland and the Belgian Congo are trying to place orders in Pittsburgh for 50,000 tons of old rails, to be used chiefly for repair work on Continental railroad lines.

Empire Reconstruction.—Lord Rosebery, speaking on Empire reconstruction, said that Imperial sentiment in Canada and Australia was at one time a pale shadow of what it is now. The blood which the Dominions have shed in our behalf must in consequence change the the Empire's constitution. He could not doubt that when the efforts of the Peace Congress were over there will appear a gigantic task of reorganization of the British Empire. "We should have to clean the whole of our slate before writing the new organization upon it," he said.

The Dominion Steel Corporation is devoting particular attention to the production of shell steel, which is in such active demand, and is leaving the turning out of shells to the other companies. The management went into the matter of shell output with the old shell committee, but did not see its way clear to take on the heavy capital outlay incident to taking on shell production as well. It is stated in steel circles that further foreign orders, particularly Russian, are now available, if the Canadian mills can give any guarantee of being able to make deliveries as required.

Dominion Industries Will Be Mobilized.—The Economic and Development Commission is receiving suggestions from leading organizations interested in agriculture, stock raising, fruit growing, marketing transportation, immigration and other matters affecting the progress of Canada. Questions requiring the consideration of technical experts will be dealt with by proper special committees of inquiry. It is the aim of the commission to proceed as rapidly as possible toward assisting in the mobilization of the agricultural and industrial resources so that Canada may be in the best possible position to meet after-war conditions.

Guelph, Ont.—Chief Engineer Gaby of the Hydro-Electric, with his staff, has been in the city recently in consultation with the City Council. The members of council went over the routes proposed by the Hydro engineers and others that had been suggested by the city engineer. The route favored by the city engineer would cost, Mr. Gaby stated, $150,000 more than the one drawn by the Hydro engineers in the first place. At the final meeting of council a resolution was put through favoring the original plans submitted by the Hydro engineers. This means that the original plans, on which Guelph's share was placed at $700,000, will be submitted to the ratepayers at the January elections.

Steel for U.S. Battleships.—Congress may be asked to place a temporary embargo on exports of structural steel to the European belligerents in order to afford a sufficient supply of the metal for use in the construction of the two battleships, bids for which were opened at the Navy Department last week. This plan is suggested as a result of the disclosure that neither of the new battleships can be laid down before next summer because of a lack of steel. The entire output of the American steel plants, it is said, has been taken by the warring nations. Secretary of the Navy Daniels, who is deeply concerned over the fact, hints that unless steel plants can be in-

duced to insure preference for Government orders Congress may be urged to act.

Imported Shell Forgings.—A duty of 32¼ per cent. is imposed on shell forgings entering Canada from the United States. Up to the present it has been deemed wise by the Canadian Government not to remove the tariff, as some twelve Canadian companies have been turning out forgings at a rate sufficient to supply the needs of other manufacturers who merely finish shells. Since the recent further distribution of shell orders by the Munitions Committee at Ottawa it is, however considered advisable in some quarters to have the duty removed, on the ground that the output of shells in Canada would be increased by the importation of forgings from the United States. It is announced from Ottawa that the Munitions Committee has fixed the price of steel for ammunition to be made in Canada. It must not exceed 3½c per pound.

After the war what? We cannot go back to the status quo ante. Class jealousy is breaking down in the trenches. Two million soldiers will come back appreciating the meaning of the phrase "an officer and a gentleman;" 50,000 officers one and all saying that the men are splendid. . . . I believe that it is good business to treat the workman well, to welcome him as a partner—a junior partner who is bound to take a more prominent share in the management and the profits of the concern in the near future. Good business or not, it is the clear duty of every employer to-day. We have had enough of the workman striking against the master in South Wales, of the master hailing the workman before munition tribunals on Tyne and Clyde, while the brothers of each are dying side by side in Flanders and Gallipoli.—Chairman of a Controlled Establishment.

The Willys-Overland, Ltd., has recently been incorporated with a capital of $6,000,000, and with head office in Toronto. The new company will take over the complete motor business of the Russel Motor Car Co., Ltd., and the complete Canadian business of the Willys-Overland Co. The intention is not merely to assemble, but to provide for the complete manufacture at the West Toronto plant of the Overland and Knight motor cars. John N. Willys, head of the Willys-Overland Co., of Toledo, will become president of the new company, and T. A. Russell, present vice-president of the Russell Motor Car Co., will be vice-president. Lloyd Harris will also be a member of the board, and there will be other Canadian directors. It is understood that under the new arrangement the Russell Motor Car Co. will continue

its bicycle and munition departments as heretofore, but its motor car interest will now be represented by its holdings in the new Willys-Overland, Ltd.

New Incorporations

The Hamilton Aero Mfg. Co. of Vancouver, B.C., has been incorporated with a capital of $50,000.

The Great Western Direct Power Engine Co., of Vancouver, B.C., has been incorporated with a capital of $25,000.

The Eclipse Iron Works, Ltd., Vancouver, B.C., has been incorporated with a capital stock of $20,000 to manufacture iron, steel, machinery, etc.

The International Gas Co. has been incorporated at Ottawa with a capital of $125,000. Incorporators: W. Bradley, T. A. Beament and A. H. Armstrong.

Atlantic Chemicals, Ltd., have been incorporated at Ottawa with a capital of $50,000 to manufacture chemicals and drugs at Toronto. Incorporators: Frank Regan, John G. Holmes, of Toronto, Ont.

The Castings Co. of Canada, Ltd., has been incorporated with a capital of $40,000. Head office at Montreal and works at Valleyfield, Que. Incorporators: H. Cohen, A. Ellison and S. G. Metcalfe, of Montreal.

The Canadian Lockers, Ltd., has been incorporated at Ottawa, with a capital of $100,000, to manufacture lockers, vaults, etc., at Toronto, Ont. Incorporators—H. Riley, J. W. Bicknell and J. S. Duggan, all of Toronto.

The Reliable Oil Co. has been incorporated at Ottawa with a capital of $40,000 to produce and refine oil and oil products at Montreal. Incorporators: Henry J. Trihey, Ernest Lafontaine and Michael T. Burke, all of Montreal.

Gres Falls Development Co. has been incorporated at Ottawa with a capital of $10,000 to purchase and develop water powers. Head office at Montreal. Incorporators: Gordon W. MacDougall and Lawrence McFarlane, of Montreal.

The Cheney Waterworks Co. has been incorporated at Toronto, with a capital of $1,500, to construct and operate a waterworks system at Cheney, Ont. Provisional directors—J. Limery, D. and A. Legault, of Cheney, Ont.

The Canadian Briscoe Motor Co., Ltd., has been incorporated at Ottawa with a capital of $200,000 to manufacture motor cars and trucks. Head office at Brockville, Ont. Incorporators: T. J. Storry, A. O. Heather and H. L. McDowell, all of Brockville, Ont.

The Canadian Crow Motor Co. has been incorporated at Toronto, with a capital of $100,000, to manufacture motor cars at Mount Brydges, Ont. Provisional directors are J. K. Kidd, Edward R. Bond and G. Lowthian.

The Brandon Shell Co. has been incorporated at Toronto, with a capital of $100,000, to manufacture munitions at Toronto, Ont. Incorporators—Harold W. Shapley, William B. Milliken, and Gordon McLaughlin, all of Toronto.

The Arena of London, Ltd., has been incorporated at Toronto, with a capital of $40,000, to operate an arena and manufacture ice at London, Ont. Provisional directors—W. I. Spettigue, F. B. Ashplant and E. B. Graham, all of London.

The Ideal Foundry & Hardware Co. has been incorporated at Toronto, with a capital of $50,000, to take over as a going concern the Imperial Foundry Co. of Toronto. Provisional directors—A. E. Furniss, R. M. Yeomans and B. MacDonald.

The Salt Development Co. of Canada, Ltd., has been incorporated at Ottawa with a capital of $35,000 to develop and manufacture salt and salt products. Head office at Montreal. Incorporators: Louis A. David, Louis E. A. Mailhiot and Segfried H. R. Bush, all of Montreal.

Catalogues

Sand Mixers.—The Sand Mixing Machine Co., New York, have issued a booklet containing reproductions of 30 advertisements from customers who have purchased their auto sand cutter. In addition to the above, the machine is fully described and illustrated.

"Lagonda" Valves.—The latest publication, N-3, issued by the Lagonda Mfg. Co., of Springfield, Ohio, is a 24-page bulletin on their triple-acting automatic cut-off valves and non-return valves. This book briefly, but completely, discusses the function of these valves, and illustrates the several types made by the Lagonda Mfg. Co., which are the standard angle type and straight way valve, the low squat body valve for low head room, and the horizontal valve. A copy of this bulletin will be sent to anyone on request.

IMMEDIATE DELIVERY

WE CALL ATTENTION TO THE FOLLOWING TOOLS, ALL OF WHICH ARE IN THOROUGHLY FIRST-CLASS CONDITION. READY FOR IMMEDIATE SERVICE. WITH NET PRICES ATTACHED.

SCREW MACHINES.

(8) Cleveland Automatic Screw Machines, with 3⅝" spindle capacity. These machines are of 1909 model. Price ($2500.00) each. F.O.B. shipping point.

TURRET LATHES.

One Jones & Lamson 2 x 24 flat turret with bar equipment, cone driven, condition first class. Price $750.00

One Garvin No. 3 turret lathe, 18" swing, with 2⅛" hole through spindle, back geared and friction head. Price $450.00

One Garvin No. 2½ turret lathe, 16" swing, 1½" hole through spindle, back geared and friction head. Price $400.00

One American Tool Works Co. turret lathe, 18" swing with 3" hole through spindle, equipped with back gear, friction head. Price.. $700.00

One Pratt & Whitney No. 3 turret lathe, 14" swing, 1¼" hole through spindle, back geared and friction head. Price.......... $390.00

One No. 3 Pratt & Whitney screw machine, 14" swing, 1" hole through spindle, with wire feed attachment, plain head. Price $325.00

One Davis & Egan No. 3 screw machine, 12" swing with 1" hole through spindle, complete with wire feed, plain head. Price $275.00

One Garvin wire feed screw machine, 12" swing with 1" wire feed capacity, plain head. Price $270.00

One Warner & Swasey plain head turret lathe, 14" swing with 1" spindle capacity. Price $225.00

One Windsor plain head turret lathe, 14" swing with 1" spindle capacity. Price $225.00

One 16" x 5' Gage Fox Monitor brass turning lathe, back gears. Price $300.00

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Toronto, Ont.—A new boiler will be installed at the municipal abattoir.

Petrolia, Ont.—Fred Howlett will build a brick and tile manufacturing plant.

Renfrew, Ont.—The Energite Explosives Co., of Montreal, Que., are building a plant here.

West Lorne, Ont.—The West Lorne Motors, Ltd., will shortly be in the market for new machinery.

Port Arthur, Ont.—It is reported that the Atikokan Iron Co. will equip part of their plant for making munitions.

London, Ont.—The Spray Motor Co. plans to purchase machinery for the manufacture of shells and other munitions.

Toronto, Ont.—Colonel Caldwell has informed Mayor Church that two of the boilers in the old General Hospital where the troops are stationed will have to be renewed.

Port Hope, Ont.—The Standard Ideal Co. have received from the Munitions Committee an order for 60-pdr. high explosive shells, worth over a quarter of a million dollars.

Parry Sound, Ont.—The Canadian Explosives, Ltd., will proceed at once to rebuild the section of their plant at Nobel, near here, which was recently damaged by an explosion.

Windsor, Ont.—The Ontario Cartridge Co., which is being organized, will take over the property formerly occupied by the Steel Products Co. and install machinery for making cartridges.

Collingwood, Ont.—Arrangements are being made to put the plant of the Northern Steel Co. in good repair for the manufacture of steel blanks for shells. Frank B. Baird, of Buffalo, N.Y., has concluded a satisfactory agreement with the Town Council with regard to tax assessment. The plant will be under the immediate control of William Kennedy & Sons, Owen Sound, Ont.

Electrical

Exeter, Ont.—A transformer station will be built here at a cost of $5,000.

Ridgetown, Ont.—The hydro distribution system is nearly completed, and it is expected that power will be turned on shortly.

Milverton, Ont.—It is expected that hydro will be duly installed and ready for service by Christmas. A site has been purchased west of the town for the power station.

Peterborough, Ont.—The Dickson Co. has offered the city electrical energy for the hydro-electric system at $16 per horse-power delivered here, or $13 delivered at Lakefield, where the company can develop 30,000 horse-power when the new Government dam is completed. It is stated that the Ontario Power Commission approves the price.

Municipal

Chatham, Ont.—The city council have decided to submit the Dominion Sugar Co.'s by-law on Jan. 3.

Kingston, Ont.—The city council are in the market for 500 feet of fire hose for the civic buildings.

Princeville, Ont.—The town council are considering the installation of pumps, cast iron pipe and hydrants.

Stratford, Ont.—A new water-main 1,000 feet long will probably be installed on Wellington and Britannia streets.

Galt, Ont.—The city council have agreed to permit the Galt Machine Screw Co. to build on the proposed site at Jackson Park.

Sarnia, Ont. — Sarnia City Council have decided to submit a by-law calling for the expenditure of $12,000 on the extension of the water-mains.

Cornwall, Ont.—A by-law will be voted on by the ratepayers on Jan. 1 to authorize an expenditure of $25,000 on waterworks extensions and pumping equipment.

The Pas, Man.—The town council contemplate spending $80,000 on a sewerage and waterworks system and $50,000 on the construction and equipment of an electric light system.

Newcastle, N.B.—D. A. Jackson, electrical engineer , in a report to the town council recommends the installation of a motor-driven centrifugal pump with a capacity of 350 Imperial gallons per minute. The cost of pump and motor is estimated at $2,000.

Swift Current, Sask.—A motion was unanimously passed at a council meeting recently that the city agents engage a competent engineer to make a thorough examination of the pumping and waterworks system and advise as to what will be required to bring these utilities up to adequate standard and make for a thoroughly efficient system.

General Industrial

Port Dover, Ont.—Port Dover Canning Co. will probably erect a new factory at an estimated cost of $10,000. W. Carson is the manager.

Millerton, N.B.—The New Brunswick Paper and Pulp Co. mill which was recently destroyed by fire will be rebuilt by an Anglo-American concern of which Sir Robert Perks is the main stockholder.

Building Notes

Powassan, Ont.—Contracts have been let for improvements to the Town Hall, to cost $2,710.

Long Branch, Ont.—The big new $36,000 public school is now fairly under way, excavation work going on. The building will cost $26,000, and $10,000 will be spent on the site, which covers more than two acres.

Toronto, Ont.—The Salvation Army have received a building permit for the erection of a three-storey brick and stone training home, costing $90,000, on the north side of Davisville Avenue, near Yonge Street .

Wood-Working

Rainy River, Ont.—A new industry will be established here for making boxes and shingles, etc.

Acton, Ont.—D. A. Henderson will rebuild his sawmill, which was recently destroyed by fire. Loss, $4,000.

Revelstoke, B.C.—D. W. Abrahamson's sash and door factory was destroyed by fire recently. The loss is estimated at $20,000.

Collingwood, Ont.—Wilson Bros. are asking for a loan of $35,000 from the Town Council for the purpose of extending their planing mill and developing their business. H. A. Currie is president of the company.

Tenders

St. Hyacinthe, Que.—Tenders will be received up to January 11, for a mechanical filter plant. Plans and specifications may be obtained at the office of Hector Cadieux, city engineer.

Halifax, N.S.—Tenders will be received by the Governor of the Province of Macao, up till January 8, 1916, for the supply of a steel, self-propelling dredge for the use of the Macao Harbor Works. Full particulars may be obtained at the office of Fred H. Oxley, Consul for Portugal, Keith Bldg., Halifax, N.S.

Toronto, Ont.—Tenders only for all trades required in connection with the erection of a public lavatory on Keele street will be received up to Tuesday, December 7, 1915. Plans and specifications may be seen and forms of tender and all information obtained at the office of the City Architect, City Hall, Toronto.

Halifax, N.S.—Tenders will be received by the Governor of the Province of Macao, up till January 8, 1916, for the supply of a steel, self-propelling dredge for the use of the Macao Harbor Works. Full particulars may be obtained at the office of Fred. H. Oxley, Consul for Portugal, Keith Bldg., Halifax, N.S.

St. Hyacinthe, Que.—The city council will receive tenders until January 11 for excavation, concrete work, superstructure and mechanical equipment required in the construction of a filtration plant with a capacity of 3,000,000 gallons a day. Plans and specifications can be obtained from the engineer, H. Cadieux. Estimated cost, $75,000.

Toronto, Ont.—Tenders for temporary postal station "A," Toronto, Ont., will be received until Dec. 9, 1915. Plans, specifications and form of contract can be seen and forms of tender obtained at the office of Mr. Thos. A. Hastings, Clerk of Works, Postal Station "F," Yonge Street, Toronto, Ont., and at the Department of Public Works, Ottawa.

Winnipeg, Man.—Tenders addressed to the Commissioners of the Greater Winnipeg Water District will be received up to December 15, 1915, for the supply of miscellaneous bronze castings, brass piping, etc., which enter into the construction of a Venturi meter. Specifications and form of tender may be obtained at the office of the District, 901 Boyd Bldg., Winnipeg.

Toronto, Ont.—Tenders will be received by the Chairman, Board of Control, City Hall, up to Tuesday, December 7, 1915, for the supply and erection of a mechanical mixing apparatus for the high-level chlorination plant, Wilton avenue and Don River; also the supply and erection of a mechanical mixing apparatus for the low-level chlorination plant, Eastern avenue and Don River. Specifications and forms of tender may be obtained at the Works Department, Room 6, City Hall.

Toronto, Ont.—Tenders will be received by the Chairman, Board of Control, City Hall, up to Tuesday, December 7, 1915, for the supply and erection of a mechanical mixing apparatus for the high-level chlorination plant, Wilton avenue and Don River; also the supply and erection of a mechanical mixing apparatus for the low-level chlorination plant, Eastern avenue and Don River. Specifications and forms of tender may be obtained at the Works Department, Room 6, City Hall.

Contracts Awarded

New Westminster, B.C.—The City Council has awarded a contract to Vulcan Iron Works, for riveted steel pipe, at $7,000.

Sherbrooke, Que.—The City Council have awarded the contract for gas holders for the new gas works to the Jenkes Machine Co., of this city.

Berlin, Ont.—The City Council have awarded contracts for valves to the Kerr Engine Co., Walkerville, Ont., and cast iron pipe to the Gartshore-Thompson Co., Hamilton, Ont.

Stratford, Ont.—At the meeting of the Public Utilities Commission on Nov. 22, the contract for the installation of the foundation for the new water tower was let to Everett & Marston, of this city.

Trade Gossip

Vancouver, B.C.—The Eclipse Iron Works has been incorporated for $20,000 to do a general iron manufacturing business.

The Canada Nut Co., Vancouver, B.C., has been incorporated with a capital stock of $60,000 to manufacture bolts, nuts, etc.

Quebec, Que.—The new power-house under course of construction at the Transcontinental car shops at St. Malo is nearing completion.

Wallaceburg, Ont.—It is reported that the oil refinery will commence refining about April 1 under a reorganized company. The owners, R. G. Stitt, of Toledo, and C. W. Yates, of New York, were here this week.

Owen Sound, Ont. — The Corbett Foundry and Machine Co. have secured contracts for engine lathes and thread millers, both of which are used in the manufacture of shrapnel and high-explosive shells.

Ottawa, Ont.—Ten million dollars is the capital stock of the British-Canadian Steamship Co., which has been incorporated here this week, with Montreal head office. It has secured wide powers incidental to the carrying on of a general steamship business.

The Barrie Carriage Co., Barrie, Ont., have completed arrangements with the Bell Motor Car Co., of York, Pa., and will manufacture and sell this car in Canada. The present plant will be utilized and the new department will be equipped with as little delay as possible.

The Monarch Machine Tool Co., Hamilton, Ont., have equipped a plant to manufacture lathes, thread millers, cutting-off machines, special tools and machinery for shell-making purposes. Wm. Garlock, Jr., 197 Wellesley street, Toronto, will have charge of the sales and service departments.

School of Navigation.—The second session of the School of Navigation at Queen's University, Kingston, Ont., is to open on December 14th, and continue for three months. The school will be in charge of Capt. H. M. McMaster, assistant superintendent of the Montreal Transportation Co.

Edmonds, B.C.—At a meeting of the Burnaby Board of Trade, held on Nov. 17, W. H. Mansfield, the secretary, delivered an address, advocating the wisdom and necessity of at once taking steps to push Burnaby's claims and advantages for industries. The city has a population of nearly 17,000.

Armstrong Bros. Tool Co., Chicago, Ill., announce that they have been awarded the Grand Prize for tool-holders at the Panama-Pacific Exposition at San Francisco. They were also awarded a medal of honor on other Armstrong products exhibited, including ratchets, drop-forged wrenches, clamps, lathe dogs, etc.

Brockville, Ont.—The Canadian Briscoe Motor Co., who have taken over the Dominion Carriage Co.'s factory, will extend the plant. The company is capital-

ized at $200,000 and the following officers have been appointed: T. J. Storey, president; D. M. Spaidal, vice-president; W. G. Jarman, secretary-treasurer, and and general manager: Ellery Wright, mechanical superintendent.

Vancouver, B.C.—Application is to be made by the Burrard Inlet Tunnel & Bridge Co., through their Parliamentary representatives at Ottawa, Messrs. Pringle & Guthrie, for an extension of the company's charter, which expires on the 3rd of April, next year. Owing to lack of finances, the company finds that they are unable to proceed now with the construction of the Second Narrows Bridge or the other work covered by the company's charter. Consequently an extension of time, probably five years, will be asked for.

Windsor, Ont.—A federal charter has been granted to the Pilcher Manufacturing Co., a new industry in this city. The incorporators are John Vashe Pilcher and George Pegram Walton, manufacturers, Henry Septimus Gray, capitalist, and Charles Lee Hamilton, merchant, of the city of Louisville, Kentucky; and Thomas Porter Archer, of the city of Windsor. The capital stock is $550,000.

Toronto, Ont.—Sir Adam Beck wants the city to submit a by-law to the people on January 1, authorizing an expenditure of $3,000,000 for Hydro radials. The Chairman of the Provincial Hydro Commission declared: "We are up to Toronto on the east with the vote on these radials and we are now coming after them on the west. We can do nothing else until Toronto moves, and I think that the by-law authorizing an expenditure of $3,000,000 for Hydro radials should be submitted as soon as possible." Sir Adam explained that it did not necessarily mean the immediate expenditure of $3,000,000, but the feelings of the people should be sounded, so that their position could be understood.

Toronto Transportation Club held their annual dinner at the Carls-Rite Hotel last Monday evening. The following officers were elected for the ensuing year: President, M. G. Murphy, C.P.R.; Vice-Presidents: Thos. Marshall, Board of Trade; C. E. Horning, D.P.A., G.T.R.; Secretary, W. A. Gray, D.L. & W. Ry; Treasurer, Murdo Macdonald, Grand Trunk Railway; Executive: John Gray, M. H. Brown, B. H. Bennett, D. O. Wood, John Jolly, W. J. Moffat, H. E. Watkins, W. Fulton, J. Stewart, C. B. Brodie, John Thomson. Committee Chairmen: Entertainment, F. V. Higginbottom, C.N.R.; Membership, W. McIlroy, C.P.R.; Sick, John M. Copeland, Chicago & North Western Railway.

Hydro Development is Being Advanced.—Progress is being made by Sir

Over 50 years' experience building hydraulic machinery.

Adam Beck in impressing upon the Ontario Government the importance and necessity of new power development. The Cabinet has had the plans and estimates of the Hydro Commission before it for nearly two months past, but the size of the project has made many conferences necessary between the Ministers and the chairman and his engineers. The new development, which, as Sir Adam Beck announced some time ago, will utilize the overflow of the Welland Canal, will, at the outset, be composed of two units of 50,000 h.p. each. By the time they are ready the consumption of power by the Hydro System will, it is expected, be sufficient to immediately give business to both units. The plans provide for utilizing the Chippewa Creek and carrying the water by an open canal across country to a point below the Whirlpool.

Personal

Gladstone Whitelaw, supt. of the Oxford Foundry, Woodstock, Ont., died on Nov. 29.

George Goodwin, at one time a prominent contractor, died at Ottawa on Nov. 28, aged 72 years.

W. J. McCully has been elected president of the Stratford Board of Trade for the ensuing year. J. Stevenson is secretary.

W. J. Tubman has succeeded James Preston as factory superintendent of the Canadian Allis-Chalmers, Ltd., at Stratford, Ont.

Frank Doty of the Doty Engine Works, Goderich, Ont., has joined the Field Artillery, and is now in camp at Guelph, Ont.

Joseph Harper Harrison, one of the oldest paper box makers in Toronto, died last Saturday night. Deceased was born in Manchester, Eng., in 1849, and came to Toronto at the age of 22.

Capt. W. Murchison, one of the veteran masters of Lake Ontario and Toronto harbor, died on Friday last. Capt. Murchison, who was born in Toronto 65 years ago, sailed on the lakes for over forty years.

Catalogues

Automatic Die-Head made by the Eastern Machine Screw Corporation, New Haven, Conn., is described and illustrated in a bulletin recently issued. The construction of the "H. & G." automatic self-opening die-head is fully dealt with and the various parts illustrated and listed.

Foundry Torch.—Two bulletins issued by the Mahr Manufacturing Co.,

Minneapolis, Minn., describe and illustrate the "Mahr" patent portable foundry torch. The illustrations show the torch being used on various classes of work in the foundry and demonstrate the utility of this appliance.

Barometric Condensers.—Bulletin R., issued by the Mesta Machine Co., Pittsburgh, Pa., illustrates and describes the "Mesta" barometric condenser for steam power plants. The principal features of this type of condenser are dealt with at length, while in addition the bulletin contains a description of the "Mesta" dry air pump.

Moulding Machines.—The catalogue edition of "The Merry Moulder" for September is devoted entirely to a review of the various types of moulding machines made by the Osborn Manufacturing Co., Cleveland, O. A number of excellent illustrations show the various types, and the methods of operation are described, accompanied by the principal dimensions for each size of machine.

"Lagonda" Valves.—The latest publication, N-3, issued by the Lagonda Mfg. Co., of Springfield, Ohio, is a 24-page bulletin on their triple-acting automatic cut-off valves and non-return valves. This book briefly, but completely, discusses the function of these valves, and illustrates the several types made by the Lagonda Mfg. Co., which are the standard angle type and straight way valve, the low squat body valve for low head room, and the horizontal valve. A copy of this bulletin will be sent to any-copy of this bulletin will be sent to interested readers on application.

Book Reviews

Report of the Selby Smelter Commission, by J. A. Holmes, E. C. Franklin, and R. A. Gould. 1915. 528 pp., 41 pls., 14 figs. One volume. Paper covers. $1.25. This No. 98 bulletin describes in detail the methods used, some of them new, in determining the contamination of the air and the damage to trees, crops, and live stock by the smoke and fume from the Selby Smelter, in California, and gives the conclusions of the commission on the methods used by the smelter company to prevent injury. The bulletin is of especial interest to metallurgical companies, municipal or State boards of health, and persons investigating damage by smelter smoke. Owing to the expense involved in the preparation and publication of this bulletin and the limited printing funds available for the use of the Bureau of Mines, it has been necessary to place a price of $1.25 on the work. Orders should not be sent to the Bureau of Mines, but should be addressed to the Superintendent of Documents, Government Printing Office, Washington, D.C.

Trade Gossip

Eden, Ont.—E. Ketchalaw is in the market for woodworking machinery.

London, Ont.—The George H. Beton Lumber Co. will install electrical equipment in its plant to operate woodworking machinery.

Oakville, Ont.—The W. H. Carson brick, sash and door factory on Dundas street, north of Colborne street, was damaged by fire last Saturday to the extent of $10,000.

The Imperial Oil Co., Sarnia, Ont., will increase their capital stock to $50,000,000, to take care of any future possible growth of business. Walter C. Teagle is chairman of directors.

The Imperial Munitions Board have accepted the process of sherardizing cast iron nose plugs for shells as an alternative to nickel-plating. Brass plugs are now being replaced with cast iron ones.

Demand for Old Rails.—With reference to an item regarding the demand for old rails which appeared in the Dec. 2 issue of **Canadian Machinery,** a correspondent advises us that he has a considerable quantity of this material in stock and would like to be put in touch with prospective consumers.

The Canadian Poreclain Co., Hamilton, Ont., have presented to the Hamilton Technical School a fine collection of porcelain insulators used on high tension transmission lines, ranging in voltage from 2,000 to 150,000. The collection will be found valuable in the electrical department of the school for construction in high tension work.

The Canadian Association of Boat Manufacturers at a meeting held in Toronto, elected the following officers:—Hugh Warnock, Penetang, president; M. L. Butler, Brighton, 1st vice-president; W. R. Richardson, of Peterboro', 2nd vice-president; A. F. Fenton, Toronto, secretary; and Herbert Ditchburn, Gravenhurst, treasurer, succeeding Capt. C. H. Rogers, of Peterboro', who is now in France.

Tungsten Advancing. — Prices of tungsten ore and tungsten metal continue to soar. A recent sale of high-grade tungsten ore in the States is noted at $45 per unit for 60 per cent. ore. In September $32 per unit was paid, and in August $16. Tungsten metal or ferro-tungsten is now selling at about $6 per pound of contained tungsten as against 60 cents to 65 cents before the war, and $2.50 a few months ago.

The Steel Company of Canada, Hamilton, Ont., as a result of its increasing business, largely due to the big war orders it has received and the prospect for business after peace is arranged, is planning extensive additions to its plant. Three new open-hearth furnaces are to be built at once, the blooming mill extended and two forge plants erected for the manufacture of 8 and 9.2 shells. The improvement will cost several hundred thousands of dollars.

French Industrial Commission.—Members of the French industrial and Commercial Commission, which recently arrived in New York to promote trade relations between the United States and France following the war, have arranged a tentative itinerary for the next few weeks that will take them to a number of leading cities of the United States and Canada. About Dec. 15 they have arranged to come to Canada for a stay of a week or ten days.

Toronto, Ont.—A by-law seeking permission to guarantee $3,000,000 of debentures as the city's investment in the proposed hydro-electric radial scheme will be submitted to the ratepayers on January 1st next. This decision was arrived at by the Board of Control after conferring with Sir Adam Beck, chairman of the Provincial Hydro-electric Commission, and his chief engineer, F. A. Gaby, on Dec. 1. This amount does not cover the terminals to be located in the city or that part of those radials which constitute a portion of the city's rapid transit. In short the citizens will be asked to meet the cost of all rapid transit lines within the city limits and invest the suggested $3,000,000 in the general scheming outside the city.

Tenders

St. Hyacinthe, Que.—Tenders will be received up to January 11, for a mechanical filter plant. Plans and specifications may be obtained at the office of Hector Cadieux, city engineer.

Halifax, N.S.—Tenders will be received by the Governor of the Province of Macao, up till January 8, 1916, for the supply of a steel, self-propelling dredge for the use of the Macao Harbor Works. Full particulars may be obtained at the office of Fred H. Oxley, Consul for Portugal, Keith Bldg., Halifax, N.S.

Winnipeg, Man. — Tenders addressed to the Commissioners of the Greater Winnipeg Water District will be received up to December 15, 1915, for the supply of miscellaneous bronze castings, brass piping, etc., which enter into the construction of a Venturi meter. Specifications and form of tender may be obtained at the office of the District, 901 Boyd Bldg., Winnipeg.

Personal

John Milne, president of the Burrow, Stewart & Milne Co., Hamilton, Ont., has been appointed to the Senate.

John Ansley, at one time county engineer and also proprietor of the local iron foundry, died at Wingham, Ont., on Nov. 28, aged 83.

P. E. Mercier, acting chief engineer for the City of Montreal, will probably be appointed to that position in succession to the late Georges Janin.

C. L. Jobb, general manager of the Canadian Iron Corporation, has been in Fort William, Ont., for a few days on business connected with the local plant.

Abraham Van Winkle, of the Hanson & Van Winkle Co., died at Newark, N. J., recently aged 77. Mr. Van Winkle, who was born at Pompton, N.J., assisted in the development of the first low voltage dynamo made in the United States.

Charlton James Wollaston, a pioneer in submarine telegraphy, and who laid the first cable from Dover to Cape Gris-Nez, the nearest point on the French shore to that of Britain, died recently in England.

Railways—Bridges

London, Ont.—The council have decided to submit the by-law requested by the London & Port Stanley Railway to raise $101,000 for track extensions.

Brantford, Ont.—At a special meeting of council, it was decided to give ratepayers of the city a chance to vote on ratification of the sale of the Grand Valley Railway between Paris and Galt to the Lake Erie and Northern Railway, which railway is controlled by the C. P.R. between Galt and Port Dover. The cost will be $30,000, and electrification of L. E. and N. Railway from Galt to Port Dover.

London, Ont.—The first step toward the million-dollar guarantee of bonds for the proposed Hydro-radial railway was taken last Monday by the city council, which gave two readings to the by-law and sent it on to the ratepayers.

Hydro Radials.—This proposed Hydro radial scheme includes projected lines running from Western Ontario via London and Guelph, Hamilton to Toronto, Barrie to Toronto, the proposed Markham and Uxbridge line and that section suggested for the connection of Port Perry with Toronto via Whitby. Sir Adam's Beck idea is to make Toronto the real pivotal point of all the adjacent counties, and latterly, the Province for

farming, market gardening and other industries, as well as for passenger traffic.

Radial Plans Approved.—The Toronto-Guelph-Berlin-London Hydro Radial project was further advanced on Nov. 23 when a deputation of municipal representatives from Mimico and New Toronto discussed with Chief Engineer Gaby, of the Provincial Hydro-Electric Commission, at Toronto, route plans and other points in connection with the line. This conference was one of a number the commission's engineers are having with the representatives of the various municipalities interested in order to secure approval of plans and details.

New Incorporations

The Eclipse Iron Works, Ltd., of Vancouver, B.C., has been incorporated with a capital of $20,000.

The Eastern Machinery Co. of Montreal has been incorporated with a capital of $45,000. Incorporators: A. Lalonde, E. A. Lalonde and D. L. Desbois, all of Montreal.

The Dominion Shell Mfg. Co. of Montreal has been incorporated with a capital of $99,000. Incorporators: H. C. Thorn, L. H. Cote and W. W. Laindon, all of Montreal.

The Dominion Magnesite Co. of Calumet, Que., has been incorporated with a capital of $100,000. Incorporators: F. G. Bush, G. R. Drennan and M. J. O'Brien, all of Montreal.

The Lachance Nut Lock Co. has been incorporated with a capital of $300,000 to carry on business at Montreal, Que. Incorporators, J. A. Bilodeau, M. Loranger and B. Melaveon, of Montreal.

The Kirkland Lake Gold Mining Co. has been incorporated at Toronto, with a capital of $2,000,000, to acquire and develop mineral lands and deposits. Head office at Toronto. Incorporators—David Inglis Grant and Gideon Grant, of Toronto.

The Triumph Mines, Ltd., has been incorporated at Toronto, with a capital of $3,000,000, to acquire and develop mineral lands and deposits. Head office at Toronto. Incorporators—James Richardson Roaf and John Edward Morden, of Toronto.

The Canadian Vincent Valve Co. has been incorporated at Ottawa with a capital of $25,000 to manufacture the Vincent drain valve and similar appliances at Victoria, B.C. Incorporators: Arthur Newham, R. Powell and E. Bonner, all of Victoria, B.C.

The Alliance Beverage Co. of Toronto has been incorporated at Toronto, with a capital of $40,000, to manufacture beverages, condiments, preserves, etc., at Toronto. Incorporators—Henry Cresser Haskins and Edward Gowan Russell Aradagh, of Toronto, Ont.

The Federal Brass Co. has been incorporated at Ottawa with a capital of $50,000 to acquire the business now carried on by the Federal Electric & Mfg. Co. at Montreal. Incorporators: Joseph Phillipe Arthur Belanger and Louis Joseph Cyprien Gagnon of Montreal.

The Canadian Brass Bedsteads, Ltd., has been incorporated at Ottawa with a capital of $45,000 to manufacture household furniture of all kinds and in particular brass and iron bedsteads, at Montreal. Incorporators: Eugene Honore Godin and Joseph Eudore Morier, of Montreal.

Canadian Canners, Ltd., has been incorporated at Ottawa with a capital of $1,000,000 to carry on business as manufacturers of all kinds of canned goods, condiments, pickles, etc., at Toronto, Ont. Incorporators: John Dawson Montgomery, Arthur Carson McMaster, of Toronto.

The Pilcher Mfg. Co. has been incorporated at Ottawa with a capital of $50,000 to manufacture metal buttons and other goods, at Windsor, Ont. Incorporators: John Vashe Pilcher and George Pegram Walton, of Louisville, Kentucky, and Thomas P. Archer, of Windsor, Ont.

The Canadian Electro Products Co. has been incorporated at Ottawa with a capital of $500,000 to manufacture all kinds of metals, metallic substances, metallic products, chemicals, etc., at Montreal. Incorporators: Walter Robert Lorimer Banks and Daniel Percy Gillmor of Montreal.

The Western Sugar Refining Co. has been incorporated at Toronto, with a capital of $600,000, to manufacture, refine sugar and by-products at Petrolia, Ont. Incorporators: Ralph Daniel Mitchell and Daniel Joseph Kilby, of Cleveland, Ohio, and David A. Gordon, of Wallaceburg, Ont.

The Imperial Cordage Co. has been incorporated at Ottawa with a capital of $150,000 to manufacture rope, binder twine, and all products and by-products of manila, hemp and sisal, at Walkerton, Ont. Incorporators: John Connor, of St. John, N.B., E. A. D. Morgan and S. Avery of Montreal, Que.

Contracts Awarded

Toronto, Ont.—The city council have awarded a contract, lead-covered underground cable, to the E. F. Philips Electrical Works, Ltd., Montreal.

Kingston, Ont.—The City Council have awarded a contract for rubber lined linen fire hose to the Goodyear Tire & Rubber Co., Toronto, at 50c per foot.

Merrickville, Ont.—The Rideau Power Co., have awarded contracts for water wheels to the William Hamilton Co., Peterborough, and electrical equipment to the Swedish General Electric Co. The total cost of power house and plant is estimated at $80,000.

Catalogues

Oiling Devices made by the Canadian Winkley Co., Windsor, Ont., are the subject of catalogue No. 10. A large number of styles are illustrated and described in detail, accompanied by price list and principal dimensions for each size.

The Canadian General Electric Co., Toronto, Ont., have issued a bulletin illustrating and describing a new multi-stage centrifugal compressor set No. 3350. This machine is particularly applicable for use in connection with oil or gas-burning furnaces and a list of operating advantages is given.

Buffing and Polishing Machinery.—Bulletin No. 700 on buffing, polishing and burnishing machinery, the latest of the series of "Munning-Loeb" publications on electro-plating and polishing equipment and supplies, fully describes the Munning-Loeb line of buffing and polishing lathes from the small bench lathes to the large double-spindle pedestal lathe, also belt strapping machines, flexible grinders, tumbling barrels, burnishing barrels and sand blast apparatus. This bulletin will be sent to anyone on request.

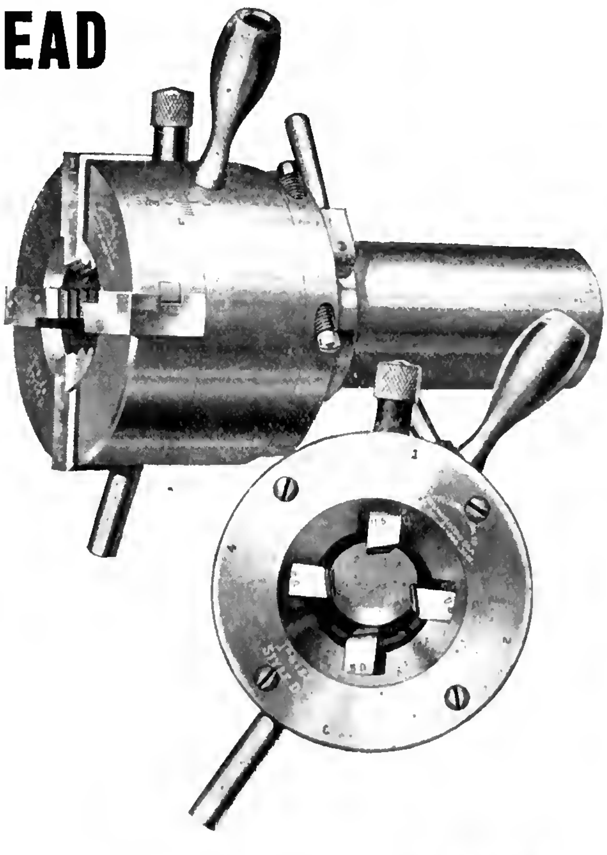
Motor Generator Sets.—Bulletin No. 42,552 issued by the Canadian General Electric Co., Toronto, illustrates and describes an interesting and varied range of motor generator sets adapted for different purposes. The bulletin contains a considerable amount of information covering the operation, field of application, excitation and construction of motor generators, while booster and balancer sets are also dealt with. The bulletin contains a number of excellent halftones covering the various types and showing in a general way the design and arrangement when installed.

Lubricators.—Bulletin No. 60, the Richardson model "M" sight feed oil pump recently issued by the Richardson-Phenix Co. of Milwaukee, Wis., contains much new information concerning the

well-known model "M" lubricator. Interesting illustrations show the process of manufacture from the raw material to the finished lubricators on the test rack, and give a good idea of the manner in which the pumps are drilled and milled from a solid block of cast iron. An interesting chapter on gas engine lubrication discusses the question of timing the admission of oil so that it is forced directly on to the engine pistons. Other items of interest are a description of the new Richardson air spray attachment; also the steam and electric attachments for heating the oil in the lubricator reservoir. A double-page illustration of the New York sky-line shows that practically all important buildings in the Metropolitan district are equipped with Richardson-Phenix lubricating appliances. Copies of the above bulletin may be had upon request from the company.

Book Reviews

The Model T Ford Car, its construction, operation and repair, by Victor W. Page, 300 pages, 5 x 7, 100 engravings and two folding plates. Published by the Norman W. Henley Publishing Co., New York City. Price $1. This is the 1916 edition of a book which, as the title indicates, is written chiefly for owners, dealers and salesmen of Ford cars. Although the book deals exclusively with one particular make of car, the fact that so many Ford cars are in operation makes the situation somewhat exceptional, and warrants the publication of a special treatise on its repair and maintenance, especially as so many owners of Ford cars possess but little mechanical knowledge. The volume as a practical instruction book is complete and the subject is treated in a comprehensive manner. The construction is fully described and the operative principles made clear to everyone. Complete instructions for driving and repairing are given, while every phase of the subject is treated in a non-technical manner. The book contains five chapters. The first deals with the Ford car with regard to its parts and their functions. Chapter 2 describes the engine and the various auxiliary groups. The details of the Ford chassis parts are dealt with in chapter 3, while chapter 4 contains instructions for driving and the maintenance of the car. The concluding chapter on overhauling and repairing the mechanism is of special value and contains a great deal of valuable information. The diagrams and half-tones, which are full of detail, have been carefully prepared and are very instructive. The book is fully indexed, printed in clear type, and is bound in cloth.



company who propose establishing a plant to manufacture wood alcohol, charcoal and acetic acid. Thomas Hodgson is promoting the company.

Toronto, Ont.—Parks Commissioner Chambers has recommended to Board of Control that three stand-pipes, the necessary quantity of fire hose, and three portable extinguishers be installed at the Process Building at the Exhibition grounds, where the soldiers are accommodated. The cost of the equipment will be $255.

Petrolea, Ont.—The council on Dec. 7 gave first and second readings to the by-law for $21,500 to assist the Western Sugar Refining Co., which will locate here, if this inducement is granted. A by-law to raise $25,000 to purchase stock in the company was twice read. These issues will be voted upon by the ratepayers January 3.

Electrical

St. Thomas, Ont.—The Michigan Central Railway will electrify their terminal at this place.

Hull, Que.—The city council are considering extensions to the lighting system, estimated to cost $20,000.

Biddulph Township, Ont.—A by-law has been passed providing for the installation of a hydro-electric system at an approximate cost of $3,500.

Burgessville, Ont.—A by-law to provide for the construction of a hydro-electric system at an approximate cost of $3,500 will shortly be submitted by the township council of South Norwich.

General Industrial

St. Catharines, Ont.—Fire on Dec. 7 destroyed the Maple Leaf Milling Co.'s flour mill here. The loss is estimated at $75,000, which is fully covered by insurance.

Davidson, Sask.—The Canadian Elevator Co. will build an extension to their elevator. The North Star Elevator Co. and the British American Elevator Co. will also enlarge their mills.

Vancouver, B.C.—The Canada Potash and Algin Co. will shortly work on a new plant for making iodine and gum algin. These materials will be made from kelp, which is found in large quantities along the coast.

Sackville, N.B.—The A. E. Wry Standard, Ltd., factory was damaged by fire on December 5, the loss being estimated at $35,000, of which $20,000 is covered by insurance. The company manufacture harness and other leather goods.

Toronto, Ont.——The factory of T. Crowley & Co., manufacturers of picture frames, on McDonnell Square, was badly damaged by fire on Dec. 12. The damage is placed at about $1,500 to the building and $7,000 to the stock and contents. The loss is covered by insurance.

Contracts Awarded

The Otis-Fensom Co., Hamilton, Ont., have been awarded a contract for an elevator by the Patterson Mfg. Co., of Montreal, Que.

Port Moody, B.C.—The contract for the construction of a waterworks system has been awarded to the Robertson-Godson Co., Vancouver, B.C., at $37,000.

Toronto, Ont.—The Board of Control has awarded a contract for the supply and installation of valves, steam piping, special steel castings and lagging at main pumping station to Purdy, Mansell, Ltd., at $19,995.

Brockville, Ont.—The Public Utilities Commission at a meeting on Dec. 7 awarded the contract for the new filtration plant to the Roberts Filtration Company, of Darby, Pa., for $86,000, and also requested the Town Council to provide $115,000 to cover the filtration plant, low lift pumps and intake cost.

Tenders

St. Hyacinthe, Que.—Tenders will be received up to January 11, for a mechanical filter plant. Plans and specifications may be obtained at the office of Hector Cadieux, city engineer.

Halifax, N. S.—Tenders will be received by the Governor of the Province of Macao, up till January 8, 1916, for the supply of a steel, self-propelling dredge for the use of the Macao Harbor Works. Full particulars may be obtained at the office of Fred H. Oxley, Consul for Portugal, Keith Bldg., Halifax, N.S.

Winnipeg, Man.—Tenders will be received up to Monday, December 27, 1915, for the supply of one saddle tank locomotive to the Greater Winnipeg Water Commission. Specifications and form of tender may be obtained and contract may be inspected at the offices of the district, 901 Boyd Building, Winnipeg, Man.

Winnipeg, Man.—Tenders addressed to the undersigned will be received up to Wednesday, December 29, 1915, for the supply of twenty twenty-yard automatic air-dump cars. Specifications and form of tender may be obtained and form of contract may be inspected at the office of the district. S. H. Reynolds, Chairman of the Greater Winnipeg Water Commissioners, 901 Boyd Building, Winnipeg, Man.

Trade Gossip

The Shawinigan Electro Metals Co. have increased the capital stock of the concern to $200,000.

The International Steel Corporation, Ltd, have changed the name of the concern to Canadian Iron Ores, Ltd.

The Turnbull Elevator Co., Toronto, have been awarded a contract for the elevators for the Crompton Corset Co.'s new warehouse.

Simcoe, Ont—The Town Council will submit a by-law for the establishment of a Utilities Commission to take over the waterworks sewage disposal plant and the hydro system.

The Canada Steamship Line, Montreal staff have enlisted for overseas service. The eligible men are to be enlisted in one battalion, and officers, who are to go to Halifax at once to qualify for commissions, will lead the company. There are forty-six Canada Steamship Line in the trenches now.

Kingston, Ont.—The announcement of United States Consul F. F. Johnson last Monday shows the export trade from this port to the States for the year 1915 to have reached the million dollar mark, giving Kingston third place in the Dominion, with Toronto first and Ottawa second.

Toronto, Ont.—It is reported from La Porte, Ind., that the plants of the M. Rumley Co., and Rumley Products Co., capitalized at $32,000,000, were bought in at receiver's sale for $4,000,000 on Dec. 9 by reorganized Rumley companies. The Rumley Co. have a branch in this city.

Toronto, Ont.—Roads to the extent of 250 miles have been permanently improved and macadamized in various parts of the Province of Ontario this year. On colonization roads $220,078.19 has been spent. The total cost of the Hamilton-Toronto highway will be about $900,000. The estimated cost was $600,000.

Montreal, Que.—The shareholders of the Canada Cement Company, at a special meeting recently unanimously authorized an application for supplementary letters patent permitting the company to embark on the manufacture of war munitions. General Manager Jones gave an optimistic forecast of the results expected from the business, and the shareholders were informed that no new financing would be necessary.

Montreal, Que.—Three departments of the Grand Trunk Railway shops at Point St. Charles were gutted by fire which broke out at noon on Dec. 10 in the tube

shop and spread to the blacksmith shop and the erecting plant. The fire was caused by a tube striking and breaking an oil pipe, the oil igniting and flowing in all directions. The tube shop, blacksmith shop and part of the erecting shop were destroyed.

Toronto Harbor Works.—It is announced that the Toronto harbor work in the vicinity of Cherry Street is to proceed as weather permits. The Canadian Stewart Co., the contractors, have undertaken to make good the defective construction by a sub-contractor disclosed upon examination by Government experts, and the work will proceed without further hitch in favorable weather. The restoration of the imperfect construction will be done without cost to the Government, it is said. The contractors say there will be no unnecessary delay.

Grain Moving on N. T. R.—Arrangements have now been completed for the official inspection, weighing and grading of grain at Winnipeg so that grain consigned by the N. T. R. will not have to go first to Fort William or Port Arthur. At present all certificates are granted at the head of the lakes. At Halifax, where most of the grain handled will be shipped, Mr. Cochrane has made arrangements for the storage of some five hundred cars, so that the grain will be protected until shipped. There is no elevator accommodation at Halifax. The Government expects to get a large share of the winter all-rail shipments.

National Steel Car Co.—In a letter to the shareholders, Vice-President Basil Magor states that the company has orders aggregating $8,000,000 for rolling stock to be used on foreign railways, as well as other large contracts, and in addition the company is building steel sleeping coaches, first-class coaches and motor trucks. Mr. Magor states that the fiscal year ending on November 30 will show approximately $450,000 of profits, and that, therefore, if the dividend liability is removed without depleting too much the working capital, the company's position will be substantially improved.

Personal

Frederick Powell, president of the Rideau Lumber Co., Ottawa, Ont., died on December 3.

W. G. Worden, a graduate of Toronto University, has been appointed town engineer of Oshawa, Ont., to succeed F. A. Chappell, who has resigned.

E. M. Smith, president of the American Shipbuilding Co., who owns the dry dock at Port Arthur, Ont., died suddenly at Buffalo, N.Y., on Dec. 8.

A. G. McAvity, manager of the Canadian Blower & Forge Co., Berlin, Ont., has been engaged by the Imperial Munitions Board in an advisory capacity.

Lieut. F. Y. Harcourt, who for several years has been district harbor engineer at Port Arthur, Ont., has received a commission in the 94th Battalion of the C.E.F.

W. L. Helliwell, manager of the Gurney Northwest Foundry Co., Winnipeg, Man., has been appointed to a more important position on the staff of the firm at the head office in Montreal.

Thomas J .Walsh, chief operating engineer of the high-level pumping station, Toronto, Ont., who had been in the civic service for a long number of years, died on Dec. 12 at his home, 40 Rathnally Avenue, in his 55th year.

H .S. Carmichatel has been appointed freight and passenger agent at London, England, of the Canadian Pacific Ocean Services. He completes twenty years' service with the C. P. R. this week. H. S. Dring succeeds him as passenger agent of the C. P. R.

L. C. Ord, assistant works manager, Angus car shops, C. P. R., Montreal, Que., has been appointed Lieutenant in No. 1 Overseas Battery of the Siege Artillery, C.E.F., and has been granted leave of absence for active service. Lieutenant Ord sailed from Halifax for the front November 22nd.

F. Perry has been appointed a member of the Imperial Munitions Board. Mr. Perry has for some years represented in Canada a large private banking house of London. At one time he was attached to the British Colonial Office, and later was Imperial secretary to Lord Milner in South Africa and chairman of a native labor association in South Africa.

New Incorporations

The York Paper Box Co. has been incorporated at Toronto, with a capital of $40,000, to manufacture all kinds of paper boxes, etc., at Toronto. Incorporators: James Douglas Woods and William Batten McPherson, of Toronto.

The Chemical Refinery, Ltd., has been incorporated at Ottawa, with a capital of $100,000, to manufacture drugs, chemicals and fertilizers at St. Catharines, Ont. Incorporators: John P. Mitchell, Harry W. Page and W. P. Crow, all of Toronto.

The J. S. Lewis & Sons, Ltd., has been incorporated at Ottawa, with a capital of $100,000, to carry on the business of lumbering and manufacturing of wood and other materials at Truro, N.S. Incorporators: George Ezra Morton Lewis and Frank Leslie Lewis, of Truro, N.S.

Railways—Bridges

Brantford, Ont.—It is understood that arrangements are practically completed for the creation of a Union Radial Station in this city to be used jointly by the Brantford and Hamilton and Lake Erie and Northern Railways. The intention is to place it on the old site of the Brantford Ice Co., and it will cost approximately $30,000.

Berlin, Ont.—By a vote of eight to four the City Council decided on Dec. 6 to submit a hydro-radial by-law for $779,000 to the ratepayers. Waterloo Town and Waterloo Township Councils also voted in favor of submitting similar by-laws, the former for $193,000, and the latter for $521,903. Engineer F. A. Gaby, of the Ontario Hydro-Electric Commission, attended all three meetings. The route through Berlin agreed upon by the citizens was not defined in the by-law.

Building Notes

Toronto, Ont.—A building permit has been issued to W. H. Harris, in trust, for the erection of a two-storey brick mill construction warehouse on the north side of Richmond Street, near John Street, costing $18,000.

Wood-Working

Calgary, Alta.—The Rumley Co. propose building a warehouse here and make the city a distributing centre.

Hamilton, Ont.—Spontaneous combustion started a blaze in the Semmens & Evel casket factory on December 7, and did $2,000 damage.

Deseronto, Ont.—The Canada Hardwood Mfg. Co. is in the market for sawmill and wood-working machinery, automatic lathes, belting, etc.

Marine

Port Arthur, Ont.—The Western Dry Dock & Shipbuilding Co.'s plant will be working to capacity during the coming winter months. The company have on hand several freighters for lake service.

Port Arthur, Ont.—Freight rates from Port Arthur to Buffalo have risen from a rate of from three and a half to four cents a bushel, which prevailed during the regular season, to five and a half cents.

North Vancouver, B.C.—The City Council will immediately take steps to offer some inducements for the establishment of a drydock on the North Shore. The Board of Trade will support the scheme.

John L. Nelson, who came to the Province of British Columbia in March, 1913, as superintendent of dredging, has sent in his resignation to the Department of Public Works.

Port Arthur, Ont.—The Canadian steamer, W. Grant Morden, the longest boat on the lakes, left on Dec. 9 for Port McNicoll with 760,000 bushels of oats, the largest cargo ever taken from this port, being equivalent to 400 loaded cars.

Brockville, Ont.—The Department of Marine and Fisheries has awarded the contract for the erection of a lighthouse one the river front at Fulford's Point, west of here. The building will be twenty feet high with concrete foundation.

Collingwood, Ont.—The steamer Hamonie of the Northern Navigation Co.'s Lake Superior fleet is coming to Collingwood about Dec. 15th and will probably remain throughout the winter. The object of the visit is to go to the dry dock for repairs.

Catalogues

Milling Machines.—A bulletin issued by the Fox Machine Co., Grand Rapids, Mich., describes and illustrates the "Fox" No. 3 hand and power feed milling machine. A specification is included giving the principal dimensions and shipping weights, etc.

Air Heater and Air Blower.—Bulletin No. 219, issued by the B. F. Sturtevant Co., Boston, Mass., deals with the "Sturtevant" electric air heater and blower. The apparatus is fully described and the various purposes for which it can be used are given in detail. A list of sizes with capacities is included and the illustrations show a few different types indicating their varied application.

Friction Clutches made by the Carlyle, Johnson Machine Co., Manchester, Conn., are illustrated and described in catalogue E, recently issued. The various classes of work for which this clutch is suitable are described separately with illustrations showing the mountings. Tables are included giving the principal dimensions, accompanied by diagrams showing to what part the dimensions refer. Other equipment for use with these clutches is also described and illustrated.

Oxy-Acetylene Apparatus.—The L'Air Liquide Society of Montreal, Que., have issued a folder containing a number of leaflets describing their oxy-acetylene apparatus for welding and cutting. The many types of blowpipes for various purposes are described fully and tables give the capacity for each size. Other leaflets describe and illustrate acetylene generators. A number of welding supplies and materials are dealt with in detail, accompanied by price lists. The leaflets are fully illustrated and included in views of the plants at work.

The Phenix Force Feed Lubricator, Bulletin No. 50, recently issued by the Richardson-Phenix Co. of Milwaukee, Wis., contains a complete description of the Phenix ratchet type lubricator; it also describes a new type, known as the model "T." The catalogue contains an interesting diagram, giving a comparison of the way in which mechanical and hydrostatic lubricators feed oil to engine cylinders. Numerous illustrations show the application of the Phenix lubricator to different types of engines, pumps, steam hammers, etc.

Establishing and Maintaining Boiler Room Economy is the title of a paper presented before the Ohio Society of Mechanical, Electrical and Steam Engineers, by Geo. H. Gibson, developing the thesis that the most important requisites to further improvements of boiler plant economy are means of recording boiler performance—that is, of determining the number of pounds of water evaporated per pound of coal. Information obtained sporadically, as by means of short boiler tests, is not so suitable for this purpose as is information supplied continuously, as by a feed water meter. The relative values of different kinds of coal, the improvement in evaporation following cleaning of soot and scale off heating surfaces, or the stopping up of air leaks, the relative merits of different methods of firing, are then readily demonstrated, and scientific management becomes easy and natural. That is, the ways and means of attaining a certain standard of performance having been demonstrated, the management is in a position to ask for good results continuously; in fact, standard rules of operation—that is, directions as to methods of handling fires, regulation of draft, blowing of soot, banking fires, carrying over-loads, etc., can be written out, so that any man following instructions can obtain good results. The installation further arouses the pride of the engineer, and makes it possible to reward skill or attention to duty. This pamphlet is being distributed by the Harrison Safety Boiler Works, Philadelphia, Pa.

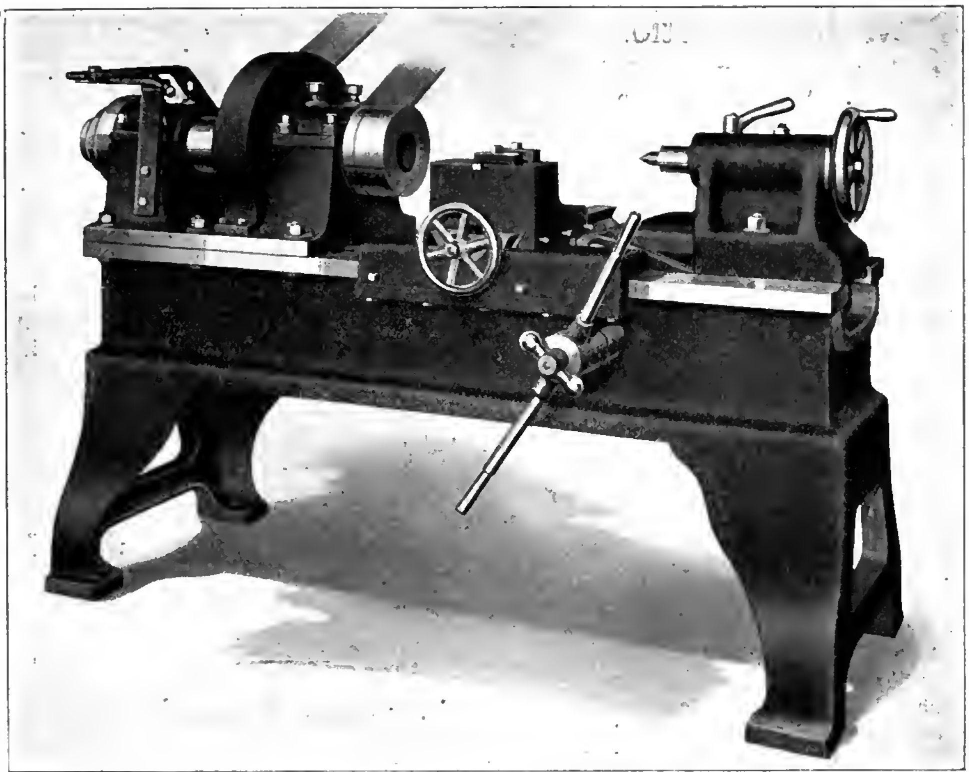
(Patents Applied For)

THIS MACHINE TOOL IS AN EXCELLENT EXAMPLE OF SPEED, ACCURACY, POWER, STRENGTH AND SIMPLICITY—ITS SERVICE GIVES YOU MORE MARGIN FOR PROFIT.

Drop us a card for specification and full details.

Prompt delivery.



The A. R. Williams Machinery Co. LIMITED

64-66 Front Street W., Toronto, Canada. St. John, N.B., Winnipeg, Vancouver.

IF IT'S MACHINERY—WRITE "WILLIAMS"

WE ARE NOT GOING TO GIVE YOU UP

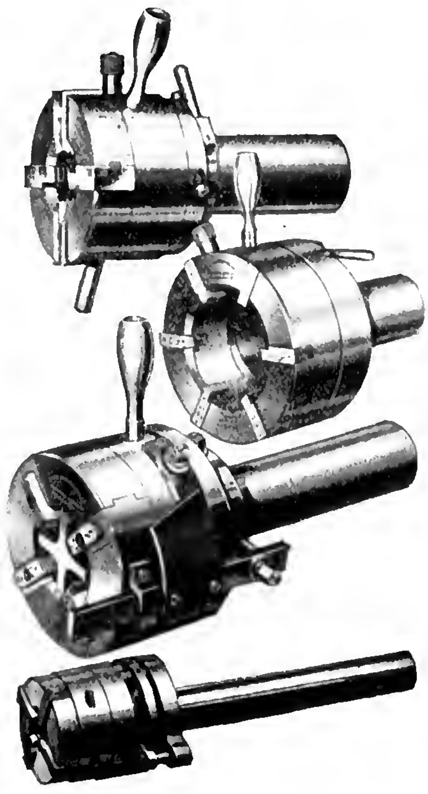
We have a Geometric Self-Opening and Adjustable Screw-Cutting Die Head for you, and we want you to have it.

The big manufacturers are using them, and the smaller manufacturers cannot afford to do their thread cutting without them.

Geometric Self-Opening Die Heads, that release the work when the required length is reached, are furnished for cutting from 1-16-inch diameter up to the largest requirement, of any pitch and form.

Can be arranged for use on any make of Screw Machine.

Let us know the line of thread cutting you have to do, and we will send you full particulars of the Die Head.



THE GEOMETRIC TOOL CO., New Haven, Conn., U.S.A.

Canadian Agents:

Williams & Wilson, Ltd., MONTREAL

The A. R. Williams Machinery Co., Ltd., TORONTO, WINNIPEG, ST. JOHN, N. B.

New Incorporations

The Manchester Ironworks, Ltd., of Calgary, Alta., have been incorporated with a capital of $50,000.

The Canadian Northern Ontario Railway Co. is applying for an extension of time for the construction of its authorized lines from Toronto to Windsor, St. Thomas and Sarnia.

The International Exploration Co., of Montreal, has been incorporated at Ottawa, with a capital stock of $2,000,000, and authority to do all kinds of prospecting and development work.

The Three-O-System Co. has been incorporated at Ottawa, with a capital of $250,000, to manufacture stoves, boilers, furnaces, etc., at Toronto. Incorporators: Fred Holmes and E. A. Douglass, of Toronto.

The Canadian Electrode Co. has been incorporated at Ottawa, with a capital of $100,000, to manufacture electrical and other equipment at Montreal. Incorporators: Howard Murray and Wm. S. Hart, of Montreal.

The Ontario Niagara Connecting Bridge Co. has given notice of application to Parliament at Ottawa for an Act of Incorporation, with power to construct and operate a railway and traffic bridge over the Niagara River.

Brantford, Ont.—The city is applying for legislation empowering the corporation to own, operate and extend the Grand Valley Railway under the name of the Brantford Municipal Railway System.

The Canada Cement Co., Montreal, Que., has been granted supplementary letters patent empowering the company to go into the iron and steel manufacturing business, including the manufacture of all kinds of munitions and the development of mines.

Marine

Owen Sound, Ont.—The tugs C. M. Bowman and Maud L. were destroyed by fire on Dec. 13 at Vail's Point harbor, about six miles from here. While cleaning the flues of the Maud L. with a jet of steam, a back draft of soot exploded and blew the fire out of the firebox under the boilers and ignited the woodwork. Captain Geo. Dunn was the owner of both tugs.

Montreal-Longueuil Ferry.—The close of the season of navigation as regards ocean and lake vessels is now succeeded in its turn by the close of the season within the port of Montreal. The Longueuil ferries, Louis Phillippe and Boucherville, have now gone to their winter quarters in the Basin opposite Shed No. 11. The sheds along the Canada Steamship Lines piers have been lifted on to three steam barges berthed at the same place.

Sarnia, Ont.—The steamer Majestic, owned by the Northern Navigation Co., was totally destroyed by fire on Dec. 15 as she lay at the dock at Point Edward, and was responsible for a serious fire on the steamer Saronic, which was moored alongside. The Majestic was operated on the Georgian Bay run from Cleveland and Detroit, and made special excursions each summer. She was built in Collingwood in 1895, and was 209 feet in length, with a beam of 39 feet. The loss is placed at $100,000, and the insurance at $90,000 on the Majestic. The loss on the Saronic is estimated at $25,000.

Contracts Awarded

Fort William, Ont.—The contract for an addition to the plant of the Fort William Coal Dock Co., on Mission River, has been awarded to Roberts & Schaefer Co., Chicago, Ill. Estimated cost, $300,000. C. B. Nineaber, General Manager.

Burnaby, B.C.—The Shell Oil Co., Vancouver, have let the contract for docks, approaches and bulkheads, in connection with the construction of their oil plant on Burrard Inlet, to the Vancouver Pile Driving and Contracting Co., Vancouver.

Railways--Bridges

Milton, Ont.—The hydro-radial bylaw will be submitted to the ratepayers on January 3.

Guelph, Ont.—It is expected that the Toronto Suburban Railway to Guelph will be in operation as far as Georgetown by February 1 and to Guelph by March 1.

Brantford, Ont.—It is reported that a union station will be built here to cost approximately $30,000. It will be used jointly by the Brantford and Hamilton, and the Lake Erie & Northern railways.

Quelph, Ont.—The Council of Puslinch township, through part of which the proposed Hydro-radial line runs, has decided not to submit the by-law at present to raise the $70,300, the share apportioned to that municipality. Eramosa township has not yet decided on the matter, although several meetings have been held to discuss the proposal.

Building Notes

Toronto, Ont.—The Dominion Bridge Co. will supply the steel work for the Imperial Oil Co. new office building.

Hamilton, Ont.—The Canadian Cartridge Co. have secured a building permit for an addition to their factory.

Quebec, Que.—A building permit has been issued to the Public Service Corporation, who propose building a pumping station.

Refrigeration

St. Boniface, Man.—A municipal abattoir will be established here at a total approximate cost of $300,000. It will be located near the Union Stockyards.

Fort Frances, Ont.—It is rumored that Gordon and Ironsides, the meat packers, are contemplating building a branch packing house here. A large storage warehouse with ammonia plant for freezing will be built.

Catalogues

Sand Blast Machines.—The New Haven Sand Blast Co., New Haven, Conn., have issued a bulletin illustrating and describing their automatic sandblast machine. Two types of machine, high and low pressure, are described and some of the principal features of their construction dealt with in detail.

The Sterling Lines is the title of supplement No. 1 to catalogue 11024, issued by the Sterling Wheelbarrow Co., Milwaukee, Wis. The equipment dealt with includes different styles of steel foundry flasks for a large variety of work. Each style is illustrated and its principal features described at length. The catalogue is illustrated in an attractive style.

Air Brushes.—The Paasche Air Brush Co. have issued a booklet No. 10 describing a complete line of air brushes and attachments. The different models of air brushes are dealt with in detail and method of operation described. The various parts and attachments are illustrated and described in detail, while prices and other information is included with each.

Rotary Planing Machines, made by the Newton Machine Tool Works, Inc., are illustrated and described in catalogue No. 50. Each of the various types is illustrated and briefly described and a general specification is included. A section of the catalogue, printed on colored paper, deals with slotting ma-

chines, cold metal saws, milling, boring and planing machines, etc. In this section a number of types are illustrated and the principal dimension given for the various sizes. Other illustrations show rotary planing machines in operation. The catalogue contains 36 pages, and is gotten up in an attractive style.

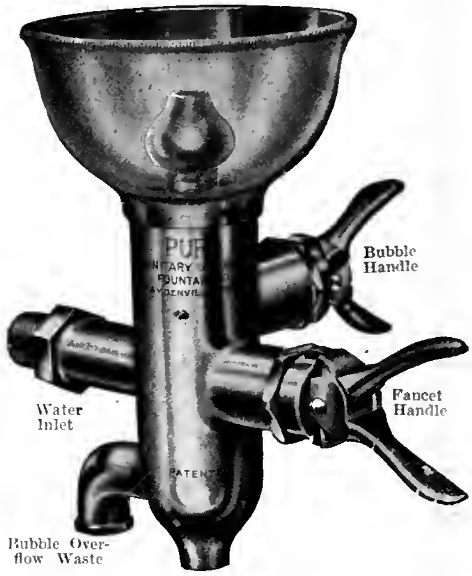
Metal Cutting Saws.—The Simonds Mfg. Co., Fitchburg, Mass., have issued a very attractive catalogue dealing with their various products, which include metal saws, hack saws, files, machine knives, saw blades, etc. The various lines are illustrated and are accompanied by tables giving particulars and prices of the different sizes. A complete price list of files and saws is included, as well as for hack saw blades. Several pages are devoted to different methods of cutting steel and contain much valuable material on the subject for the buyer, dealer and operator. A copy of this catalogue will be sent free to any machinist writing for it.

Book Reviews

The "Mechanical World" Pocket Diary and Year Book for 1916. Published by Emmott & Co., Ltd., Manchester, England. Price, 25c. The twenty-ninth issue of this extremely useful little publication is now on sale, and, as is the usual custom, additional information has been introduced. The section on steam boilers has been largely rewritten and enlarged, including particulars of boiler scantlings, the requirements as to boiler mountings, etc. A separate and enlarged section is now devoted to the Diesel engine, embodying a good deal of concisely arranged data which will be appreciated by designers. Some notes on brazing and soldering have also been introduced. Among the several new tables, mention may be made of those relating to Lancashire and Cornish boilers, dimensions of locomotive boilers, steel plates, friction clutches, circle spacing table, etc. Other tables have been extended, and the book generally has been thoroughly revised. The book contains 264 pages full of useful engineering notes, rules, tables and data, etc.; while in addition there is the usual diary, index and advertising matter, a total of 429 pages. The book is fully illustrated and bound in substantial cloth covers.

SITUATIONS VACANT

POSITION OPEN — TWO FIRST-CLASS machine shop foremen, with thorough experience in tooling up and operating a plant for the larger sized high explosive shells. Only men with excellent references covering this class of work need apply. To receive attention, full particulars must be given in the first instance, of experience, by whom previously employed, age and salary expected. Box 161, Canadian Machinery. (1)



TRADE, COMMERCE, AND TRANSPORT

Embracing Statements of Manufacturing Output, Records of Imports and Exports, Company Statistics, Provincial Revenues and Trade Possibilities, Etc.

CANADIAN SHIPBUILDING DURING 1915.

DESPITE the fact that the manufacture of munitions has in large measure displaced that of other steel and iron products, shipbuilding and ship-repairing in Canada may be said to have maintained at least its average activity in both departments. The conclusion of the war, and, of necessity, probably earlier, will witness an enlargement of both shipbuilding and marine engineering production everywhere, and we in Canada cannot fail to participate to some extent, even be it but to fill our own needs, which are daily becoming more pressing. The following details covering the work of the year 1915 have come to hand:

Collingwood Shipbuilding Co.

This establishment is enjoying considerable activity in new work, having launched on the 15th of December, the first of two vessels under construction for the Imperial Oil Co. These boats are being specially built for carrying oil on the Great Lakes, but the equipment includes all the necessary appliances for ocean service. Principal dimensions: Length, 258 feet; beam, 43 feet; depth, 18 feet. The large freighter for which a contract was recently closed, is now in course of construction and will employ a considerable number of hands during the winter. Particulars of this boat are as follows: Length, 550 feet; beam, 58 ft.; depth, molded, 31 ft.; gross tonnage, about 8,000; deadweight on 19 ft. 6 in. mean draft, 11,000 tons. Three Scotch type boilers each 13 ft. diameter by 11 feet long, will be installed, the triple expansion engines having cylinders 24 in., 40 in., 66 in., dia. by 42 in. stroke. Other launches included a steel steam hopper barge for the Department of Public Works, Ottawa, for use on the St. Lawrence River. This barge is self-propelled, with the following dimensions: Length, 187 ft.; beam, 32 ft.; depth, 14½ ft. The usual quota of general repair work has been completed with encouraging prospects for a good share of this class of work during the ensuing months. The production of 18-pdr. shrapnel and 4.5 high explosive shells has been, as elsewhere, an important development at this plant.

Polson Ironworks, Toronto

The accompanying tables indicate at a glance the substance of the shipbuilding and marine engineering work completed and in process at the yards of the Polson Ironworks, Toronto. In addition to what is there stated, a considerable amount of new and repair, general and stationary engineering and boiler construction has been put through during 1915. Shell production has formed a quite important feature of the total output to the year's credit, and we are informed that in every direction of the firm's activities, the prospects for the ensuing year are in every respect encouraging.

Repair Work, 1915— Polson Ironworks, Toronto

Name of Vessel.	Owners.	Description of Repairs.
Ontario No. 1	Ontario Car Ferry Co. Can. Government	New H.P. cylinder port engine. New firehold floor. Patent stern gate similar to No. 2. Portable hatches over engines. Boilers electric welded, and general overhauling.
Dredge No. 117	Dept. Public Works	General overhauling.

Vessels Completed 1915—Polson Ironworks, Toronto.

Name of Vessel	Yard No.	Type	Principal Dimensions	Gross Tonnage	Engines	Boilers	Speed	Designation	Date of Launching	Port of Registry	Owners.

Ontario No. 2	126	Car Ferry	Length 318'-0" Breadth M. 54'-0" Depth M. 20'-6"	5567	2-Triple exp'n 20½"-33"-54" 36"	4-Scotch 14' dia. 12'-0"g. Howdens Draught	15 miles	Great Lakes	April, 1915	Montreal	Ontario Car Ferry Co.
Wanda III.	127	Yacht	Length 94'-0" Breadth M. 12'-0" Depth M. 6'-0"		Triple exp'n 9"-13½"-20" 11"	1-Thornycroft 1220 sq. ft. H. S.	18 miles		May, 1915	Toronto	Mrs. T. Eaton
Patricia	128	Motor Tug	Length 36'-0" Breadth M. 9'-6" Depth M. 4'-0"		30 H.P. Heavy Duty Gasoline		10 miles		June, 1915		Hudson Bay Co.

Kingston Shipbuilding Co.

During 1915 no new vessels were built at the plant of the Kingston Shipbuilding Co., Kingston, Ont. The amount of repair work was well up to the average, and in the matter of the immediate future in this respect, the following vessels are in hand:—Keyport, repairing stem damage; Keywest, Keybell, Keyvive, Saskatoon and Arabian, repairing bottom damage.

Western Drydock and Shipbuilding Co.

No new tonnage construction work appears on the 1915 record of the Western Drydock & Shipbuilding Co., Port Arthur, Ont.; it will be noted, however, that the ship repairs undertaken were quite heavy. An addition to the regular line of work was the manufacture of light tractors for farm work, twelve carloads of which were shipped to the Western provinces. Owing to the abnormally high price of steel and unsatisfactory deliveries, any increase in activity during the early part of the year is not looked for unless an unexpected change in conditions takes place. Repair jobs in dry dock during season of 1915 included the following steamships: Paliki, 17 shell plates and general overhauling for classification with Lloyds; Turret Chief, partially reconstructed, including the replacing of 119 plates; Frater Taylor, 14 plates and 19 feet of stem; Turret Cape, 21 plates; Glenlivet, 26 plates; Pellatt, 1 plate; Glenlyon, repairs to top and hatch coamings; Collingwood, 11 plates; A. E. Ames, 22 plates; Meaford, 38 plates; Glenfinnan, 25 plates; Lehigh, 1 plate; Inland, 26 plates.

Canadian Vickers, Ltd.

There are at present under construction at the plant of Canadian Vickers, Ltd., Montreal, the following vessels for the Canadian Government:—Steel twin screw icebreaker, of length over all, 292 ft., 57 ft. 6 in. moulded breadth, and 32 ft. moulded depth; steel twin screw centre ladder and hopper barge loading dredger, of length over all, 292 ft. 1½ in., 48 ft. moulded breadth, and 20 ft. 6 in. molded depth. During the 1915 season of navigation, twenty-four vessels were docked and repaired on the floating ship dock Duke of Connaught. In addition, repairs were carried out on a large number of vessels afloat. The foregoing is altogether exclusive of naval armaments or war munitions work.

M. Beatty & Sons, Welland, Ont.

In addition to a considerable number of repair jobs carried out on vessels plying between Port Colborne and Montreal, M. Beatty & Sons completed during the past year the 20-inch, all-steel, hydraulic dredge Primrose to the order of the Canadian Dredging Co., Midland, Ont., for service on Section 5 of the new Welland Ship Canal. They also built and completed a steel fishing tug for Misener & Tedford, Port Burwell, Ont. Alterations are at present proceeding on the steamer Algonquin, preparatory to that vessel entering ocean service next spring. The steamer Nyanza is also being overhauled, and prospects are quite equal to the average of former years in the matter of refitting lake craft wintering at Port Colborne and elsewhere.

MANITOBA'S SHARE OF RAILWAY PROGRESS

EVERY mile of steel that has been, is being or is to be laid in the four Western provinces is of value to the province of Manitoba, and to some extent to the city of Winnipeg, which is the only through connecting point between the east and west in Canada. The three transcontinentals pass through Winnipeg and through Manitoba, and the value of this city and this province as a shipping centre is added to by every mile of new railway built further west.

The growth of the mileage of Canadian railways reads like a miracle, and is shown in the following comparative statement:

1867	2,278
1877	5,782
1887	12,184
1897	16,550
1907	22,452
1914	20,795

The Canadian Bankers' Journal sums up the story of railway building thus: "From Confederation to 1887, a period of twenty years, we added 9,806 miles of railway to the aggregate mileage of the Dominion; whereas in the succeeding 27 years we added 18,611 miles. Putting it in another way, so as to bring the angle of comparison into sharp relief, we constructed an average of 490 miles per annum during the two decades following Confederation, and during the past seven years have built at the rate of 1,192 miles per annum. We have gained momentum as we proceeded, and when the war came along last August we were going a great deal faster than ever; for at that time we actually had 5,521 miles of line under contract, 3,417 miles ready for train service, and 2,443 miles in operation, a total of 11,381 over and above the 30,795 given as the official mileage for 1914."

The Dominion government, provincial governments and municipalities have given liberally to railways, and the province of Manitoba has not been behind in its guarantees and subsidies. Up to the 30th of June, 1914, the Dominion and provincial Governments had authorized guarantees on railway bonds to the amount of $406,259,165, the account in detail standing as follows, according to the Journal of the Canadian Bankers' Association:

Dominion	$188,965,062
Manitoba	25,221,580
Alberta	55,810,450
Saskatchewan	41,625,000
Ontario	7,860,000
British Columbia	7,860,000
New Brunswick	6,063,000
Quebec	392,000
	$406,259,165

These figures show that Manitoba has been a little more conservative in guaranteeing railway bonds than the other Western provinces, having become liable for less amounts than either Alberta, Saskatchewan or British Columbia, the Manitoba total guarantee being less than half of Alberta's, and less than a third of British Columbia's.

Of the new mileage constructed and under construction, eighty per cent. is located in the Western provinces, and the editor of the above quoted journal remarks that "No one would dare to put a limit on the probable development of those provinces after the disturbance created by the present war has subsided."

The gross earnings of the Canadian railways in 1914 reached the large total of $243,083,539, and the 1915 will be even larger. The following comparative statement is interesting, showing the earnings of the railways since Western development was first started:

1877	$ 19,470,539
1887	38,841,609
1897	52,353,276
1907	146,738,214
1914	243,083,529

Eight Canadian railways last year paid a dividend on common stock, the dividend payments totalling $24,522,264.

CANADA'S TRADE WITH BRITAIN

OFFICIAL figures of trade between Canada and Great Britain, forwarded from London by the Canadian Associated Press, throw an interesting light on the preliminary return for the month of November issued from Ottawa a week ago.

Large increases in British imports of Canadian grain, flour and food articles of various description constitute the main feature of the return. In a list of ten articles ranging from wheat to lobsters, the figures show an advance from £2,156,000 a year ago to £3,239,000, a gain of about 50 per cent., although imports of like articles in November last year were on a fairly large scale.

Except in wool, pig iron and steel bars, British exports to Canada for the month were generally lower. Some of the leading figures compare as follows:

Imports from Canada

	1915.	1914.
Wheat	£1,860,837	£1,401,146
Wheatmeal & flour	300,505	96,174
Barley	100,922	14,771
Oats	12,475	40,699
Bacon	314,631	91,446
Hams	26,186	8,726
Butter	44,730	336
Cheese	447,459	466,860
Canned salmon	66,242	36,971
Canned lobsters	66,064	224

Exports to Canada

Spirits	36,393	54,767
Wool	29,080	9,877
Pig iron	15,362	873
Wire	998	1,811
Galvanized sheets	2,473	26,486
Tinned plates	3,758	16,967
Steel bars	16,456	4,788
Pig lead	1,015	1,232
Cutlery	5,015	6,226
Hardware	1,652	2,910

Montreal, Que.—From January 1 to December 22, 1915, the building permits totalled 2,053 of a value of $5,635,921. These figures are for the city of Montreal only, as although Maisonneuve, Verdun, Outremont and Westmount are within the limits of Montreal, they are each separate municipal corporations.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, Que, Dec. 27, 1915.—The passing of Christmas week, with its accompanying slight relaxation from business, has not been signalized by any marked occurrence in the industrial situation. Recent developments in Britain point to the probability that the organization of industries in that country is now very well in hand, reducing the likelihood of continued dependence for supplies on sources outside the Empire. Activities with this end in view have been in progress for some time, official evidence of the fact being afforded by the recent restriction of machinery imports.

The reaction of this will be felt in a general easing of the present tension in both raw and finished products, although the present domestic activity in the States will tend to maintain the Canadian situation unaltered for some time.

Pig Iron

The market is quiet with no change. Until present contracts are nearing completion, no decided tendency in either direction is expected to arise.

Steel

Congestion remains unrelieved. All available producing capacity is more than fully booked, and additional production has not yet been available to mitigate the situation. The absence of official indications regarding the continuance of shell contracts is causing some slight comment and may possibly retard the further rise in material in general for this class of work. Increased activity in general lines is looked for the beginning of the year, but no price changes are noted on the market.

Machine Tools and Supplies

The possibility of relief in the machine tool industry was somewhat strengthened by the restriction of imports to Britain on the part of the authorities there. The conditions of the license under which importations are allowed restricts the business to firms of established reputation, several of whom have already acted as channels for the distribution of Canadian products. The continuance of desirable export business from this country will continue if not increase along certain lines, but if the development is due, as some parties maintain, to the sufficiency of home equipment, purchasers in this market may reasonably expect some relief.

Supplies generally are unchanged, a slight upward tendency being shown in some brands of sheets. The tool steel situation remains unchanged with drills and small tools generally in brisk demand.

Metals

The market is still strong, an upward tendency being noted in several lines, especially in copper. Lead also continues strong.

Copper.—Last week's advance of $10 per ton has been more than continued, an increase of $20 per ton bringing it up to $23 per hundred. Electrolytic copper shows an even greater advance, rising from $21.75 to $23, while the prevailing tendency is further shown by the advance in castings to $22, an increase of 75c per hundred.

Tin.—Business continues quiet, no further developments having been reported regarding possible delays to shipments from abroad. Prices continue at 45c per pound.

Spelter.—No apparent activity has been displayed during the week. The market continues firm at 21c per pound.

Lead.—Last week's upward movement has been more than maintained, an increase of 15c bringing it up to $7 per hundred. As no increase in consumption has been noted, this change would indicate a continued firmness in demand.

Antimony.—This continues steady with no developments of note. Supply is well up to demand with price unchanged at 42c per pound.

Aluminum.—The decline of 2c reported last week marks the extent of the drop. Any considerable decrease cannot be expected as long as the demand for military requirements continues. The price remains at 68c per hundred.

Old Materials

The market for scrap continues good, all lines being steady with marked increases in a few. Increased demand has caused a stiffening in iron, No. 1 wrought advancing to $11.50 per hundred, an increase of $1, a similar movement being repeated by No. 1 machinery cast iron. No. 1 machine composition continues strong at $12.50. Copper shows marked firmness in sympathy with raw material, an advance of 75c per hundred bringing it up to $17. Aluminum and lead are unchanged.

Toronto, Ont., Dec. 30.—The industrial outlook at the close of the year is distinctly encouraging, and conditions are unquestionably better than were anticipated early in the year. Twelve months ago the country had recovered from the slump which immediately followed the outbreak of the war, but at the same time trade was quiet and there was little definite assurance of any marked improvement in industrial prospects. Within a short time, however, large war orders began to be placed in Canada and the whole outlook changed completely, numerous factories starting overtime on equipment necessary for Britain's armies; consequently conditions improved in many industrial centres. This industrial activity, although due in large measure to war orders, especially in the early stages, has had the effect of stimulating domestic trade. The record crop has also added its quota to the general prosperity prevailing and has been of material assistance in restoring in business circles that confidence in the future so necessary for industrial development.

While trade has been gradually improving prices have been advancing and cost of raw material rising all the time. This year has demonstrated more so perhaps than any similar period, the important part which the steel trade plays in the development of a country. As soon as the steel trade became unusually active and prices of iron and steel began to rise, there followed a general advance in finished steel and iron goods affecting the entire community. This condition has been prevailing for some time and the top of the market has not been reached yet. There is not the slightest doubt but that prices will continue to advance during the first few months, at any rate, of 1916, at which time other influences may bear on the situation and continue to stiffen the market. How long present conditions will last depends upon the duration of the war, and this latter is impossible to foretell. The obvious policy under the circumstances, however, is for manufacturers to organize their particular business so as to take advantage of any export demand that may develop as a result of the war.

Prices on all steel products continue to gradually advance and higher levels are expected in the near future. In the machine tool market business is fairly active, but the holiday season has restricted trade to some extent; however, some enquiries have been received for lathes for the larger shells. The metal market is quiet this week, being also under the influence of the holiday season. There are no price changes to note, although these are for the most part firm.

Steel Market

The iron and steel market at the end of the year 1915 is in an exceptionally strong position. The demand is great and prices have attained a level never before known in the history of the trade in Canada. The steel companies, even with the large extensions to their plants, are operating at capacity and when the

boom subsidies will be in a position to handle an extremely large volume of business in normal times. The profits made during the year have placed the companies in a sound financial position which will place the steel trade on a firmer basis than formerly. The market is very firm and prices on all steel products are gradually going higher. Boilers and structural rivets, ¾-in. and larger, have advanced and are quoted at $4. Brass wood screws have advanced again. Higher prices for boiler plates and tubes may be announced shortly, while other lines are also expected to advance.

There is no change in the galvanized sheet situation which is very unsettled. Black sheets continue to advance, while spelter and acid are still high in price with little prospect of being cheaper for some time. There is still a considerable range in prices of galvanized sheets, and some makes are practically out of the market. Mills producing black sheets are running full time and have a large amount of work ahead. Black sheets, No. 20 gauge, are being quoted at a 2.50c to 2.60c basis, and blue annealed, No. 9 and 10 gauge, 2.25c basis, Pittsburgh. An extraordinary situation, closely connected with the steel trade, has arisen in the States. Railroads running into New York have placed an embargo on all shipments of iron and steel products destined for export. The freight yards have been gradually becoming more congested with export shipments for some time, due to shortage of ocean tonnage and heavy export shipments. This serious situation can hardly be relieved unless more tonnage is requisitioned to take care of the ocean transportation. The embargo, while being of material relief to domestic consumers, does not appear to be making the market any easier. Prices continue to advance and some authorities believe the market to be in a top-heavy condition. Prices on contract bars, plates and shapes, now generally 1.80c Pittsburgh, are at the highest level since the formation of the U. S. Steel Corporation. Bessemer and open-hearth billets have advanced again and are now quoted at $32 and $33 per gross ton, Pittsburgh, respectively. Forging billets are unchanged at $52, Pittsburgh.

Pig Iron

The market is quiet but strong with a tendency to higher prices. The furnaces are operating at capacity as the demand for steel-making pig continues heavy. Prices of grey forge, Pittsburgh, have advanced to $18.10 per gross ton, while Hamilton and Victoria iron are unchanged at $24 per ton.

Old Materials

The market is firm and prices generally unchanged. A good demand for scrap copper continues and prices are very firm. Heavy melting steel is also active and prices firm. Supplies of old aluminum are being quickly taken up and prices will go higher.

Machine Tools

A very prosperous year for dealers and builders of machine tools is closing. Local dealers have been remarkably busy for practically the entire year The heavy demand for both new and second-hand tools has been unprecedented. At the present time machinery houses are not so busy as during the summer but they still have plenty of enquiries and orders on hand. An interesting feature during the year has been the development of special tools for making shells and shell parts, which has been the means of keeping many machine shops actively employed. Prices of machine tools have increased considerably during the year, due to increase in cost of raw materials and higher cost of production. The increase in the tariff early in the year also affected imported machinery.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

Supplies

Prices of some lines have advanced and other price changes are expected during the early part of 1916. The heavy demand for lard oil has caused an advance, being now quoted at $1.10 per gallon. Gasoline and benzine have advanced 2c and are now quoted at 27½c and 27c per gallon respectively. Coal oil is also 2c higher. The serious shortage of crude oil and the big demand for gasoline have created a serious situation, and prices of gasoline are almost certain to go higher. Linseed oil and turpentine are unchanged, although higher prices are expeced for the former in the near future. Another advance in cotton waste is expected in the New Year. Prices of small tools are expected to advance early in 1916.

Metals

There is little of interest to note in the metal market this week, it being under holiday influence. There are no important price changes to note, the market being generally steady. The tin market is unsettled on account of possible interference with shipments of tin in the war zone. The situation in the copper market is strong and higher prices are looked for. The spelter market is quiet and firm. It is reported that a bounty on spelter is being advocated in England to encourage the industry. The lead market is firm and unchanged while antimony is very quiet. Aluminum is weaker but unchanged. There is no change in prices of solder.

Tin.—There is considerable uncertainty in the tin market owing to the possibility of shipments being lost at sea or some new British regulation affecting the transportation of tin. The market has been quiet over the holiday period and trading has been almost suspended. Quotations are unchanged at 43c per pound.

Copper.—The copper situation is a very strong one and higher prices are looked for in the near future. The British Government has contracted for many thousand tons of copper in the States for delivery during 1916, but the price has not been definitely disclosed. There is a scarcity of spot copper, and consumption is reported to be greater than production; the demand continues heavy. Local quotations are unchanged at 21¼c per pound.

Spelter.—The market is quiet but very firm. Inquiry has been light but some business has been done, consumers being inclined to wait developments. The exports from the States continue heavy, and an increased demand is expected. Quotations are unchanged at 19c per pound.

Lead.—The situation is unchanged and the market is very firm with an upward tendency. Trading has been light on account of the holiday season. The "Trust" price of 5.40c, New York, is being maintained. Lead is quoted locally at 7c per pound.

Antimony.—The market is quiet but very firm for prompt and January deliveries, and there is good enquiry for futures. Consumption of antimony continues heavy and is getting ahead of production. Local quotations are firm and unchanged at 40c per pound.

Aluminum.—The situation is unchanged with the market a trifle easier. Aluminum is quoted at 65c per pound.

Winnipeg, Man., Dec. 18.—While most of the shops in Winnipeg are busy, they are nearly all busy on shell manufacture, and mostly on 18-pdrs. There is some doubt, now that work is to be let out by tender, whether contracts will be coming to Winnipeg in future, as wages and cost of material are higher than in the East. In view of this uncertainty, it is rumored that some firms have cancelled their orders for special machinery which they were contemplating installing.

Considerable satisfaction is felt here

over the announcement that shells are to be made at the N.T.R. Transcona Shops. Equipment had already been purchased and installed, and shells were being made in these shops many months ago, although recently work was suspended. The contract has now been resumed, being under the auspices of a concern formed for the particular purpose. As the Transcona shops had passed from the control of the G.T.P., making it difficult for them to carry out their shell contract, an arrangement was made with the approval of the Imperial Government to transfer the order to the Transcona Shell Co.

As already stated, the necessary machinery was already in the shops, and all that was required was some transmission equipment, orders for which were placed with Winnipeg houses. This consisted mostly of shafting and hangers. While the demand for machine tools is good in Western Canada, the supply is not equal to the demand. A firm who placed an order for a number of lathes with a local supply house were told that delivery could not be made until next fall, which is a long while to wait for a firm anxious to get down to business. One of the largest machinery houses here has shipped every iron-working machine they had in stock to the East, and are now without stock of any kind. Furthermore, they are afraid to secure stock on the present high market, especially when it is doubtful whether further orders for shells will be coming this way, although it is rumored that a firm in Regina has secured a contract to manufacture 20,000 60-pdrs.

Structural Firms Disappointed

Considerable disappointment is expressed by structural firms here that, with such a large crop, more business was not available for grain elevators. The lumber business, which has been in deplorable shape for three or four years, is recovering sharply, and owners of saw mills are making repairs and installing new machinery in anticipation of a revival of business. This is a result of the good crop. Farmers have money, and will be using considerable lumber on their farms during the coming year. There is a brisk demand for woodworking machinery.

The demand for transmission equipment has been fair, same being required for general repairs to machine shops, laundries, saw mills, etc. There has also been a demand for transmission supplies from flour mills, a number of which have been rebuilt. Laundry machinery has been one of the best selling lines during the past two months, strange to say. There has been a fair demand for electric motors locally. The boiler trade is quiet, the few selling being for heating purposes, or for country plants. A distinct improvement has been observed in the demand for bar iron.

Lack of Shell Orders

While most of the Winnipeg machine shops and other engineering establishments are busy on the manufacture of shells, and while the railway shops at Transcona are beginning work on a large contract, and other companies are being organized here for shell manfacture, there is a feeling that Winnipeg has not been treated square in this matter. The head of one of the largest shops expresses himself in the following words: "We have a large capacity in Winnipeg for making shells, and could turn out from 50,000 to 60,000 per month, which could be increased to 100,000 by the purchase of additional equipment. Our chief trouble here has been shortage of material, and we have been delayed continually by difficulty in getting component parts, particularly copper bands. These are being shipped from the East, as we have not the facilities for making them here.

"We have been making 18-pdr. high explosives right along, and have been unable to secure orders for anything else. There are no plants idle here at present, but there probably will be when contracts are awarded by tender. We would instal new equipment if we got the orders, and we have got as good credit as any firm in the East. We could finance any amount of equipment required."

The 1915 Crop

The big crop of 1915 has been the salvation of Western Canada, and it is freely predicted that if there is an equally good crop in 1916, building will start again in great style. As it is, there is little building going on in the towns and cities—that is, compared with the amount of construction work of two years ago. The farmers are building, but it will be mostly lumber they require, and the cheaper kind of hardware. This has, however, given a stimulus to the sale of heavy hardware, such as iron and steel bars, sheets, etc., and a revival in the lumber business is expected, which is already having its effect on the demand for saw mill machinery and transmission supplies.

All the trades have benefited by the crop, particularly hardware, grocery and dry good trades. When the farmers secured money for their crops, they began to buy things which they had been unable to afford for years, with the result that storekeepers at country points found themselves unable to cope with the demand, having allowed their stocks to run exceedingly low. Consequently orders were wired to Eastern jobbers, asking immediate delivery, which in many cases was impossible, the jobbers themselves having failed to anticipate such a heavy demand. The jobbers in turn fell back on the producers, who were also unable to make immediate deliveries. The result in the case of groceries was that supplies commenced to arrive around Christmas, almost too late to be of any use to the dealer. In the meantime, the farmer turned to his mail order catalogue, but even there found difficulty in securing what he wanted at once.

Hardwaremen Busy

Winnipeg hardware jobbers have not experienced such a period of good business for many years. They are putting through carload orders, which is very unusual at this time of the year. They are busy from the basement to the ceiling, in every department. Particularly pleasing is the fact that the West is buying sporting goods, which is a luxury the farmer has been unable to afford for several years. The man who had an old gun made it last out over the period of depression. He is now buying a new one. Sporting goods is a line that the hardware merchant can soon sink a lot of money in, and he would not be buying so freely if he were not sure of disposing of it.

As an indication of what the big crop means to the West, it is only necessary to cite the case of Herbert, Sask. Last year this town raised thirty ears of grain, which was all taken by the local mill. This year Herbert has raised 3,000 cars, and by the middle of December had only been able to ship 1,500 cars. The crop in Manitoba averaged twenty-seven bushels to the acre, whereas in normal years it only averages about seventeen bushels. Cases are cited of farmers growing sufficient grain to pay for their farms.

Shipping Casualties in November.—The number and net tonnage of British vessels, respecting the loss of which reports were received at the Board of Trade during November, and the number, and the number of lives lost, were: —Sailing vessels, thirty-five, net tonnage 4,977, lives lost six; steamships fifty-three, net tonnage 61,072, lives lost 646. Among this number were twenty steamers of 48,523 tons, sunk by German warships, ten steamers of 4,654 tons, sunk by mines, and one steamer of 864 tons, sunk by a German warship or mine. Four hundred and ninety-five lives were lost in steamers sunk by German warships, of which 315 were lost in the Ramazan, and 167 in the Marquette, 58 in steamers sunk by mines, and 20 in steamer sunk by a German warship or mine.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

Engineering

Toronto, Ont.—The Universal Tool Steel Co. will build an addition to their plant to cost $7,000.

Lunenburg, N.S.—The foundry owned by Leonard G. Holder has been completely destroyed by fire.

Marysville, N.B.—The Canadian Cottons, Ltd., will install an auxiliary power plant and transmission lines.

Owen Sound, Ont.—Keenan Brothers, Ltd., are in the market for an engine lathe and plain milling machine.

Ottawa, Ont.—E .Williams, 172 Glenora Avenue, is receiving prices on steam boilers, hot water boilers, electric pumps, steel tanks, etc.

Orillia, Ont.—Work has been started on the erection of an addition to the factory of the National Hardware Co., at an estimated cost of $20.000.

Arnprior, Ont.—McLachlin Bros. propose to add to their plant a mechanical pulp mill with a capacity of 100 tons daily. Estimated cost, $500,000.

Port Arthur, Ont.—The Western Machinery Co. will shortly move into larger premises on North Court Street, and will install a quantity of new machinery.

Hamilton, Ont.—The Monarch Machine Tool Co. are about to occupy the factory at Young and Ferguson streets, and will make alterations to the building.

London, Ont.—The London Gas Engine Co. plant was recently purchased by W. H. Heard of the Spramotor Co. Additions costing $40,000 will be made to the plant.

Montreal, Que.—The Canadian Electro-Products Co., incorporated with a capital stock of $500,000, with J. S. Norris, Howard Murray and Julien C. Smith as directors, has purchased the Record Foundry Building here, and is installing machinery for the manufacture of shells and other munitions. It will also install an electric furnace.

Municipal

Midland, Ont.—The by-law to raise $13,000 for waterworks extensions has passed.

Port Credit, Ont.—A hydro-radial bylaw will be submitted to the ratepayers on Jan. 1.

Melford, Sask.—The town council propose to purchase one 240 h.p. oil engine for the civic power plant.

Bagotville, Que.—The construction of an electric lighting system at an approximate cost of $7,000 is contemplated.

Cornwall, Ont.—It is proposed to spend $25,000 on waterworks extensions and improvements at the pump house.

Watford, Ont.—The town council contemplate installing a hydro-electric system. A bylaw will be voted on in January.

Edmonton, Ont.—The by-law to authorize an expenditure of $274,966 on a sewage disposal plant has been passed by the ratepayers.

Aylmer, Ont.—The installation of an electric pumping plant and extensions to the lighting system are being considered by the Board of Works.

Tara, Ont.—It is intended to spend $7,500 on a hydro-electric distribution system. A by-law will be voted on by the ratepayers on Jan. 3.

Wellesley, Ont.—An expenditure of $7,500 is contemplated on a hydro-electric system. A by-law will be submitted to the ratepayers on Jan. 3.

Gravenhurst, Ont. — Extensions are proposed to the street lighting system to cost $3,500.. A by-law will be submitted to the ratepayers in January.

Windsor, Ont.—A by-law has been passed authorizing the construction of extensions to the hydro electric system at an approximate cost of $50,000.

Springfield, Ont. — A by-law was submitted by the town council on December 29 to provide for the installation of an electric plant at an approximate cost of $5,000.

Komoka, Ont.—The Lobo township council will submit a by-law to the ratepayers on January 3 to authorize the borrowing of $4,000 for the construction of a hydro electric system.

Cobourg, Ont.—A by-law will be voted on by the ratepayers on Jan. 3 to authorize a loan of $5,000 to George Thompson to assist in the building of an extension to the Cobourg Steel Co. plant.

Newcastle, N.B.—The Town Council will install a motor-driven centrifugal pump of 350 gal. per minute capacity at its waterworks at a cost of $2,000. D. A. Jackson is electrical engineer.

Sherbrooke, Que. — The city council will shortly call for tenders on general repairs and improvements to the power plant. Plans are also being prepared by consulting engineer, M. A. Sammett, Montreal.

General Industrial

Chatham, Ont.—There is a possibility of a shoe manufacturing concern taking over the plant of the Wolverine Brass Co.

Saskatoon, Sask.—The Golden West Milling Co. will start work immediately on the erection of a flour mill at Wakaw, Sask.

Cap Madeleine, Que.—The Union Bag & Paper Co. of New York are considering the erection of a print and sulphide mill here.

Prescott, Ont.—Extensive repairs are being made on the building which the Newell Mfg. Co. have purchased for their local factory.

Woodstock, Ont.—Fire of unknown origin destroyed the flour mill of Maycock & Harris of Princeton on Dec. 27, entailing a loss of $10,000.

St. Mary's Ont.—Messrs. Weir & Weir have taken over the Victoria Mill, which will be overhauled and equipped with flax mill machinery.

Toronto, Ont.—Fire on December 24 destroyed the Martin Corrugated Paper Co.'s factory, the loss being estimated at $225,000, including machinery valued at $125,000.

Toronto, Ont.—The Goodyear Tire & Rubber Co., of Akron, Ohio, are going to establish a branch in Canada, and have completed arrangements whereby a plant will be located in New Toronto, near here. A by-law will be voted on by the ratepayers on Jan. 8 to grant a fixed assessment.

Trade Gossip

The North American Chemical Co have increased the capital stock of the concern to $100,000.

JOHNS-MANVILLE SERVICE

JOHNS-MANVILLE SERVICE COVERS THE CONTINENT

Goods of known quality backed by a known reputation are unquestionably the safest goods to buy.

For over half a century the name Johns-Manville has stood as a guarantee for products of proven excellence.

J-M Asbestos Roofings put an end to your roofing expense

These roofings are non-corrosive as well as weather-proof and time-proof, and will last for a generation.

Some in use for twenty to thirty years—and still good!

Contain no organic material—made only of Asbestos Fibre and Trinidad Lake Asphalt. Never need painting. Are fire retardant almost to a fire-proof degree, and non-conducting.

Furnished in "Built-up" type for flat roofs and in "Prepared" type for sloping roofs.

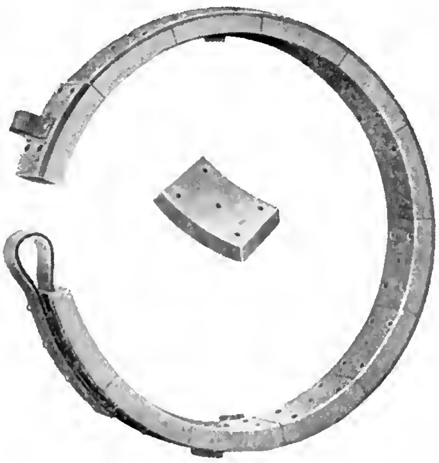
J-M Asbestos Built-up Roofing has a smooth surface and is very much lighter than tar-and-gravel.

Your own men can easily lay J-M Asbestos Ready Roofing with J-M Vise-Grip Roofing Cleats and make a perfect job.

Register your J-M Roof with us and we will see that it gives you full service under J-M Roofing Responsibility. Ask about this.

Canadian Pacific Railway Train Sheds. Windsor St. Station, Montreal. J-M Asbestos Roofings. The Dominion Bridge Co. and Geo. A. Fuller Construction Co., Contractors.

Does your braking material satisfy these three reasons? J-M Asbesto-Metallic Brake Blocks Do



If you are interested in a material for your brakes and clutches that will operate for months without appreciable wear, if you can use a brake block that will not even char under great frictional heat and that is unaffected by water, climate, oil or grease, then try J-M Asbesto-Metallic Brake Blocks—*For structural reasons.*

If you need accurate braking—a brake that will respond to the slightest pressure or the "hardest jam" without feeling the shock, try J-M Asbesto-Metallic Brake Blocks—*For operating reasons.*

If you want your brake to be a "safety" brake, that will not slip or creep, even in the presence of oil, grease or water, try J-M Asbesto-Metallic Brake Blocks—*For safety reasons.*

What more can we say of this material except to suggest that you try it on your brakes and clutches?

Made in any shape and size to suit your requirements.

Let us have a sketch along with your request for particulars.

The Canadian H.W. JOHNS-MANVILLE CO., Limited

TORONTO MONTREAL WINNIPEG VANCOUVER

The Munro Steel & Wire Works, Ltd., Winnipeg, are amalgamating with the Hero Manufacturing Co.

The Ford Motor Co. of Canada, Ltd., Ford, Ont., will increase the capital stock of the concern to $10,000,000.

Niagara Falls, Ont.—The Spanish Niagara Tramway Co. have nearly completed the aerial tramway over the whirlpool.

The Canadian Ice Machine Co., Toronto, Ont., have been awarded a contract for a refrigerating plant by the Windsor Ice & Coal Co., Windsor, Ont.

Much Hydro Power in U.S. Available.—Government experts estimate that of the 26,000,000 horse-power which it is possible to develop hydro-electrically in the United States 19,000,000 horse power lies west of the Rockies.

Tungsten Ore Exports.—By an order dated October 30, 1915, the exportation from British India of tungsten and wolframite or any other ore of tungsten is prohibited except under a permit signed by the chief Customs officer.

Three Rivers, Que.—The Three Rivers Traction Co., which inaugurated their city line here on the 11th instant, opened on December 21 the extension line to Baptist Island, where the mills of the Wayagamack Pulp & Paper Co. are situated.

Brantford, Ont.—The Hydro-Electric Commission report for the past year shows that a net surplus in the neighborhood of $16,000 to $17,000 over and above the operating expenses and capital account means lowered rates amounting to one dollar per light for the street lighting circuit. The taking of 1,000 horse-power by the Lake Erie will mean a further decrease in local rates.

M. Beatty & Sons, Ltd., Welland, Ont., have received an order from the Confederation Construction Co., contractors on section 3, Welland Ship Canal, for six electric hoists. Two of these are 50 h.p. with single drums; two 50 h.p. with double drums; two 35 h.p. with double drums. All are to be used on the new concrete handling plant which the contractors are building this winter for use on the twin flight locks next spring.

Perpetuate New Industries.—The perpetuation of the industries which have grown up in Canada as a result of shell orders received in this country, has been taken up by the Government, according to an official statement. Following the advice of Lionel Hichens, the British shell expert, the question of assuming permanence to the great industry which has developed in the Dominion in a year has been given immediate consideration. It has been added to the duties of the Economic and Development Commission, and will be perhaps one of the most important matters to be reported on by that body.

Personal

Col. Cantley, president of the Nova Scotia Steel & Coal Co., is not going to England, as was recently reported.

Hon. Frank Cochrane, Minister of Railways and Canals, will leave this week for England. Mr. Cochrane will be away for a month, and will not be in Ottawa when the session opens.

C. C. Johnson, B.A.Sc, has been appointed resident engineer at London, Ont., representing Chipman & Power, consulting engineers, Toronto, who are responsible for the proposed sewage disposal plant.

W. J. McCormack, who has been superintendent for the Northern Navigation Co. at Sarnia, Ont., for some years past, has been appointed manager of the steamers operated by the Algoma Central Railway Co., with headquarters at Sault Ste. Marie, Ont. Mr. McCormack will assume his new duties the first of the year.

M. L. Allard, of Toronto, assistant superintendent of the Dunlop Tire & Rubber Goods Co., was a passenger on board the Japanese liner Yasaka Maru, torpedoed in the Mediterranean. Mr. Allard is safe at Port Said, but has lost everything, including his letters of credit. Mr. Allard has been making a tour of Europe on behalf of the Dunlop Company, and was on his way to the Far East.

Foreman Honored.—A token of the estimation in which William Fourney, machine shop foreman at the John McDougall, Caledonian Iron Works, Montreal, is held, was shown in the presentation by the employees on Christmas Eve of a gold watch and chain, suitably engraved. The presentation was accompanied by an address which referred to Mr. Fourney's consideration for his men and faithful performance of his duty towards the firm.

Tenders

Grand Mere, Que.—Tenders are being called until January 5 for electrical equipment, including a 500-h.p. turbine and generator, switchboard, etc.

St. Hyacinthe, Que.—Tenders will be received up to January 11 for a mechanical filter plant. Plans and speci-

fications may be obtained at the office of Hector Cadieux, city engineer.

Winnipeg, Man.—Tenders will be received at the office of the Greater Winnipeg Water District, up to January 10, 1916, for the supply of rock crushing plant. Specifications and form of tender may be obtained at the offices of the district, 901 Boyd Building.

Toronto, Ont.—Tenders will be received, addressed to the Chairman, Board of Control, City Hall, up to Tuesday, January 11th, 1916, for the supply and delivery of—No. 34, red lead paint for Bloor Street viaduct; No. 74, cast iron special castings for main pumping station. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

Montreal, Que.—Tenders will be received by the Board of Commissioners, City Hall, up till Tuesday, January 4, 1916, for building and erecting at Papineau Avenue pumping station one electrically-driven turbine or high lift centrifugal pump, with electric motor complete. Specifications may be obtained at the office of the superintending engineer of the Waterworks Department, City Hall.

New Incorporations

The National Cash Register Co. of Canada, Ltd., has been incorporated at Ottawa with a capital of $1,000,000, to develop the business already established in Toronto, Ont.

The Western Machinery Co. has been incorporated at Toronto, with a capital of $40,000, to manufacture all kinds of

machinery, boilers, shells, and iron and steel products, at Port Arthur, Ont. Incorporators: Richard Best Roberts, Peter Donald Munroe, and Angus McPherson, of Toronto.

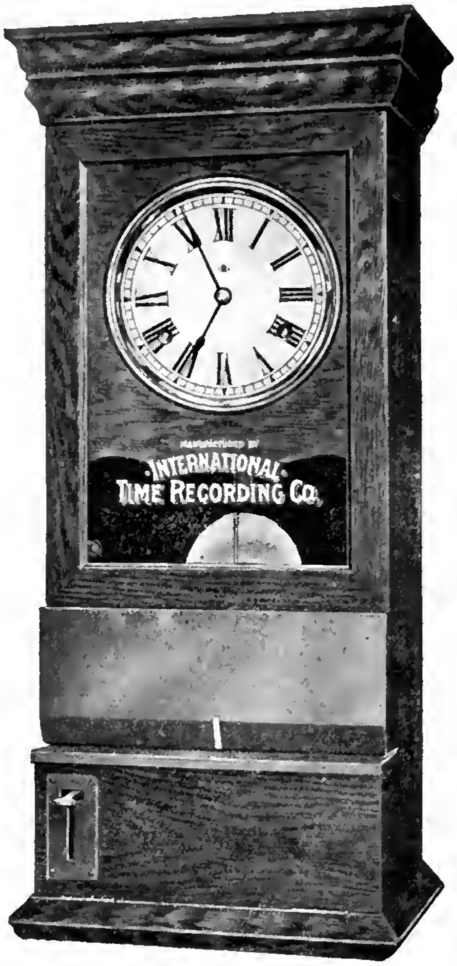
The Consolidated Steel Co. has been incorporated at Toronto, with a capital of $100,000, to carry on the business of iron founders, mechanical engineers and manufacturers of machinery, tool makers, brass founders, metal workers, etc., at Toronto. Incorporators: Wm. Hughes Beatty, Francis Arthur Hammond and Charles Bennett McClurg, all of Toronto.

The St. Maurice Paper Co., Ltd., has been incorporated at Ottawa with a capital of $10,000,000 to manufacture and produce mechanical and ground wood pulp, paper, etc. Head office at Montreal. Incorporators: Alexandre Chase-Casgrain, Errol Malcolm McDougall, and Pierre Francois Casgrain, all of Montreal, Que.

Catalogues

Heating Water With Steam is the title of a catalogue issued by the Alberger Heater Co., Buffalo, N.Y. The catalogue deals with the "Alberger" multi-head water heaters for various services and contains views of buildings and plants where they have been installed. The construction of this heater is described fully and reference is made to the efficient heat transmission. Tables for the 1915 U.S. standard pipe flanges, a table of flow of steam through pipes and a table of temperature differences are included. The catalogue concludes with a description of the Ross expansion joint which is also illustrated.

Steam Tables for Condenser Work.—The third edition of this handbook of steam tables has been published by the Wheel Condenser & Engineering Co., Carteret, N.J. The book contains 31 pages, 14 of which cover three tables, No. 1 being a vacuum table and gives properties of saturated steam from 29.8 in. of vacuum to atmospheric pressure. No. 2 is a temperature table and gives properties of saturated steam from 30 degrees to 212 degrees Fah. No. 3 is a gauge and absolute pressure table and gives the properties of saturated steam from 0 lbs. gauge pressure to 200 lbs. gauge pressure. The concluding section contains constants and tables, etc., for the correction of readings. The steam tables are based on the properties of saturated steam given in the latest tables of Marks & Davis and were especially calculated for this book by Prof. Marks.



The Mechanical Cost Keeper

Manufactured by the International Time Recording Company and illustrated above does at least two very important things:

1. **It shows the exact amount of productive labor you are able to charge up against any given job.**
2. **It shows exactly the amount of "non-productive" labor you are paying for but are not able to charge against any job.**

No workman or foreman can force a balance between his productive and his non-productive time. The machine is cold-blooded, accurate and mechanically correct. The Mechanical Cost Keeper throws a searchlight on a very important part of your overhead expense—that is, the non-productive labor in your plant.

We will be glad to send you particulars, or advice, on any Time Recording System you wish to install. We are the largest makers of time recording machinery in the world.

This useful publication may be obtained on application from the Wheeler Condenser & Engineering Co.

Book Reviews

Laboratory Tests of a Consolidation Locomotive, by E. C. Schmidt, J. M. Snodgrass, and R. B. Keller has just been issued as Bulletin No. 82 by the Engineering Experiment Station of the University of Illinois. This bulletin presents the results of a series of laboratory locomotive tests, which constitute the first work of the recently established locomotive testing laboratory of the University of Illinois. The tests were made on a typical consolidation locomotive loaned to the University of Illinois by the Illinois Central Railroad, and the data secured and the results derived therefrom are presented and analyzed in detail. Since this is the first series of tests conducted in the new laboratory, the bulletin includes a description of the laboratory equipment and the methods of testing employed. The locomotive was first tested in the condition in which it was received from service. It was then subjected to certain repairs, and again fully tested. The main purpose of the tests was to determine the general performance of the locomotive and the performance of its boiler and engines after the repairs were made and when the locomotive was in excellent condition. The secondary purpose was to study the effect of some of these repairs upon the locomotive's performance. The locomotive was worked during the tests throughout a range of speed corresponding to that which would ordinarily prevail in service. At each of the various speeds the endeavor was made to vary the cut-off throughout as wide a range as the capacity of the boiler or of the grates would permit. All tests were made with the throttle wide open. The maximum amount of dry coal fired per hour was 11,127 pounds or 224.5 pounds per square foot of grate per hour. The maximum equivalent evaporation per hour was 57,954 pounds or 17.65 pounds per square foot of heating surface per hour. The University of Illinois equipment makes possible the collection of all stack cinders and the information relative to cinder losses which is presented shows these losses to have ranged from 3 to 16 per cent. of the weight of the dry coal fired for what might be considered ordinary service conditions and to have amounted to 27.4 per cent. of the weight of the dry coal fired during one test under extreme conditions of firing and draft. Copies of Bulletin No. 82 may be obtained gratis upon application to W. F. M. Goss, Director of the Engineering Experiment Station, University of Illinois, Urbana, Ill.
